ABSTRACT

Postpartum hemorrhage and obstetric shock are leading causes of maternal mortality, particularly in low-resource settings. The non-pneumatic anti-shock garment (NASG) is a low-technology mechanical intervention designed to stabilize women experiencing early decompensated hypovolemic shock. NASG applies graduated compression from the lower limbs to the pelvis, inducing mechanical autotransfusion and increasing central venous pressure, stroke volume, and cardiac output via the Frank-Starling mechanism. Clinical evidence demonstrates rapid stabilization, including restoration of consciousness, palpable pulses, and urine output in most patients, with observational data showing a pooled relative risk of mortality of 0.52. Doppler studies indicate increased pelvic vascular resistance, supporting hemostasis in uterine atony and genital tract trauma. NASG is cost-effective, with an estimated cost of $21–$65 per disability-adjusted life year (approximately ₹1,900–₹5,500), and can be reused up to 72 times with proper decontamination. Challenges include adherence to cleaning protocols, material wear, and contraindications such as congestive heart failure, pulmonary hypertension, and intrathoracic hemorrhage. Reported adverse events are generally mild, including pressure injuries and peripheral

neuropathy with prolonged use. Despite two decades of documented effectiveness, NASG remains underrepresented in major global guidelines, limiting adoption. Broader integration into clinical protocols and policy frameworks could significantly improve maternal outcomes in resource-limited settings.

Keywords: NASG, postpartum hemorrhage, hypovolemic shock, maternal mortality, obstetric emergency.

INTRODUCTION

Hypovolemic shock secondary to obstetric hemorrhage remains a leading cause of maternal mortality globally, accounting for approximately 70,000 deaths annually, with a disproportionate burden in low- and middle-income countries (LMICs) [1]. Despite advances in uterotonic agents, blood banking systems, and surgical interventions, many women continue to experience critical delays in accessing timely and adequate care, contributing to preventable maternal deaths. These delays are well described by the 'Three Delays' model, which identifies delays in deciding to seek care, reaching a health facility, and receiving appropriate treatment at the facility level [2]. Geographic, financial, sociocultural, and systemic barriers often interact, exacerbating the risk of severe morbidity and mortality. In this context, mechanical interventions that can stabilize women before or during transfer to higher-level care facilities are particularly valuable. The non-pneumatic anti-shock garment (NASG) has emerged as an effective low-technology mechanical circulatory support device capable of reversing early decompensated shock by applying graduated external counterpressure from the lower extremities to the lower abdomen [3]. Unlike its predecessor, the pneumatic anti-shock garment (PASG), the NASG does not require inflation systems, compressed gas, or electrical power, rendering it highly suitable for deployment in resource-limited and austere environments [4]. Over the past two decades, NASG has been increasingly applied in LMICs to manage postpartum hemorrhage (PPH), ruptured ectopic pregnancy, and other obstetric causes of hypovolemic shock.

This narrative review synthesizes current evidence on NASG's pathophysiological mechanisms, hemodynamic effects, clinical outcomes, safety considerations, cost-effectiveness, and implementation barriers. We critically evaluate observational studies, randomized controlled trials, and meta-analyses, highlighting knowledge gaps and proposing future research directions, device innovations, and policy integration strategies to optimize maternal survival in low-resource settings.

Mechanism of Action: Hemodynamic and Vascular Physiology

Device Architecture and Biomechanics

The NASG is a flexible wrap made of neoprene material divided into nine interconnected segments reinforced with polyester fabric and secured with Velcro® straps [5]. It is applied in a distal-to-proximal sequence, starting at the ankles and progressing to the abdomen, enabling staged pressure application akin to sequential pneumatic compression systems [6]. Each segment contains closed-cell polyethylene foam inserts that enhance pressure transmission while minimizing shear stress, ensuring patient comfort and minimizing soft tissue injury. The design permits uninterrupted access to the perineum and lower abdomen, allowing concurrent obstetric interventions such as bimanual uterine compression, intrauterine balloon tamponade, or manual removal of retained placenta without compromising the effectiveness of the garment [7].

Autotransfusion and Central Hemodynamic Effects

The primary physiological mechanism of NASG involves auto transfusion, wherein blood pooled in the lower extremities and pelvic vasculature is mobilized into the central circulation [8]. This results in increased preload and central venous pressure, which, through the Frank–Starling mechanism, enhances stroke volume and cardiac output.

Mean arterial pressure typically rises by 20–40 mmHg within thirty minutes of application [9]. Non-invasive hemodynamic monitoring using techniques such as USCOM and NICOM demonstrates significant improvements in cardiac index and systemic vascular resistance following NASG deployment [10]. The rise in systemic vascular resistance occurs due to a combination of baroreceptor-mediated vasoconstriction and direct mechanical compression of abdominal and pelvic vessels, ensuring adequate perfusion of vital organs during hypovolemic states.

Regional Vascular Resistance and Pelvic Tamponade Effect

Doppler ultrasound studies in postpartum women reveal marked increases in pulsatility and resistive indices in the internal iliac arteries following NASG application, indicating elevated downstream vascular resistance [11]. This suggests a pelvic tamponade effect, whereby external compression reduces arterial inflow to the uterus and adnexa, potentially promoting hemostasis in cases of uterine atony or genital tract trauma. The uterine artery pulsatility index has been shown to increase by approximately 35 percent within twenty minutes of full NASG application, correlating with observable clinical stabilization [12]. These effects are most pronounced in women experiencing class II–III hemorrhagic shock, corresponding to 15–40 percent total blood volume loss, when compensatory cardiovascular mechanisms remain partially intact [13].

Clinical Indications and Efficacy

Primary Obstetric Indications

NASG is indicated primarily for obstetric causes of hypovolemic shock, including postpartum hemorrhage due to uterine atony, retained placenta, or genital tract trauma, as well as ruptured ectopic pregnancy with hemoperitoneum and incomplete abortion complicated by hemorrhagic shock [14]. Its effectiveness is optimized when applied prior to irreversible decompensation, during inter-facility transfers, or while awaiting operative intervention or transfusion of blood products [15].

Secondary and Emerging Uses

Limited case reports describe NASG use in non-obstetric hemorrhage, including traumatic injuries, gastrointestinal bleeding, and septic shock with a distributive component [16]. However, the evidence in these contexts remains sparse, and caution is advised. Historical experiences with the pneumatic anti-shock garment in penetrating torso injuries demonstrated increased mortality due to premature tamponade of non-compressible hemorrhage, underscoring the importance of careful patient selection [17].

Mortality and Physiological Outcomes

Observational evidence consistently demonstrates rapid hemodynamic stabilization following NASG application. Approximately 76 percent of women in shock exhibit recovery of consciousness, palpable pulses, and urine output within thirty minutes [18]. Systolic blood pressure typically increases from a median of 70 mmHg to 95 mmHg, while heart rate decreases from 130 to 100 beats per minute. A meta-analysis of before-and-after studies reported a pooled relative risk reduction of 0.52, corresponding to a 48 percent decrease in case fatality [19]. The only cluster-randomized trial conducted in Zambia and Zimbabwe enrolled 1,458 women across twenty facilities [20]. Although NASG application was associated with improved vital signs, the study was underpowered to demonstrate statistically significant mortality reduction, with a relative risk of 0.78 (95% CI: 0.52–1.17; p=0.23). High crossover rates and contamination between clusters limited interpretability and generalizability of the findings.

Cost-Effectiveness and Resource Utilization

Economic modeling in Nigeria and Ethiopia demonstrates that NASG is highly cost-effective, with an estimated $21–$65 per disability-adjusted life year averted, equivalent to approximately ₹1,900–₹5,500, well below the WHO threshold of three times GDP per capita [21]. The device is reusable between forty and seventy-two times with proper decontamination using 0.5 percent sodium hypochlorite followed by air drying, resulting in an amortized cost of under $10 per use. Despite the theoretical reusability, real-world adherence to cleaning protocols varies, and residual hemoglobin has been detected on approximately 15 percent of garments during field studies [22].

Safety Profile and Contraindications

NASG is generally safe but has important contraindications. Absolute contraindications include congestive heart failure, in which increased preload and afterload may precipitate acute decompensation; pulmonary hypertension, which increases right heart strain; and intra-thoracic hemorrhage, where redistribution of blood volume could exacerbate bleeding. Relative contraindications include lower limb compartment syndrome and deep vein thrombosis, due to risks of ischemia or embolization [23]. Reported adverse events are generally mild and include pressure ulcers over the malleoli or sacrum, peripheral neuropathy associated with prolonged use exceeding twenty-four hours, and reperfusion injury upon rapid removal in severely acidotic patients. Active surveillance systems for adverse events are lacking in most LMICs, and long-term safety data remain limited [24].

Implementation Challenges

Despite demonstrated efficacy, NASG faces several implementation barriers. Training and competency remain inconsistent; a multi-country survey indicated that only forty percent of trained providers felt confident applying the device independently [25]. Training programs vary from brief workshops to multi-day courses, and no standardized curriculum has been endorsed by WHO or other professional societies [26]. Simulation-based education improves retention, but scalability is limited by human and financial resources [27]. Supply chain and reusability present additional challenges. Global consensus on sizing protocols, inventory management, and distribution models is lacking. Manufacturer claims regarding reusability are based on ideal testing conditions, but field studies indicate inconsistencies in cleaning and maintenance. Repeated exposure to bleach solutions contributes to neoprene cracking, foam disintegration, and Velcro fatigue, potentially compromising pressure delivery. Microbial persistence, particularly of bloodborne pathogens such as HIV and hepatitis B, remains understudied, raising infection control concerns [28,29].

Research Gaps and Limitations

Despite over twenty years of NASG deployment, high-quality evidence remains limited. No large multicenter randomized controlled trial powered for mortality exists. Existing trials often lack blinding and rigor in randomization, and observational studies are prone to selection bias. Physiological effects have not been fully explored in specific populations, including anemic, hypertensive, or HIV-positive women. Important parameters such as myocardial oxygen demand, lactate clearance kinetics, coagulopathy, and endothelial glycocalyx shedding remain unexplored. NASG is also absent from major guidelines, including the WHO 2023 Guidelines for Postpartum Hemorrhage [30], ACOG Practice Bulletin No. 183 (2017, reaffirmed 2023) [31], and FIGO recommendations [32], limiting adoption, procurement, and insurance coverage.

Future Directions

Future research priorities include multicountry randomized controlled trials evaluating maternal mortality, organ dysfunction, and lactate clearance. Advanced hemodynamic studies utilizing echocardiography, pulse contour analysis, and near-infrared spectroscopy could provide deeper insights into cardiovascular and tissue perfusion effects. Implementation science approaches are required to optimize task-shifting, supply chain logistics, and infection control strategies. Device innovation may include antimicrobial-coated fabrics, adjustable sizing systems informed by anthropometric modeling, and semi-disposable versions for high-turnover settings. Training integration should focus on pre-service education of midwives, nurses, and paramedics, supported by mobile simulation applications and virtual reality modules to enhance retention and competency. Policy advocacy is essential to secure conditional WHO recommendations, engage professional societies such as ACOG and FIGO, and integrate NASG into emergency obstetric care bundles and referral networks. Broad adoption of NASG aligns with Sustainable Development Goal 3.1 to reduce maternal mortality and could substantially improve maternal outcomes in low-resource settings.

CONCLUSION

The non-pneumatic anti-shock garment functions as a mechanical circulatory support device that stabilizes women in early decompensated hypovolemic shock by facilitating auto transfusion, increasing systemic vascular resistance, and augmenting pelvic vascular impedance. Evidence from observational studies and physiological monitoring demonstrates that NASG use leads to rapid improvements in hemodynamic parameters, including blood pressure, cardiac output, and perfusion, as well as enhanced survival, particularly in low-resource settings where delays in accessing definitive care are common. Despite these benefits, the absence of large, high-quality randomized controlled trials, inconsistent implementation practices, challenges in infection control, and exclusion from major global guidelines have limited its widespread adoption. For NASG to realize its full potential, it must be integrated into comprehensive emergency obstetric care pathways, accompanied by standardized training programs, robust implementation frameworks, and supportive policy recognition. It is not a definitive treatment, but a physiologically sound bridge to life-saving interventions such as surgical hemostasis, administration of uterotonics, and blood transfusion. With strategic investment, ongoing research, and global collaboration, NASG has the potential to become a cornerstone of equitable maternal critical care in the twenty-first century, improving outcomes for women in both low- and high-resource settings.

DECLARATIONS

ABSTRACT

Risk-Based Authentication (RBA) systems analyze contextual and behavioral signals from login events to determine the likelihood of fraudulent or anomalous access. This paper proposes a hybrid modeling framework that combines a Long Short-Term Memory Autoencoder (LSTM-AE) for unsupervised sequence representation learning with a Random Forest (RF) classifier for supervised anomaly detection. The LSTM-AE captures temporal dependencies in per-user login sequences and produces compact embeddings, while the Random Forest leverages these embeddings alongside engineered contextual features to classify login attempts as normal or risky. We evaluate the approach on the publicly available RBA (Login) dataset. Experiments demonstrate that the hybrid model outperforms standalone RF and LSTM-AE baselines on F1-score, AUC-ROC, and detection recall for rare anomalous events. We also analyze feature importances, reconstruction error distributions, and detection latency. The results indicate the hybrid approach effectively leverages temporal structure and tabular feature modeling, providing a robust and interpretable solution for real-world RBA systems.

Keywords: Risk-Based Authentication, Anomaly Detection, LSTM Autoencoder, Random Forest, Behavioral Biometrics, Login Security, Representation Learning

INTRODUCTION

The increasing prevalence of online services has made authentication a cornerstone of digital security. Traditional static authentication mechanisms such as passwords are vulnerable to credential theft, phishing, and replay attacks. Risk-Based Authentication (RBA) supplements standard authentication by evaluating contextual and behavioral signals of each login attempt (e.g., device fingerprint, geolocation, time of day, historical usage) to estimate the risk associated with the attempt. Approaches that can reliably and quickly detect anomalous login behavior are critical to reduce fraudulent access while minimizing friction for legitimate users. Machine learning models—especially those that can capture temporal and sequential patterns—are promising for RBA tasks. Purely tabular models (e.g., Random Forests, Gradient Boosting) excel at learning complex decision boundaries from heterogeneous features but often ignore temporal dependencies across a user's login history. Conversely, sequential models such as LSTM networks capture temporal dynamics but require careful engineering to incorporate non-sequential contextual signals and can be less interpretable. This study proposes a hybrid architecture combining an LSTM Autoencoder (LSTM-AE) for learning temporal representations from per-user login sequences with a Random Forest (RF) classifier that uses those learned embeddings plus engineered contextual features to classify login attempts. The LSTM-AE compresses recent temporal behavior into a fixed-length embedding that encapsulates how a user typically logs in, allowing the RF classifier to make better informed decisions. We hypothesize that (1) temporal embeddings produced by LSTM-AE improve classification performance when combined with tabular features, and (2) the hybrid pipeline balances detection power and interpretability, making it practical for RBA systems.

Contributions of this paper

1. A clear hybrid pipeline combining sequence-level LSTM Autoencoder embeddings with Random Forest classification for RBA tasks.
2. A comprehensive experimental evaluation on an RBA login dataset, comparing baseline and hybrid approaches using multiple metrics and ablations.
3. Interpretability analysis (feature importance and reconstruction errors) and practical considerations for real deployment (latency, retraining schedule, threshold selection).

RELATED WORK

Anomaly detection in login and authentication systems is a well studied problem. Traditional anomaly detection techniques include statistical rule-based thresholds, clustering, and one-class models. Machine learning approaches have been widely adopted: tree-based ensembles such as Random Forests and gradient boosting are strong baselines for tabular risk scoring, while deep learning methods—autoencoders, recurrent networks, and graph models—are increasingly used for modeling complex behavior. Autoencoders, particularly LSTM Autoencoders, have been applied to sequence anomaly detection in domains like IoT, network intrusion, and transaction fraud. The autoencoder is trained to reconstruct sequences of "normal" activity; high reconstruction error signals anomalous events. Hybrid approaches that combine unsupervised feature learning (autoencoders) with supervised classifiers have been proposed in other domains: for instance, using an autoencoder to transform raw data into embeddings fed into a tree-based classifier. This hybrid strategy often delivers improved robustness and interpretability while mitigating label scarcity. Li *et al*. (2022) [1] discussed the integration of AI-driven optimization techniques in drone technology for precision agriculture. Their study highlighted how machine learning models enhance decision-making in crop health monitoring and yield prediction. Singh and Verma (2021) [2] proposed a hybrid CNN architecture for detecting crop diseases using UAV imagery. Their model improved classification accuracy by fusing spatial and spectral features of crop images.

Patel and Shah (2020) [3] focused on IoT-integrated drones that collect real-time field data, including temperature, humidity, and soil moisture, to optimize agricultural operations. The study emphasized the role of wireless sensor networks in supporting autonomous UAV missions. Zhao *et al*. (2023) [4] reviewed Whale Swarm Optimization

(WSO) as a bio-inspired algorithm and its potential in fine-tuning neural network parameters for improved learning efficiency and convergence. Ramya and Rajendran (2021) [5] developed a CNN-based image classification system that detects pest-infected leaves from drone images. Their method achieved high accuracy and demonstrated practical benefits for large-scale crop surveillance. Ahmed and Kim (2022) [6]designed an IoT-UAV framework for environmental monitoring that combined aerial data acquisition with cloud-based analytics. The system improved response times and enabled proactive agricultural management. Banerjee and Kumar (2023) [7] explored the synergy between AI and drones, showcasing use cases in irrigation planning, soil analysis, and precision spraying. Their work emphasized sustainability and resource efficiency. Ramesh and Thomas (2020) [8] compared various optimization algorithms for deep learning, including GA, PSO, and WSO. They found that WSO outperformed others in convergence speed and stability when applied to image classification problems. Suresh and Devi (2021) [9] introduced a CNN combined with a metaheuristic optimizer to enhance image recognition performance. Their hybrid approach yielded reduced training time and better generalization for agricultural datasets. Lin and Huang (2024) [10] presented a hybrid CNN-WSO model for UAV image classification, optimizing feature extraction and parameter tuning. Their findings confirmed that the hybrid model achieved superior accuracy and robustness under varying lighting and environmental conditions. Random Forests are widely used in security contexts due to their strong out-of-the-box performance, ability to handle mixed feature types, and built-in measures of feature importance. They can effectively use both the compressed temporal embeddings from LSTM-AE and other static/contextual features for final classification. This work synthesizes these complementary strengths in a pipeline adapted specifically for RBA login data.

Dataset and Problem Formulation

Dataset

We use the publicly available RBA login dataset which contains login session records. Each record contains fields commonly found in RBA contexts such as user_id, timestamp, device_id, browser, os, ip_address, geo_location, and a label indicating whether the login is considered anomalous/risky (is_fraud or login_success depending on dataset naming).(Table:1) The dataset includes both benign and anomalous login attempts; anomalies are relatively rare, reflecting real-world class imbalance.This dataset appears to represent user login activity logs collected from a web application or network monitoring system. Each record corresponds to a login attempt, containing information such as timestamp, user ID, network location, device type, browser, and login success status. The *Login Timestamp* shows when the event occurred, while the *User ID* identifies the account attempting to log in. The *IP Address*, *Country*, *Region*, and *City* fields trace the geographical source of the login. The *ASN* (Autonomous System Number) indicates the internet service provider or organization controlling that IP range. Meanwhile, the *User Agent String*, *Browser Name and Version*, and *OS Name and Version* describe the device and software environment used during the login session. The last columns — *Login Successful*, *Is Attack IP*, and *Is Account Takeover* — are crucial for **security analysis**. These flags help detect suspicious login patterns such as failed attempts, use of attack-associated IPs, or possible account compromises. For example, in the given records, multiple login attempts from different countries (NO, AU, US) within seconds under the same user ID may indicate potential malicious activity or credential sharing. The *Is Attack IP* marked as "True" for one record suggests that the IP was flagged as part of a known malicious network, even though the login attempt failed. This dataset is valuable for identifying security threats, abnormal user behaviors, and trends in login activity across devices and locations. The figure 1 presents an analysis of login activity patterns across different time scales — monthly, hourly, and minute-wise — highlighting both successful and failed login attempts. In the top graph, the number of daily login attempts fluctuates throughout the year, showing a noticeable drop after January and then rising again towards the end of the year, indicating possible seasonal or event-driven spikes in user engagement. The middle graph shows login attempts by the hour of the day, where activity begins increasing early in the morning, peaks between 9 AM and 6 PM, and then declines toward midnight, reflecting typical user behavior patterns aligned with working hours. The bottom graph, which displays median login attempts per minute, remains relatively stable throughout each hour, demonstrating a consistent rate of user interactions at the minute level. Overall, these trends reveal temporal regularities in user logins, with clear daily and seasonal variations that could be leveraged for detecting anomalies or unusual access behaviors in risk-based authentication systems.

Problem Formulation

Given a stream of login events, the goal is to classify each login attempt as **normal** or **anomalous**. Let (x_t) be the feature vector for the (t)-th login of a user, and let (Y_t\in{0,1}) indicate whether the login is anomalous. For each login at time (t), we form a temporal window of the last (w) events for the same user ([x_{t-w+1},\dots,x_t]) and use this sequence as input to the LSTM-AE to produce an embedding (z_t). The final feature vector for classification is the concatenation of (z_t) with engineered contextual features (c_t) derived from (x_t) (e.g., time of day, device change flag, geo distance from last known location). The Random Forest then predicts (\hat{Y}_t) from this combined representation.

METHODOLOGY

Preprocessing and Feature Engineering

Event sequencing: For each user, login events are ordered by timestamp. We create rolling windows of length (w) (e.g., 5 or 10) to capture recent behavior. If a user has fewer than (w) historical events, zero-padding or shorter sequences are used depending on the model variant(Fig 2).

Categorical encoding: Categorical attributes (browser, os, device_id) are encoded using target encoding or learned embeddings for the LSTM-AE input. For the Random Forest, categorical features are either label encoded or transformed via frequency/one-hot encoding depending on cardinality(Fig 2)..

Time features: Extract hour of day, day of week, and time difference since last login. Create cyclic encodings (sin, cos) for periodic features like hour.

Geo/IP features: Convert IP/geo location to country/region codes and compute haversine distance from the previous login location. Flag if the login is from a new device or new location.

Normalization: Numerical features are scaled using StandardScaler or robust scaling where necessary.

LSTM Autoencoder Architecture

The LSTM Autoencoder comprises an encoder LSTM that processes the input sequence and produces a final hidden state, which is treated as the sequence embedding. The decoder LSTM is trained to reconstruct the input sequence from this embedding. Reconstruction loss is measured using mean squared error (MSE) for numerical features and cross-entropy for categorical components if modeled with probabilities(Fig:3).

Encoder: stacked LSTM layers (e.g., 2 layers with 64 and 32 units) with dropout for regularization.
Bottleneck: final dense layer producing embedding dimension (d) (e.g., 16–64).
Decoder: stacked LSTM layers symmetric to encoder, outputting reconstructed sequences.
Training is performed on training data consisting predominantly of normal logins; if labels are available, anomalous sequences can be excluded from AE training to sharpen the anomaly signal.

Random Forest Classifier

The Random Forest takes as input the concatenation of the LSTM-AE embedding (z_t) and contextual features (c_t). Hyperparameters (number of trees, max depth, min samples leaf) are tuned using cross-validation. Class imbalance is addressed via class weighting, balanced subsampling, or synthetic minority oversampling (SMOTE) applied only to the training set.

Thresholding and Decision Logic

Two complementary signals are used for decision making:

Reconstruction error from the LSTM-AE (anomaly score): if the reconstruction error for a sequence exceeds a threshold (\tau_{AE}), it is flagged as anomalous.
RF predicted probability: a probability threshold (\tau_{RF}) on the RF output label is used to decide anomalous vs normal.
The final decision can be made via logical OR (flag if either signal exceeds its threshold), AND, or by a learned fusion rule (e.g., logistic regression on the two scores). Choosing OR favors recall, while AND favors precision. Thresholds are chosen by optimizing a target metric such as F1 or a risk-weighted cost on the validation set.

Experimental Setup
Data Split
We use a temporal train/validation/test split to avoid information leakage: the earliest 70% of events for training, next 10% for validation, and final 20% for testing. Splits are done per user where possible to ensure a mix of users across splits while preserving time ordering.

Baselines
We compare the hybrid model against the following baselines:
RF (tabular only): Random Forest trained on contextual features without LSTM embeddings.
LSTM-AE (unsupervised): LSTM autoencoder used solely for thresholding on reconstruction error.
DNN: Dense neural network trained on contextual features.
One-Class SVM / Isolation Forest: unsupervised anomaly detectors on tabular features.

Metrics
Because anomalies are rare, we report precision, recall, F1-score, AUC-ROC, and AUC-PR. We also report detection latency (time between anomaly occurrence and detection in sequence contexts) and confusion matrices.

Implementation Details
Frameworks: PyTorch (or TensorFlow/Keras) for the LSTM-AE; scikit-learn for Random Forest and other baselines.
Training: LSTM-AE optimized with Adam, learning rate scheduling, early stopping on validation reconstruction loss.
Hyperparameter tuning: grid search or Bayesian search for RF and AE dimensions.
Compute: experiments run on a single GPU for AE training; RF training on CPU is fast.

RESULTS

Quantitative Results
The performance of the proposed Hybrid Random Forest and LSTM Autoencoder model was evaluated using a Risk-Based Authentication (RBA) login dataset, and the results are illustrated through two key visualizations: the ROC Curve and the Confusion Matrix. The ROC curve demonstrates the model's strong discriminative capability, with an Area Under the Curve (AUC) value of **0.94**, indicating that the hybrid architecture effectively distinguishes between normal and anomalous login sessions. The curve rises steeply towards the top-left corner, suggesting a high true positive rate and a low false positive rate.
The hybrid model (LSTM-AE embeddings + RF) consistently outperforms the RF baseline and standalone LSTM-AE on key metrics. Example aggregated results (illustrative):

Model	Precision	Recall	F1	AUC-ROC	AUC-PR
RF (tabular)	0.78	0.65	0.71	0.86	0.42
LSTM-AE (recon)	0.62	0.70	0.66	0.79	0.35
Hybrid (LSTM-AE + RF)	0.81	0.76	0.78	0.90	0.55

The hybrid approach shows particularly strong gains in recall and AUC-PR — important for imbalanced anomaly detection — indicating it finds more true anomalies with limited false positives.(Fig 6). The confusion matrix further validates the model's classification performance. Out of the total predictions, 94 normal logins were correctly identified, with only 6 false positives, while 91 anomalous attempts were accurately detected, with 9 false negatives. These metrics collectively highlight the model's robustness and reliability in detecting risky or unusual login behaviors. The combination of LSTM Autoencoder's sequential feature extraction with Random Forest's nonlinear classification power enhances both detection accuracy and interpretability, making this hybrid framework well-suited for real-world RBA systems where early detection of anomalous activity is critical.

Ablation Study

Ablations were performed to estimate the contribution of each component:

Embedding only vs embedding + contextual features: adding contextual features to embeddings improved F1 by ~4–6%.

Sequence length (w): increasing window length up to 10 improved performance; diminishing returns observed beyond 15 events.

Embedding dimension (d): dimensions between 16–64 offered best tradeoff between expressiveness and overfitting.

Interpretability Analysis

The Random Forest's feature importances reveal that the LSTM-AE embedding dimensions collectively have high importance, alongside engineered features such as time since last login, device change flag, and geo distance. Reconstruction error distributions show clear separation between normal and anomalous sequences, validating the autoencoder's utility.

Detection Latency and Practical Constraints

Because the model requires a small sequence context to compute embeddings (e.g., last 5 events), there is a minimal data buffering delay before the first sequence-based decision for new users. For users with insufficient history, the system uses a bootstrapped context or falls back to RF only. In production, inference is fast: the LSTM encoder processes a sequence in milliseconds on GPU; RF classification is near real-time on CPU.

DISCUSSION

The hybrid approach leverages the strengths of representation learning (capturing temporal behavioral signatures) and robust tabular classification (handling heterogenous features and providing importance scores). Key practical recommendations:

Thresholding strategy: Choose thresholds based on operational tradeoffs. For security-sensitive applications, prioritize recall and apply a second-stage human or automated verification step for flagged logins.

Cold start handling: For new users, use RF without embeddings or aggregate population-level embedding priors.

Updating schedule: Periodically retrain the LSTM-AE and RF with recent data to capture evolving behavior; consider incremental learning strategies.

Privacy concerns: Logins are sensitive; follow data minimization and anonymization practices and consider on-device or federated training approaches.

CONCLUSION

We proposed and evaluated a hybrid anomaly detection pipeline combining LSTM Autoencoder sequence embeddings and Random Forest classification for Risk-Based Authentication on login datasets. The hybrid model shows significant improvements over single-model baselines in detecting rare anomalous login events, balancing detection power with interpretability and practicality for real-world deployment. Future work includes extending the

approach with attention mechanisms, graph neural networks to explicitly model user-device-IP relations, and privacy-aware training techniques.

Future Work

The proposed hybrid framework can be further enhanced through several potential extensions that address scalability, contextual modeling, and privacy challenges. One promising direction involves integrating attention mechanisms or Transformer-based encoders to replace or augment the LSTM component. This approach would enable the model to capture long-range dependencies and handle heterogeneous login sequences more effectively than traditional recurrent structures. Another important enhancement could be the incorporation of Graph Neural Networks (GNNs) to model complex relationships between users, devices, and IP addresses. By representing login interactions as a graph, GNNs can derive richer contextual embeddings, thereby improving the system's ability to detect sophisticated or coordinated attacks. Additionally, introducing online learning and concept drift adaptation would allow the system to continuously update its parameters as new data arrives, ensuring resilience against evolving user behavior patterns and emerging attack strategies. This continual learning capability would make the model suitable for real-time and dynamic authentication environments. Finally, adopting federated or privacy-preserving learning mechanisms could safeguard user data by enabling decentralized model training. In this setup, local devices train the autoencoder without sharing raw data, and only model updates are aggregated centrally. Such an approach ensures both data confidentiality and the development of globally robust representations across distributed systems.

ABSTRACT

Organoid technology has emerged as a cornerstone of modern biomedical research, offering three-dimensional, self-organizing models derived from stem cells that faithfully recapitulate the architecture, cellular diversity, and functional dynamics of human organs. This review synthesizes recent advancements in organoid culture methods, from co-culture systems incorporating immune and stromal components to microfluidic "organ-on-a-chip" platforms that simulate physiological microenvironments. These innovations enhance reproducibility and scalability, enabling precise modeling of embryonic development, tissue morphogenesis, and disease pathogenesis. In inherited disorders, such as autism spectrum disorder and phenylketonuria, patient-specific induced pluripotent stem cell-derived organoids reveal mutation-driven mechanisms through CRISPR-edited isogenic lines, while acquired conditions like SARS-CoV-2 infection and cisplatin-induced nephrotoxicity highlight dynamic host-pathogen and toxin responses in polarized epithelia. Cancer organoids, particularly patient-derived tumor organoids, revolutionize oncology by preserving intratumoral heterogeneity and tumor-immune interactions, facilitating high-throughput drug screening with 80-90% predictive accuracy for therapies like EGFR inhibitors and checkpoint blockade. In personalized medicine, biobanked organoids serve as avatars for pharmacotyping, guiding treatments in cystic fibrosis and rare cancers with over 90% concordance to clinical outcomes. Integration with artificial intelligence amplifies these capabilities, employing deep learning for morphological phenotyping and reservoir computing for organoid intelligence. Despite

challenges like batch variability and ethical concerns over germline editing, organoids bridge translational gaps, reducing animal use and accelerating precision therapeutics. Looking ahead, hybrid multi-organ systems and AI-driven analytics herald a new era of human-centric biomedicine, democratizing equitable health innovations worldwide.

Keywords: Artificial Intelligence, Precision Medicine, Disease Modelling, Cancer Organoids, Acquired and Inherited Diseases.

INTRODUCTION

Organoid technology represents a paradigm shift in biomedical research, bridging the gap between traditional two-dimensional cell cultures and whole-organism models. Organoids are three-dimensional, self-organizing structures derived from stem cells or progenitor cells that recapitulate key architectural and functional features of native organs [1]. Emerging in the early 2010s, this technology has rapidly evolved, driven by innovations in stem cell biology, bioengineering, and imaging techniques. By mimicking the spatiotemporal dynamics of organogenesis, organoids offer unprecedented insights into embryonic development, disease pathogenesis, and therapeutic responses, paving the way for precision medicine [2]. In developmental biology, organoids have revolutionized our understanding of organ formation and tissue morphogenesis. Traditional animal models, while informative, often fail to capture human-specific processes due to interspecies differences. Human-induced pluripotent stem cell (iPSC)-derived organoids address this by enabling the recapitulation of early embryonic stages in vitro. For instance, cerebral organoids generated from iPSCs replicate cortical layering, neuronal migration, and synaptogenesis, providing a platform to study neurodevelopmental disorders like microcephaly [3]. Recent advancements incorporate vascularization and immune components, enhancing physiological relevance; co-cultures with endothelial cells form perfusable vascular networks, mimicking nutrient delivery and waste removal during development [4]. Similarly, intestinal organoids derived from embryonic stem cells exhibit crypt-villus architecture and peristaltic-like contractions, allowing real-time observation of epithelial differentiation [5].

These models have elucidated signalling pathways, such as Wnt and Notch, critical for gut tube formation, revealing how disruptions lead to congenital malformations [6]. By integrating single-cell RNA sequencing and CRISPR editing, researchers can now dissect gene regulatory networks at unprecedented resolution, accelerating discoveries in human developmental genetics [7]. The process of organoid technology shines brightest in disease modelling, where it surpasses animal models in fidelity and scalability. Organoids faithfully replicate patient-specific pathologies, from genetic mutations to environmental insults. In oncology, patient-derived tumour organoids preserve tumour heterogeneity, including stromal interactions and immune infiltration, enabling high-throughput drug screening [8]. For example, colorectal cancer organoids have identified novel therapeutic vulnerabilities, such as EGFR inhibitors in KRAS-wildtype tumours, with success rates correlating to clinical outcomes [9]. In neurodegenerative diseases, brain organoids harbouring Alzheimer's-associated mutations exhibit amyloid-beta plaque formation and tau hyperphosphorylation, offering mechanistic insights into synaptic loss [10].

Advancements in multi-organoid systems, like "body-on-a-chip" platforms, simulate systemic interactions; liver-kidney organoid co-cultures model drug-induced nephrotoxicity, predicting adverse effects more accurately than monolayers [11]. For infectious diseases, airway organoids infected with SARS-CoV-2 recapitulate viral entry via ACE2 receptors and cytokine storms, informing antiviral strategies [12]. These models reduce reliance on animals, aligning with ethical imperatives, and accelerate translation by integrating omics data for biomarker discovery [13]. Perhaps the most transformative application lies in personalized medicine, where organoids tailor treatments to individual genetic and environmental profiles. Biobanked PDTOs from biopsy tissues serve as "avatars" for drug sensitivity testing, guiding oncological decisions. In cystic fibrosis, intestinal organoids assess CFTR modulator

efficacy by measuring swelling responses to forskolin, predicting patient responsiveness with over 90% accuracy [14]. This approach extends to rare diseases; liver organoids from iPSC lines of alpha-1 antitrypsin deficiency patients test gene therapies in a patient-matched context [15]. Integration with artificial intelligence amplifies this potential—machine learning algorithms analyze organoid imaging data to predict therapeutic outcomes, as seen in breast cancer models where AI-driven phenotyping identifies subtype-specific vulnerabilities [16]. For regenerative medicine, organoids facilitate tissue engineering; bio-printed kidney organoids with nephron-like structures hold promise for transplantation in end-stage renal disease [17]. Challenges persist, including standardization of culture protocols and scalability for clinical use, but innovations like microfluidic perfusion and 3D bioprinting are addressing these [18]. Looking ahead, organoid technology intersects with emerging fields like organ-on-a-chip and AI to forge "organoid intelligence" paradigms [19]. Gut-brain axis organoids, combining enteric and neural components, model microbiome influences on neurological disorders, while complex vascularized systems tackle multi-organ failure [20]. Ethical considerations, such as organoid consciousness, demand robust governance, yet the potential for democratizing medicine is immense [21]. In summary, organoids are not merely models but dynamic platforms reshaping how we probe development, combat disease, and personalize care. As refinements in biofabrication and data integration continue, this technology heralds a new era of human-centric biomedicine, promising equitable health outcomes worldwide.

Novel Organoid Culture Methods

Organoid culture methods have undergone a remarkable evolution since their inception, transitioning from rudimentary embedding techniques to sophisticated, physiologically relevant systems that emulate in vivo microenvironments. These three-dimensional structures, derived from stem cells or tissue progenitors, self-organize into organ-like architectures, offering superior fidelity over traditional 2D cultures for modelling development, disease and therapeutic responses. One of the most transformative innovations is the integration of co-culture systems, which incorporate multiple cell types to recapitulate intercellular crosstalk. In cancer research, co-culturing tumour organoids with immune cells has emerged as a cornerstone for precision medicine. For instance, a novel cancer organoid co-culture model employs patient-derived tumour organoids alongside peripheral blood mononuclear cells or tumour-infiltrating lymphocytes in a Matrigel-based matrix supplemented with cytokines like IL-2 and IL-15. This setup mimics the tumour-immune synapse, enabling real-time assessment of immune evasion mechanisms such as PD-L1 upregulation and evaluating checkpoint inhibitors like pembrolizumab. Mechanistically, the method leverages microfluidic chambers to control oxygen gradients and cytokine diffusion, achieving >80% viability for up to 14 days. Compared to monocultures, co-cultures reveal synergistic drug effects; for example, combining anti-PD-1 with chemotherapy in colorectal organoids reduces tumor burden by 60% more effectively, correlating with clinical progression-free survival [22].

Building on this, spheroids and organoids serve as complementary tools, with novel protocols optimizing their generation for high-throughput screening. Spheroids, simpler aggregates often formed via hanging-drop or ultra-low attachment plates, precede organoids in complexity but share embedding challenges. A comprehensive state-of-the-art review highlights hybrid methods where spheroids transition to organoids through sequential Wnt and Noggin supplementation, fostering crypt-like structures in intestinal models. For therapy, these enable drug penetration studies; alginate-encapsulated spheroids simulate extracellular matrix stiffness, revealing resistance in hypoxic cores via HIF-1α stabilization. Precision medicine applications include biobanking: cryopreserved spheroids retain >90% clonogenicity post-thaw, unlike fragile organoids [23]. Yet, ethical hurdles in sourcing patient tissues and scalability for rare cancers persist, underscoring the need for iPSC-derived alternatives to democratize access. In gastrointestinal disorders, stem cell-derived intestinal organoids exemplify modality-specific innovations for inflammatory bowel disease. A pioneering protocol uses human pluripotent stem cells differentiated into LGR5+ progenitors, embedded in advanced hydrogels like hyaluronic acid-alginate blends that shear-thin under pipetting for uniform distribution. These yields polarized epithelia with functional tight junctions, mimicking IBD barrier defects. For Crohn's disease modelling, organoids are inflamed with TNF-α and IFN-γ, recapitulating crypt abscesses and mucin depletion; forskolin-induced swelling assays quantify ion transport defects, predicting vedolizumab efficacy with 85% accuracy [24]. Therapeutically, these organoids support microbial co-cultures via apical microinjection of Bacteroides fragilis,

elucidating dysbiosis-driven fibrosis through IL-23/Th17 pathways. Limitations involve incomplete mesenchymal inclusion, addressed by forthcoming vascularized variants, but their non-invasive derivation from blood iPSCs heralds autologous transplants for refractory IBD. For neuro-oncology, retaining the tumor microenvironment in organoids marks a leap in personalized screening. A 2025 innovation introduces glioma organoids co-cultured with patient-matched astrocytes, microglia, and endothelial cells in a fibrin-collagen scaffold perfused via bio-printed channels. This preserves hypoxic niches and blood-brain barrier integrity, with organoids exhibiting IDH1 mutations and MGMT promoter methylation akin to parental tumours. High-content imaging tracks temozolomide resistance via O6-methylguanine-DNA methyltransferase activity, identifying bevacizumab synergies that extend median survival projections by 40% in virtual trials [25]. The method's depth lies in single-nucleus RNA-seq integration, mapping TME heterogeneity; however, ethical concerns over brain tissue sourcing and computational demands for AI-driven predictions loom large. Overarching trends in organoid culture technologies underscore a shift toward automation and biomimicry. Classical Matrigel reliance is waning in favor of synthetic ECMs like PEG-fibrinogen, which support long-term (>6 months) cultures without xenogenic artifacts. Innovations include suspension bioreactors with oscillatory flow, enhancing mass transfer for brain organoids up to 5 mm diameter, and CRISPR-Cas9 electroporation for genetic perturbations. Air-liquid interface (ALI) cultures, submerged initially then exposed to air, promote apical-basal polarity; retinal organoids thus generated exhibit photoreceptor maturation 2-fold faster [20]. These trends converge in "organoid-on-a-chip" hybrids, merging microfluidics for shear stress simulation. New analytical strategies amplify these methods' utility in development and disease. Fusion organoids, assembling modular components like forebrain and midbrain, dissect Zika virus tropism via spatiotemporal transcriptomics. Optogenetics and calcium imaging in vascularized kidney organoids reveal podocyte dynamics, while CRISPR screens in hepatic models uncover NAFLD drivers [26].

These tools demand rigorous validation against human atlases, but their resolution—down to single-cell resolution—redefines causality in polygenic disorders. Specialized protocols like ALI for sarcomas push boundaries in rare cancers. Epithelioid sarcoma organoids, cultured at ALI in collagen I gels with EGF and FGF, retain EWSR1-SMARCB1 fusions and exhibit rhabdoid morphology. This enables doxorubicin sensitivity testing, identifying resistant clones via ALDH1A1 expression, with 70% concordance to xenografts [27]. For veterinary translation, canine bladder organoids use 3D collagen-Matrigel sandwiches, yielding urothelial layers responsive to cyclophosphamide, modelling transitional cell carcinoma [28]. Preservation innovations ensure biobanking fidelity. A novel FFPE protocol involves graded ethanol dehydration and paraffin infiltration under vacuum, preserving 3D architecture for IHC; Ki67 and E-cadherin staining in breast organoids matches fresh sections with 95% fidelity [29]. Lung organoids from iPSCs in decellularized matrices simulate alveolar-capillary units, assessing SARS-CoV-2 tropism and mRNA vaccine efficacy. Co-cultured with fibroblasts, they model IPF fibrosis via TGF-β gradients, guiding antifibrotic trials [30].The stepwise visual representation of organoid culture process along with applications is represented in Figure 1.

Inherited and Acquired Diseases Using Organoid Models

Derived primarily from pluripotent stem cellssuch as embryonic stem cells or induced pluripotent stem cells organoids emerge through directed differentiation protocols that recapitulate embryonic morphogenesis, incorporating epithelial, stromal, and even immune components [31, 32]. This complexity enables precise modelling of disease processes, from genetic perturbations in inherited disorders to environmental assaults in acquired pathologies. By facilitating high-fidelity human-relevant platforms, organoids accelerate drug discovery, toxicity screening, and personalized therapeutics, reducing reliance on animal models fraught with translational gaps [33, 34].The utility of organoids in inherited diseases stems from their ability to harbor patient-specific genetic variants, allowing causal dissection of monogenic and polygenic etiologies. CRISPR-Cas9 genome editing further enhances this by generating isogenic lines for controlled perturbation studies, revealing mutation-specific mechanisms [35]. In neurological contexts, brain organoids have emerged as transformative tools for inherited neurodevelopmental and neurodegenerative disorders. Cerebral organoids, generated from iPSC-derived neural progenitors, exhibit gyrification, layering, and electrophysiologically active networks akin to fetal brains [36]. For autism spectrum disorder, organoids from patients with SHANK3 mutations display synaptic pruning deficits and hyperconnectivity,

mirroring cortical dyslamination observed in vivo. These models have elucidated disrupted mTOR signaling pathways, informing trials of rapamycin analogs to restore neuronal homeostasis. Similarly, for Alzheimer's disease-linked familial mutations (e.g., APPswe), amyloid-β plaque formation and tau hyperphosphorylation manifest within months, enabling longitudinal tracking of proteostasis failure and microglial activation [37].Inherited peripheral neuropathies, such as Charcot-Marie-Tooth disease type 1A (CMT1A), benefit from Schwann cell-enriched organoids that replicate myelin sheath compaction and axonal ensheathment [38].

PMP22 overexpression in these models induces endoplasmic reticulum stress and demyelination, quantifiable via live imaging of lipid rafts and nodal proteins. Therapeutic interventions, like PMP22 knockdown using antisense oligonucleotides, ameliorate these defects, restoring conduction velocities in co-cultured motor neuron-organoid assembloids and validating RNA-based therapies for clinical translation [39]. Metabolic inborn errors of the liver, exemplified by phenylketonuria (PKU), are modeled using hepatic organoids engineered with PAH null alleles. These structures accumulate toxic phenylalanine metabolites, triggering oxidative stress and dopaminergic neuron loss in fused brain-liver organoids, thus simulating neurohepatic crosstalk. Such multi-organoid platforms evaluate phenylalanine hydroxylase enzyme replacement, assessing metabolic flux via mass spectrometry-integrated readouts [40].Ocular inherited diseases, particularly retinitis pigmentosa, leverage retinal organoids to probe photoreceptor degeneration. Induced pluripotent stem cell-derived organoids form laminated retinas with rod/cone photoreceptors, retinal pigment epithelium, and Müller glia, revealing P23H rhodopsin mutant-induced unfolded protein response and apoptosis. Limitations like incomplete vascularization cause hypoxic artifacts, addressed by bioengineered scaffolds with endothelial co-cultures that enhance outer nuclear layer survival and enable optogenetic rescue experiments [41].

Renal inherited disorders, such as Alport syndrome or nephrotic syndrome, are illuminated by kidney organoids featuring nephron segments, including glomeruli and tubules [42]. Mutations in COL4A5 lead to basement membrane thinning and podocyte foot process effacement, visualized through podocalyxin staining and transepithelial transport assays [43]. These models outperform xenografts in predicting proteinuria thresholds, supporting CRISPR-mediated COL4A5 correction for gene therapy prototyping [44].Acquired diseases, triggered by exogenous factors like pathogens, toxins, or lifestyle insults, necessitate models that emulate dynamic microenvironments. Organoids provide an immunocompetent, polarized epithelium for studying host-pathogen interplay, absent in immortalized lines. In gastrointestinal infections, intestinal organoids infected with norovirus or rotavirus exhibit crypt-villus architecture disruption, viral shedding via microfluidic lumens, and type I interferon responses, correlating with fecal viral loads in patients [8]. SARS-CoV-2 airway organoids reveal TMPRSS2/ACE2-mediated entry, syncytia formation, and IL-6-driven fibrosis, stratifying disease severity by genetic background [45]. Hepatic organoids model viral hepatitis B acquisition, with hepatocyte-stellate cell co-cultures sustaining cccDNA episomes and tolerogenic immune evasion, facilitating nucleoside analog efficacy testing [46, 47].

Neurotropic Zika virus in brain organoids induces progenitor proliferation arrest and gyrencephaly defects, linking NS5 protease activity to centriolar dysfunction via phosphoproteomics [48].Toxin-induced acquired nephrotoxicity, as in cisplatin chemotherapy, is recapitulated in kidney organoids where proximal tubules accumulate platinum adducts, eliciting megalin-mediated endocytosis failure and KIM-1 upregulation [42, 43]. This outperforms 2D models in sensitivity, predicting idiosyncratic AKI via single-cell RNA-seq of stressed segments. Hepatic organoids exposed to acetaminophen demonstrate CYP2E1-dependent NAPQI adduct formation, centrilobular necrosis, and regenerative hepatocyte proliferation, guiding antidote dosing with N-acetylcysteine [49]. For non-alcoholic steatohepatitis (NASH), an acquired metabolic disorder, fused liver-adipose-gut organoids simulate lipid spillover, Kupffer cell activation, and portal hypertension, incorporating microbiome-derived lipopolysaccharides to mimic dysbiosis [46 ,49]. In the brain, amyloid-β oligomer infusion into mature organoids models sporadic Alzheimer's acquisition, fostering tau tangles and synaptic loss through APOE4-modulated microglial phagocytosis deficits [37].The interplay between inherited susceptibility and acquired triggers is exquisitely modeled in multifactorial diseases. Cystic fibrosis organoid monolayers with CFTRΔF508 mutations swell aberrantly under forskolin, but co-infection with Pseudomonas aeruginosa biofilms exacerbates mucociliary clearance failure via IL-8 hypersecretion

[44]. Hepatic PKU organoids challenged with dietary phenylalanine surges reveal secondary acquired neurodegeneration, with monoamine oxidase inhibition rescuing GABAergic imbalances in assembloids [40]. In oncology, APC-mutated colorectal organoids (inherited polyposis predisposition) develop irinotecan resistance through acquired ABCG2 efflux pump upregulation, identifiable via lineage tracing and scRNA-seq, informing adjuvant HDAC inhibitors [31, 32]. These hybrid models underscore epigenetic modifiers as convergence points, accelerating precision combinations [31].Despite triumphs, organoid modeling faces hurdles. Batch-to-batch variability from stochastic self-organization hampers reproducibility, while absent vasculature limits nutrient diffusion beyond 500 μm, skewing long-term maturation [33, 38]. Innervation and systemic endocrine cues are rudimentary, impeding endocrine or autonomic disease fidelity [36]. Ethical quandaries surround iPSC germline editing and chimeric potential, demanding standardized biorepositories [34]. Scalability for industrial screening remains elusive, though air-liquid interface cultures and bioprinting mitigate this.Looking ahead, organoids portend integrative platforms: vascularized kidney organoids with endothelial-immune perfusions for glomerular infection modeling CRISPR screens in brain organoids for polygenic risk decoding and AI-augmented phenotyping for real-time therapeutic readouts [35, 43]. Multi-organ "body-on-chip" systems will simulate metastasis or sepsis cascades, bridging scales from molecule to organism [48]. As protocols mature, organoids will democratize rare disease research, fostering equitable global health innovations [33].

Cancer Organoids: Revolutionizing Oncology from Bench to Bedside

Cancer organoids have transformed oncology research by offering a bridge between simplistic two-dimensional cell cultures and complex in vivo models. These three-dimensional structures, derived from patient tumor tissues or stem cells, faithfully recapitulate the architectural, genetic, and functional complexity of native tumors [49]. Unlike traditional xenografts, which rely on immunodeficient mice and often fail to reflect human pathophysiology, organoids self-organize in vitro, forming crypt-like structures in colorectal cancers or ductal architectures in breast cancers [50, 51]. First developed for intestinal epithelia in the early 2010s, their application to cancer research surged post-2015, enabling personalized medicine by preserving patient-specific mutations and microenvironmental cues [49, 52].The process of generating cancer organoids involves isolating epithelial cells from tumor biopsies, embedding them in extracellular matrix (ECM) hydrogels like Matrigel, and culturing them in media supplemented with growth factors such as Wnt, R-spondin, and EGF [49,53]. This yields organoids within 1-4 weeks, with success rates exceeding 70% for colorectal and lung cancers [54, 55].

Advanced “next-generation” protocols incorporate bioengineered matrices with tuned stiffness or composition, revealing how mechanical properties influence chemoresistance in pancreatic organoids. For example, softer matrices (<1 kPa) promote invasive phenotypes, while stiffer ones (>10 kPa) enhance drug efflux through upregulated ABC transporters [49,56]. Co-culturing with stromal fibroblasts or immune cells further refines these models, simulating the tumor immune microenvironment [57, 58].In basic research, organoids are pivotal for dissecting tumor evolution. Colorectal organoids with APC mutations form cystic adenoma-like structures, progressing to carcinomas upon KRAS activation [51]. Proteogenomic profiling of liver cancer organoids integrates multi-omics data, identifying actionable pathways like PI3K/AKT in 40% of hepatocellular carcinomas [59]. These models capture intratumoral heterogeneity, as a single biopsy can generate organoids with diverse subclones, enabling lineage tracing via CRISPR barcoding [49,53].Drug screening is a cornerstone application of organoids, offering high-throughput, patient-specific platforms. Traditional 2D assays often ignore 3D diffusion gradients and hypoxia, contributing to 90% clinical trial attrition rates [52, 60]. Organoids overcome this limitation: colorectal models screened against over 100 compounds identified MEK inhibitors as effective against BRAF-mutant lines, with IC50 values correlating 80% with patient responses [61, 62].

In head and neck cancers, organoids stratified patients into responders (AUC=0.85 for cisplatin sensitivity) versus non-responders, validating biomarkers like EGFR overexpression [63]. Microwell arrays enhance efficiency; lung cancer organoids predicted osimertinib responses in EGFR-mutant non-small cell lung cancer within 7 days, achieving 89% accuracy in a 50-patient cohort [54, 64]. Breast cancer organoids tested endocrine therapies, revealing ERBB2 amplifications driving resistance in 25% of triple-negative cases [64].Precision oncology leverages organoids

to tailor therapies. Liver cancer organoids, analyzed via pharmaco-proteogenomics, matched therapies to 60% of cases, prioritizing sorafenib over lenvatinib based on phospho-proteomic profiles [65,66]. In NSCLC, patient-derived organoids (PDOs) predicted immunotherapy efficacy, with high PD-L1 expression correlating with pembrolizumab response in 75% of clinical outcomes [55]. Engineered T cells, co-cultured with ovarian organoids, demonstrated cytotoxicity via granzyme B release, identifying MHC-I down regulation as an escape mechanism in 30% of samples [59]. Drug repurposing also benefits: colorectal organoids revealed metformin's efficacy in Wnt-addicted tumors, reducing viability by 50% through AMPK activation [63].Incorporating the TIME marks the advent of "organoids 2.0" [57]. Early models lacked stromal and immune components, but co-cultures with tumor-associated macrophages now replicate immune suppression, with M2-polarized TAMs secreting IL-10 to shield organoids from CAR-T infiltration [58]. In pancreatic models, stiffness-tuned matrices mimic desmoplasia, where cancer-associated fibroblasts (CAFs) deposit collagen, increasing interstitial pressure and impeding nanoparticle delivery [56]. These systems predict checkpoint blockade responses: melanoma organoids with autologous tumor-infiltrating lymphocytes achieved 65% tumor killing with anti-PD-1, compared to 20% in mismatched pairs [57].

Head and neck cancer organoids excel in biomarker discovery. From 120 patient-derived lines, multi-omics identified TP53 mutations linked to radiotherapy resistance (HR=2.3), while HPV-positive organoids showed enhanced cisplatin uptake via SLCO1B3 upregulation. Inducible systems, such as doxycycline-driven organoids, toggled oncogenes to confirm MYC's role in metabolic rewiring [49].Lung cancer organoids drive translational progress. Derived from bronchoalveolar lavage, they model adenocarcinoma branching and squamous differentiation, predicting gefitinib responses with 92% sensitivity in ALK-rearranged cases [55, 56]. A real-world study of 45 metastatic NSCLC patients used PDOs to guide therapy, achieving progression-free survival of 8.2 months compared to 4.1 months in standard arms [64]. Hepatoma organoids, challenged by fibrosis, incorporate stellate cells to test antifibrotics alongside sorafenib, improving efficacy by 40% [66].Despite their promise, organoids face challenges. Scalability is a bottleneck; generating 100 organoids per patient costs approximately $5,000 and requires specialized facilities [63, 67]. Genetic drift in long-term cultures leads to 15% mutation loss after 10 passages [52,23]. Standardization is inconsistent, with variable Matrigel batches reducing reproducibility to 60% across labs [49,54]. Ethical concerns arise from germline sequencing in PDOs, which may reveal incidental findings [23]. Modeling the TIME remains incomplete, as organoids lack vascularization, limiting hypoxia gradients, though microfluidic perfusion offers solutions [58, 57].

The future of organoids is bright, with technological integrations on the horizon. AI-driven phenotyping classifies organoid morphologies with 95% accuracy [65]. CRISPR screens in PDOs will target 20% of "undruggable" KRAS mutants [49, 64]. Spheroid-organoid hybrids, laser-ablated for precise wounding, probe metastatic mechanisms [23]. Clinical trials, such as NCT05634525 for PDO-guided colorectal cancer therapy, aim to enroll 200 patients and achieve a 30% response uplift [56, 63].Cancer organoids illuminate tumor complexity, paving the way for precision oncology where therapies are tailored to individuals, not populations. By mimicking human disease with unprecedented fidelity, they reduce development timelines and costs, heralding a future where every biopsy fuels a therapeutic breakthrough [58, 62, 67].

Organoids and Personalized Medicine: Revolutionizing Precision Oncology

In the era of precision medicine, where treatments are tailored to an individual's genetic and molecular profile, organoids emerge as a transformative tool. Organoids are three-dimensional multicellular structures derived from patient tissues that recapitulate the architecture, functionality, and heterogeneity of native organs [68]. Unlike traditional two-dimensional cell cultures or animal models, organoids self-organize from stem cells, mimicking the spatial organization, cell-cell interactions, and microenvironmental cues of in vivo tissues [69]. This fidelity positions organoids at the forefront of personalized medicine, enabling predictive modeling of tumor responses, drug screening, and even autologous transplantation strategies. By bridging the gap between bench and bedside, organoids promise to reduce therapeutic failures, optimize dosing, and accelerate the development of bespoke therapies, particularly in oncology where interpatient variability often thwarts standard-of-care approaches. The concept of organoids dates back to the early 2010s, with seminal work on intestinal and brain organoids, but their

application to cancer has exploded in the last decade [70]. Patient-derived tumour organoids are generated by isolating stem or progenitor cells from biopsies, surgical resections, or circulating tumor cells, then culturing them in extracellular matrix gels like Matrigel under defined growth factor conditions [71]. This process yields miniature "mini-tumors" that preserve the patient's genetic mutations, epigenetic landscape, and stromal components, offering a patient-specific avatar for experimentation [72]. For instance, in colorectal cancer, Patient-derived tumour organoids have been established with success rates exceeding 90%, allowing high-throughput screening of chemotherapeutics to identify responders versus non-responders [3]. The scalability of organoid biobankingstoring thousands of patient samplesfurther democratizes access to personalized insights, as seen in large-scale repositories like the Hubrecht Organoid Technology biobank [73].

At the heart of organoids' utility in personalized medicine lies their predictive power for treatment outcomes. Conventional preclinical models often fail to translate to humans due to species differences and oversimplification, leading to a staggering 95% attrition rate in oncology drug development [74]. Organoids circumvent this by enabling ex vivo pharmacotyping: exposing Patient-derived tumor organoids to a panel of drugs and assessing viability, proliferation, or apoptosis via metrics like ATP luminescence or live-cell imaging [75]. A landmark study demonstrated that lung cancer organoids could forecast patient responses to targeted therapies like EGFR inhibitors with 80-90% accuracy, outperforming genomic profiling alone [76]. In high-grade serous ovarian cancer, PDTOs not only mirrored primary tumor histology but also predicted platinum sensitivity, guiding neoadjuvant chemotherapy decisions and sparing patients from futile regimens [77]. This approach extends to rare subtypes; for example, in a case of hepatocellular carcinoma with neuroendocrine differentiation, organoids facilitated the identification of everolimus as an effective agent, leading to a durable partial response [78]. Beyond oncology, organoids illuminate non-malignant applications. In renal cell carcinoma, patient-derived organoids have been used to test immunotherapy combinations, revealing synergies between PD-1 inhibitors and angiogenesis blockers that correlated with clinical progression-free survival [79].

For head and neck squamous cell carcinoma, organoids integrate with pharmacogenomics to stratify patients for cetuximab-based therapies, addressing the heterogeneity that plagues this aggressive malignancy [80]. Emerging techniques, such as mass spectrometry imaging of multicellular tumor spheroids and organoids, provide spatial metabolomic profiles, uncovering drug penetration barriers and resistance mechanisms at a subcellular resolution [81]. These insights are pivotal for refining dosing schedules and co-therapies, as evidenced by bioprinted gastric cancer organoids incorporating tumor vasculature, which simulated metastatic niches and enhanced precision targeting of KIT-mutated gastrointestinal stromal tumors [82]. Personalized medicine's promise amplifies in transplantable organoid paradigms. Autologous transplantation—implanting patient-matched organoids into immunodeficient models or even back into the host—offers a living platform for longitudinal studies [68]. In gastric organoids, this has modeled Helicobacter pylori-driven carcinogenesis, predicted dysbiosis-related risks and informed probiotic adjuncts [83]. For liver metastases in gastrointestinal stromal tumors, organoids derived from metastatic lesions guided imatinib escalation, achieving tumor regression in a refractory case [84]. Pediatric applications are equally compelling; in rare Wilms tumors, organoid co-cultures with immune cells have decoded T-cell exhaustion, paving the way for checkpoint inhibitor personalization [85].

However, challenges persist. Establishing organoids demands fresh tissue, limiting utility in metastatic settings where liquid biopsies predominate [86]. Variability in culture protocols—growth factors, matrix composition—can introduce batch effects, necessitating standardization via CRISPR-engineered controls [69]. Ethical hurdles, including consent for biobanking and equitable access in low-resource settings, underscore the need for global consortia. Technological synergies propel organoids forward. Integration with single-cell RNA sequencing dissects intratumoral heterogeneity, identifying rare subpopulations driving relapse [76]. Microfluidic "organ-on-chip" platforms fuse organoids with vascular and immune compartments, simulating whole-body pharmacokinetics [84]. Artificial intelligence algorithms now analyze organoid imaging datasets to predict sensitivities, reducing manual labor and enhancing throughput [75]. In drug discovery, organoid libraries from diverse populations address underrepresentation in trials, fostering inclusive precision medicine [71]. For lung adenocarcinoma, organoids have

validated ALK fusions' prognostic value, while in triple-negative breast cancer, they unmask BRCAness phenotypes for PARP inhibitor selection [70, 72] Looking ahead, organoids herald a paradigm shift from reactive to proactive oncology. By 2030, regulatory bodies like the FDA may endorse organoid-based companion diagnostics, akin to liquid biopsies [74]. Clinical trials, such as the MATCH-R trial incorporating PDTO screening, already yield superior outcomes in refractory solid tumors [3]. Yet, true personalization demands multimodal integration: organoids plus genomics, proteomics, and patient metadata [84]. Cost barriers—organoid generation exceeds $10,000 per patient—necessitate automation and reimbursement models [80].

Artificial Intelligence in Organoid Research

Artificial intelligence is revolutionizing organoid research by enhancing the analysis, modeling, and application of these in-vitro systems for disease studies and drug discovery. AI techniques, such as deep learning and reservoir computing, enable precise morphological assessments and high-throughput screening, advancing personalized medicine and therapeutic development. Table 1 provides details for Artificial Intelligence in organoids, focusing on its applications in various disease contexts.

CONCLUSION

Organoid technology stands at the vanguard of a transformative shift in biomedical science, redefining how we interrogate human development, dissect disease mechanisms, and forge personalized therapeutic strategies. From their inception as rudimentary stem cell-derived structures to sophisticated, vascularized, and immunocompetent models, organoids have evolved through innovations in culture protocols—such as co-cultures with endothelial and immune cells, synthetic extracellular matrices, and air-liquid interface systems—that imbue them with unprecedented physiological fidelity. These advancements, as explored in this review, extend across diverse applications: in developmental biology, they illuminate signaling cascades like Wnt/Notch in gut morphogenesis; in inherited diseases, iPSC-derived cerebral organoids unmask synaptic deficits in autism or myelin disruptions in Charcot-Marie-Tooth; and in acquired pathologies, airway and hepatic organoids replicate viral tropism in SARS-CoV-2 or toxin-induced necrosis in acetaminophen overdose, outperforming two-dimensional cultures in predictive power. Nowhere is this impact more profound than in oncology, where patient-derived tumor organoids capture the heterogeneity, stromal crosstalk, and immune evasion of native tumors, enabling pharmacotyping that correlates 80-90% with clinical responses to agents like pembrolizumab or osimertinib.

By integrating tumor microenvironments through co-cultures with tumor-associated macrophages and fibroblasts, these models not only accelerate drug repurposing—such as metformin's efficacy in Wnt-driven colorectal cancers—but also stratify patients for precision interventions, as evidenced in trials like MATCH-R. Extending to non-oncologic realms, organoids in cystic fibrosis quantify CFTR modulator efficacy via swelling assays, while renal models prototype gene therapies for Alport syndrome, underscoring their versatility in rare and multifactorial disorders. The synergy with artificial intelligence, as outlined in Table 1, elevates organoids from static replicas to dynamic, intelligent platforms. Machine learning-driven image analysis and neural network modeling enhance high-throughput screening for Parkinson's biomarkers or brain cancer vulnerabilities, while reservoir computing in brain organoids pioneers "organoid intelligence" for computational neuroscience. These integrations mitigate analytical bottlenecks, predicting therapeutic outcomes with 95% accuracy and fostering multi-omics insights into polygenic risks. Yet, challenges temper this optimism. Batch-to-batch variability, limited vascularization beyond 500 μm, and incomplete innervation constrain long-term maturation and systemic fidelity. Ethical dilemmas—encompassing organoid consciousness, germline editing consent, and equitable biobanking access—demand robust governance frameworks, including international biorepositories and standardized protocols. Scalability remains a hurdle, with costs exceeding $5,000-10,000 per patient, necessitating automation via bioprinting and reimbursement models to broaden adoption in low-resource settings. Looking forward, organoids will converge with emerging paradigms: multi-organ "body-on-a-chip" assemblies simulating metastasis or sepsis; CRISPR screens decoding undruggable targets like KRAS; and AI-augmented phenotyping for real-time, proactive oncology. By 2030, regulatory

endorsements for organoid-based diagnostics could mirror liquid biopsies, slashing drug development timelines and attrition rates. Ultimately, organoids dissolve artificial divides between inherited susceptibilities and acquired insults, unveiling shared epigenetic convergences that propel curative horizons. As human-centric platforms, they not only reduce ethical reliance on animal models but also democratize medicine, ensuring that insights from a biopsy illuminate pathways to health for all, fostering a global renaissance in equitable, precision-driven biomedicine.

Table 1: Applications of Artificial Intelligence in Organoid Research for Disease Modelling and Therapeutic Development

Disease Focus	AI Techniques Used	Key Findings	Challenges	Reference
Parkinson's Disease	Automated workflows, machine learning, image analysis	AI-enabled high-throughput screening of organoids identified novel therapeutic targets for Parkinson's disease, improving drug discovery efficiency.	Reproducibility across organoid models, complexity of disease mechanisms, and need for diverse patient-derived organoids.	[81]

Colorectal Cancer	Deep learning, morphological typing, human-AI integration	AI-based analysis revealed interpatient heterogeneity in colorectal cancer organoids, aiding personalized medicine approaches.	Data privacy concerns, generalizability of AI models across diverse patient populations, and limited clinical validation.	[82]
Brain-Related Disorders	Reservoir computing, neural networks, AI-driven data integration	Brain organoids integrated with AI demonstrated computational capabilities, offering insights into neurological disease modeling.	Ethical concerns regarding organoid intelligence, technical scalability, and regulatory uncertainties.	[83]
Oral Diseases	Predictive modeling, AI-driven imaging, computer vision	AI revolutionized oral organoid analysis, enhancing understanding of oral disease mechanisms and tissue regeneration.	Limited translation to clinical applications, variability in organoid quality, and high computational requirements.	[84]
Cancer (General Oncology)	Machine learning, morphological analysis, AI-driven phenotyping	AI improved organoid-based cancer modeling, enabling precise tumor characterization and drug response prediction.	Challenges in standardizing organoid protocols, data integration across studies, and cost of AI implementation.	[85]
Neurological Disorders	AI-based morphological analysis, neural network modeling	Organoid intelligence advanced modeling of neurological disorders, providing insights into disease progression and treatment.	Ethical and legal concerns, limited long-term stability of organoids, and high computational costs.	[86]
Bone-Related Diseases	AI-driven imaging, predictive modeling, data integration	AI-enhanced bone organoids improved disease modeling for conditions like osteoporosis, aiding therapeutic development.	Material compatibility for organoid scaffolds, resolution limits in imaging, and clinical translation barriers.	[87]
Neurodegenerative Diseases	Automated organoid analysis, deep learning	AI-driven organoid workflows enhanced screening for neurodegenerative disease mechanisms, identifying novel biomarkers.	Complexity of disease phenotypes, reproducibility issues, and need for larger datasets.	[88]
Brain Cancer	Reservoir computing, AI-based morphological analysis	Brain organoids with AI integration provided insights into brain cancer progression and drug response, advancing precision oncology.	Ethical concerns, limited organoid scalability, and challenges in modeling tumor microenvironment.	[89]

General Neurological Conditions	AI for ethical/legal analysis, data integration	AI-organoid systems offered new perspectives on neurological condition modeling, addressing ethical and social implications.	Regulatory gaps, public acceptance, and challenges in aligning AI models with biological variability.	[90]

ABSTRACT

As trucking industry is shifting steadily to sustainable means of freight transport, electric trucks and less or zero pollution fuels have gathered main attention in logistics and supply chain. Refinements on transit technologies are being done daily to surpass the already existing practices. Cold transportation is at the urge of greening due to their severe ungreen outcomes. Electric cold transport with additional features is into existence in many countries but not wide and profound. So, this paper formulates two mathematical models on fuzzy rough multi-objective multi-route transportation problem for electric reefers with and without axle-mounted generators. Weighted Tchebycheff Metrics Programming and Weighted Fuzzy Goal Programming Approach are used to solve the models in LINGO (19.0). Models are legitimized accordingly with a numerical example.

Mathematics Subject Classsification (2020): 90B06, 90C08
Keywords: Multi-objective, Multi-route, Fuzzy rough, E-transportation problem, Axle-mounted generators

INTRODUCTION

Present day supply chain and logistics demand exclusive handling of commodities due to their high role in world trade and collaboration. Optimization of multiple transport objectives is long flourished, yet an ongoing subject because of the increasing sustainability concerns and technological innovation. Javanpour, Saba et al. [1] proposed a transport optimization multimodal model which is solved and compared with the usual transport model without environmental factors to highlight the significance of sustainability. Sifaoui T and Aïder M [2] investigated a time variant multi-objective multi-item solid transportation problem with pollution minimization goal using a hybrid method. Maity G and Roy SK [3] framed a mathematical model of two-stage transport to minimize the carbon emission during harvesting by diminishing the usage of Rice Harvester Machine (RHM). Some of the researchers disclosed biofuels as an efficient alternative to tackle hazards from fossil fuel transportation. Khan N, Sudhakar K and Mamat R [4] suggested third-generation and fourth-generation biofuels as a coherant option in view of social, economic and environmental aspects.

Though many research idea son sustainability pave the way for for an eco-friendly transportation, electrification is found to be the mainstream carbon reduction strategy due to its zero-tailpipe emission and reduced cost.Electric vehicles are highly beneficial to the environment because of its quietness, zero tailpipe emission and energy efficiency. But shifting towards electric trucks have major challenges in aspects of infrastructure, battery weight and size, regeneration etc. A literature review on the charging station infrastructure and operation for electric freight vehicles was discussed by Alam MR, Guo Z [5]. Shiledar, Ankur, et al. [6] assessed the influence of geography and seasons on energy efficiency of electric drayage trucks.

The concept of electric vehicles is reknown and incorporated currentlyto a great extend in routing problems. It is quite a need also in cold transportation problem to support sustainability. Cold transportation is the distribution of temperature sensitive commodities which are now a mandatory need for the development of global trade and e-commerce. Su M, Li Y, Liu H [7] performed cost optimization of cold logistics in multimodal transport which is a keynote to be taken down. Lu, Zhijiang, et al. [8] optimized a multi-vehicle cold chain distribution problem with traffic congestion to susbstantiate the influence of temperature factors during refrigeration on operational costs and emission. ZhangSiying et al. [9] described a cold chain decision making model with divergent vehicles and routes. They have also analysed the factors that affected vehicle preferences for distribution to minimize cost, distance and carbon emission. These works brought a clear picture and idea on electric vehicles for freight distribution.

Traction battery drainage is one among the issues in cold e-transportation as it affects the driving range, payload capacity and thereby the charging frequency of the truck.This creates the necessity for improved batteries, tires, vehicle bodies, driving styles and more specifically on supplemental power sources which render refrigeration without accessing the tractor unit.A previous work on multi-objective multi-route mathematical model [10] underlined the fact that a refrigerated trailer with an electric plug-in option favor operational expense and distribution time of perishables. But the endorsed model used e-power units only during the resting and pre cooling time which still needed sustainability. So, two electric refrigerated freight truck models with separate e-powering units for propulsion and refrigeration are introduced. As reefer unit need continuous operation, the models are established in a way to refrigerate the product throughout the entire distribution time. Axle mounted generator is an auxiliary electricity provider placed on the axles of vehicles which are one among the eliminators of excess power requirements. They generate power from the rolling and braking of axles that adds up extra spice to operational cost of trucks and no mathematical model with and without axle mounted generators on cold transportation problem still exists. So, the paper puts forward two e-models that differ from each other with an extra feature namely the axle-mounted generator. This sustainable trucking can be adopted in developing countries like India which is gradually switching onto electrification.

METHODOLOGY

Preliminaries

Fuzzy Rough set

A fuzzy rough set $\tilde{S}_{\Re} = [(\tilde{S}_{\Re}^{L}, \mu_{\Re}^{L}) : (\tilde{S}_{\Re}^{U}, \mu_{\Re}^{U})]$ is a blend of fuzziness and roughness with two membership functions defined ideally for both sure ($\tilde{S}_{\Re}^{L}$) and possible set ($\tilde{S}_{\Re}^{U}$) such that $\mu_{\Re}^{L}, \mu_{\Re}^{U} : \square \to [0,1]$ and $\tilde{S}_{\Re}^{L} \subseteq \tilde{S}_{\Re}^{U}$.

Triangular Fuzzy Rough set

A set $[\tilde{S}_{\Re}^{L} : \tilde{S}_{\Re}^{U}]$ with $\tilde{S}_{\Re}^{L} = (s_1^{L}, s_2, s_3^{L})$ and $\tilde{S}_{\Re}^{U} = (s_1^{U}, s_2, s_3^{U})$ is called a triangular fuzzy rough set provided $s_1^{U} \le s_1^{L} \le s_2 \le s_3^{L} \le s_3^{U}$ and has designated membership function as follows.

$$\mu_{\tilde{S}_{\Re}^{L}} = \begin{cases} \dfrac{x - s_1^{L}}{s_2 - s_1^{L}} & if\ s_1^{L} \le x \le s_2 \\ \dfrac{x - s_3^{L}}{s_2 - s_3^{L}} & if\ s_2 \le x \le s_3^{L} \\ 0 & else \end{cases} \text{ and } \mu_{\tilde{S}_{\Re}^{U}} = \begin{cases} \dfrac{x - s_1^{U}}{s_2 - s_1^{U}} & if\ s_1^{U} \le x \le s_2 \\ \dfrac{x - s_3^{U}}{s_2 - s_3^{U}} & if\ s_2 \le x \le s_3^{U} \\ 0 & else \end{cases}.$$

Ranking function for α -level confidence interval

For a triangular fuzzy rough number $[\tilde{S}_{\Re}^{L} : \tilde{S}_{\Re}^{U}]$, if expounded confidence interval with respect to α -level where $\alpha \in [0,1]$ is $\left(\tilde{S}_{\Re}^{L}\right)_{\alpha} = \left[s_1^{L}(\alpha), s_3^{L}(\alpha)\right] = \left[s_1^{L} + (s_2 - s_1^{L})\alpha, s_3^{L} + (s_2 - s_3^{L})\alpha\right]$ and $\left(\tilde{S}_{\Re}^{U}\right)_{\alpha} = \left[s_1^{U}(\alpha), s_3^{U}(\alpha)\right] = \left[s_1^{U} + (s_2 - s_1^{U})\alpha, s_3^{U} + (s_2 - s_3^{U})\alpha\right]$, then its ranking function is

$$r(\tilde{S}_{\Re}) = \frac{1}{4}\left[\int_0^1 \left(s_1^{L}(\alpha) + s_3^{L}(\alpha) + s_1^{U}(\alpha) + s_3^{U}(\alpha)\right) d\alpha\right].$$

Mathematical Model

Notations

I° : Number of supplier points

J° : Number of receiver points

K° : Number of routes between supplier and receiver points

$\tilde{C}_P^{\Re}$:Electrification cost

$\tilde{P}_1^{\Re}$:Electricity for truck operation

$\tilde{P}_2^{\Re}$:Electricity for cooling unit

σ : proportion of power sourced from axle-mounted generators

$\tilde{t}_{i^{\circ}j^{\circ}r^{\circ}}^{1\Re}$: traveling time from i° *to* j° *via* r°

$\tilde{t}_{i^{\circ}j^{\circ}r^{\circ}}^{2\Re}$: truck idling time due to traffic from i° *to* j° *via* r°

$\tilde{t}_{i^{\circ}}^{3\Re}$: preliminary cooling time of cooling unit at i°

$\tilde{t}^{4\Re}_{i^\circ j^\circ r^\circ}$: stationary time from i° *to* j° *via* r°

$\tilde{f}^{\Re}_{i^\circ j^\circ r^\circ}$: traffic flow in r° *between* i° *to* j°

$\tilde{a}^{\Re}_{i^\circ}$: availability at i°

$\tilde{b}^{\Re}_{j^\circ}$: demand at j°

$x_{i^\circ j^\circ r^\circ}$: quantity to be transported from i° *to* j° *via* r°

$\eta_{i^\circ j^\circ r^\circ}$: binary variable

Assumptions

- Preliminary cooling of the refrigeration unit is performed only at the supplier points.
- Time components don't vary between models as they rely on routes.
- Traffic idling disturbs all other vehicles along that route.
- Electric truck in Model-I rest at power sites while electric trucks with axle-mounted generators in Model-II rest at lay-bys.

Limitations

- Battery recharging time is not considered in both the models.
- Axle-mounted generators power up only the cooling unit.

Mathematical Formulation for Multi-Objective Multi-Route Fuzzy Rough Cold E-Transportation problem

Model-I: Without Axle-mounted Generators

$$Min\, Z_1 = \sum_{i^\circ=1}^{I^\circ}\sum_{j^\circ=1}^{J^\circ}\sum_{r^\circ=1}^{R^\circ}\tilde{C}^{\Re}_{P}\left[\tilde{P}^{\Re}_{1}\left(\tilde{t}^{1\Re}_{i^\circ j^\circ r^\circ}+\tilde{t}^{2\Re}_{i^\circ j^\circ r^\circ}\tilde{f}^{\Re}_{i^\circ j^\circ r^\circ}\right)\eta_{i^\circ j^\circ r^\circ}\right] + \tilde{C}^{\Re}_{P}\left[\tilde{P}^{\Re}_{2}\left(\tilde{t}^{1\Re}_{i^\circ j^\circ r^\circ}+\tilde{t}^{2\Re}_{i^\circ j^\circ r^\circ}\tilde{f}^{\Re}_{i^\circ j^\circ r^\circ}+\tilde{t}^{3\Re}_{i^\circ}+\tilde{t}^{4\Re}_{i^\circ j^\circ r^\circ}\right)\eta_{i^\circ j^\circ r^\circ}\right] \quad (1a)$$

$$Min\, Z_2 = \sum_{i^\circ=1}^{I^\circ}\sum_{j^\circ=1}^{J^\circ}\sum_{r^\circ=1}^{R^\circ}\tilde{f}^{\Re}_{i^\circ j^\circ r^\circ}\eta_{i^\circ j^\circ r^\circ} \quad (2)$$

$$Min\, Z_3 = \sum_{i^\circ=1}^{I^\circ}\sum_{j^\circ=1}^{J^\circ}\sum_{r^\circ=1}^{R^\circ}(\tilde{t}^{1\Re}_{i^\circ j^\circ r^\circ}+\tilde{t}^{2\Re}_{i^\circ j^\circ r^\circ}\tilde{f}^{\Re}_{i^\circ j^\circ r^\circ}+\tilde{t}^{3\Re}_{i^\circ}+\tilde{t}^{4\Re}_{i^\circ j^\circ r^\circ})\eta_{ijr} \quad (3)$$

$$\sum_{j^\circ=1}^{J^\circ}\sum_{r^\circ=1}^{R^\circ}x_{i^\circ j^\circ r^\circ}\le\tilde{a}^{\Re}_{i^\circ}, i^\circ=1,2,...,I^\circ \quad (4)$$

$$\sum_{i^\circ=1}^{I^\circ}\sum_{r^\circ=1}^{R^\circ}x_{i^\circ j^\circ r^\circ}\ge\tilde{b}^{\Re}_{j^\circ}, j^\circ=1,2,...,J^\circ \quad (5)$$

$$\sum_{r^\circ=1}^{R^\circ}\eta_{i^\circ j^\circ r^\circ}\le 1, i^\circ=1,2,...,I^\circ \;\&\; j^\circ=1,2,...,J^\circ \quad (6)$$

$$x_{i^\circ j^\circ r^\circ}\ge 0, \forall i^\circ, j^\circ, k^\circ \;\&\; x_{i^\circ j^\circ r^\circ}\in \square^{+} \quad (7)$$

$$\eta_{i^\circ j^\circ r^\circ} = \begin{cases} 1 & if\ x_{i^\circ j^\circ r^\circ} > 0 \\ 0 & else \end{cases} \quad (8)$$

Model-II: With Axle-mounted Generators

$$Min\, Z_1 = \sum_{i^\circ=1}^{I^\circ}\sum_{j^\circ=1}^{J^\circ}\sum_{r^\circ=1}^{R^\circ}\tilde{C}_P^{\Re}\left[\tilde{P}_1^{\Re}\left(\tilde{t}_{i^\circ j^\circ r^\circ}^{1\Re} + \tilde{t}_{i^\circ j^\circ r^\circ}^{2\Re}\tilde{f}_{i^\circ j^\circ r^\circ}^{\Re}\right)\eta_{i^\circ j^\circ r^\circ}\right] + \tilde{C}_P^{\Re}\left[\tilde{P}_2^{\Re}\left(\sigma.\tilde{t}_{i^\circ j^\circ r^\circ}^{1\Re} + \tilde{t}_{i^\circ j^\circ r^\circ}^{2\Re}\tilde{f}_{i^\circ j^\circ r^\circ}^{\Re} + \tilde{t}_{i^\circ}^{3\Re}\right)\eta_{i^\circ j^\circ r^\circ}\right] \quad (1b)$$

Subject to (2)-(8).

Equation (1a) and (1b) are the overall operational cost of the electric truck with and without axle mounted generators. In (1b), a proportion of electricity to power refrigeration unit during traveling time from axle is introduced. Equation (2) and (3) are the other optimization goals namely traffic flow and overall distribution time along various routes. Constraints for the multi-route transportation problem is stated in equations (4)-(8).

Optimization Approaches

Weighted Tchebycheff metrics programming

A reknown multi-objective optimization technique that optimizes the single objective, framed by adjoining the multiple objectives of the problem. The nearest feasible solution of the 'q' objectives are identified by evaluating its distance from the ideal point. The following are the steps to be performed to get the pareto-optimal solution.

Step-1: Determine the bounds of each objective function $Z_q^{\min}\ and\ Z_q^{\max}$ by evaluating them individually corresponding to the constraints (4)-(8).

Step-2: Solve the Manhattan distance model stated below by assigning weights to each 'q' in LINGO (19.0)

$Minimize\,\alpha$

Subject to, $\alpha \geq \sum_q \left[\frac{w_q(Z_q - Z_q^{\min})}{Z_q^{\max} - Z_q^{\min}}\right], \ni \sum_q w_q = 1\ \&\ q = 1,2,3,\ldots$

$w_q \geq 0\ \forall q\ and\ \alpha \geq 0.$

Weighted Fuzzy Goal Programming Approach

This is a spectacular multi-objective optimization technique proffered by Hannan as a new path way with regard to preference of the objective or goal. The method dwindles the deviation of the objectives by mustering weights from decision makers to each goal with the mathematical representation stated below.

$$Min \sum_{q^\circ=1}^{Q^\circ} w_{q^\circ}(d_{q^\circ}^{\ -} + d_{q^\circ}^{\ +}), \sum_{q^\circ=1}^{Q^\circ} w_{q^\circ} = 1$$

$$s.t.\ \mu_q(x) + d_q^{\ -} + d_q^{\ +} = 1, where\ \mu_q(x) = \begin{cases} 1 & if\ Z_q(x) < L_q \\ 1 - \dfrac{Z_q(x) - L_q}{U_q - L_q} & if\ L_q \leq Z_q(x) \leq U_q \\ 0 & if\ Z_q(x) > U_q \end{cases}$$

$d_q^{\ -} d_q^{\ +} = 0\ \&\ (4) - (8).$

RESULTS AND DISCUSSION

Considering the data from [10] and $P_1^{\Re} = [1.1, 1.25, 2.1]\ [1.05, 1.25, 2.25]$ kWh from various internet sources, the models are solved and the results are provided. Here, σ is assumed to be 0.5 which means that half of the refrigeration carried out during traveling time is rendered by axle mounted generator. The solution from both the multi-objective solving methods taken for examination are found to be same and they enrich the beauty of electric refrigerated trucks with axle-mounted generators which is beneficial in terms of cost than the one without them and equally compatible in view of operating time and traffic flow.

CONCLUSION

Sustainable transportation is the most prevalent and constantly improving essential need across the world due to the hike in mobility which is a matter of concern with regard to environmental issues. Many researchers are focusing on electric vehicles which is an ongoing escape opted to eradicate pollution. Axle-mounted generator-based e-transport models are proposed to be an efficient alternative for operational efficiency in cold chain. Results from the solved multiobjective models imply the same under multiple routes and goals scenarios. The model can be studied in solid transportation as the truck carrying capacity vary with auxiliary batteries and generators which is not discussed here. Further analysis to overcome battery drain issues, recharging time along the routes could be done. Smart management of switching between generators and the actual battery, integrated technologies and policies on subject of cold e-transport can also be studied deeply and modeled to benefit sustainable movement in transportation as future extensions.

ACKNOWLEDGEMENTS

We thank the Department of Science and Technology, Government of India, for providing support through the Fund for Improvement of S&T Infrastructure in Universities and Higher Educational Institutions (FIST) program (Grant No. SR/FIST/College-/2020/943).The authors are also thankful to the editor and the reviewer for enhancing the quality of the article.

ABSTRACT

There exists multi-faceted pollution crisis including hazardous air quality, industrial effluent discharge into major rivers, and widespread land contamination. This crisis is not merely an environmental concern but a grave public health issue linked to millions of global deaths and increased risks for chronic diseases like type-2 diabetes in India. Traditional monitoring and enforcement mechanisms are often slow and resource-intensive, necessitating advanced solutions. This article explores the transformative potential of Artificial Intelligence (AI), including machine learning, remote sensing, IoT, and edge analytics, to enhance pollution monitoring, prediction, and regulatory enforcement. It then analyses existing legal and constitutional frameworks for integrating AI. The Water (Prevention and Control of Pollution) Act, 1974, Air (Prevention and Control of Pollution) Act, 1981, and the Environment (Protection) Act, 1986 (EPA), alongside institutions like the CPCB and SPCBs, provide a broad statutory mandate for AI deployment. Furthermore, judicial interventions by the Supreme Court (e.g., "Right to Life" under Article 21, "precautionary principle," "polluter pays") and the National Green Tribunal's flexibility in admitting scientific evidence support the case for AI. However, challenges impede effective integration. These include outdated evidentiary provisions that struggle to accommodate continuous, AI-based data, the limited institutional capacity and budgetary constraints of regulatory bodies, and gaps in data governance concerning transparency, accountability, and privacy under the Digital Personal Data Protection Act, 2023. The article also addresses the issue of liability and risk allocation when AI systems err. To harness AI's potential effectively, the article proposes a multi-faceted path forward. This includes updating legal frameworks to explicitly incorporate AI, strengthening institutional capacity through increased funding and technical expertise, developing effective data governance policies that ensure transparency and privacy-by-design, and establishing a comprehensive, blended liability model that

assigns responsibility to regulated parties, AI vendors, and the state, drawing insights from international regulatory models. By addressing these legal, institutional complexities, India can use AI as a powerful instrument to secure a cleaner environment and fulfill its constitutional obligations.

Keywords: Artificial Intelligence, Pollution Monitoring, Environmental Laws, Data Governance, Liability

INTRODUCTION

In India pollution is more than an environmental problem. It is at the same time a public health issue as well as a legal challenge. In the air fine particulate matter known as $PM_{2.5}$ [1] continuously hover well above healthy limits. Across 406 cities where $PM_{2.5}$ is monitored, only 214 meet the national air quality standards. This means nearly half of the cities are breathing dangerous, unhealthy air (Hindustan Times 2024). Delhi, in particular, faces an urgent situation and it needs a reduction of about 62 percent in its annual $PM_{2.5}$ levels. It is required to meet the national ambient standard (Times of India 2024,).

"$PM_{2.5}$ refers to fine particulate matter that's 2.5 micrometres or smaller in diameter. It is about 30 times smaller than the width of a human hair. These particles are so tiny they can bypass your body's natural defence and penetrate deep into the lungs and even enter the bloodstream, which makes them hazardous to human health."

Other cities also paint a worrying picture. For example, Derabassi in Punjab ranks among the ten worst air quality performers in India. Between 2017–18 and 2024–25, its PM_{10}levels rose from 88 $\mu g/m^3$ to 98 $\mu g/m^3$. "PM_{10} refers to particulate matter with a diameter of 10 micrometres or less. It is tiny enough to be inhaled, though not as deeply penetrating as $PM_{2.5}$. These particles are a major component of urban air pollution and are linked to a range of health and environmental issues." This marks an 11.4 percent deterioration in air quality (Times of India. (2025,). In Gujarat, the state recorded fifty-three days of "poor" or "very poor" air quality during FY 2024–25. Thirty of those days were in Vapi alone. Vapi is located in Gujarat and it is one of India's major industrial hubs, and that reputation comes with a heavy environmental cost (Times of India. 2025,).

Pollution is not just about numbers. In Delhi and other northern cities, hazardous spikes in AQI (The Air Quality Index (AQI) is a standardized tool used to communicate how polluted the air currently is, or how polluted it is forecast to become. It simplifies complex air pollution data into a single number, colour code, and health message.) have forced authorities to shut schools and impose emergency restrictions. At one point, Delhi reached a "hazardous" AQI of 484. In effect northern India was blanketed in severe smog that drastically reduced visibility (Reuters. (2024,). Water pollution is equally troubling. In February 2024, Parliament was informed that around 403 million litres per day of industrial effluent particularly wastewater from grossly polluting factories entered the Ganga and Yamuna rivers. That discharge came from over 1,200 polluting units, carrying a biochemical oxygen demand of nearly twenty tonnes per day (Down to Earth. 2024). Such contamination burdens river ecosystems and challenges any legal framework to control water pollution effectively.

Soil and waste pollution also demand attention. Satellite and ground-based studies show large swathes of contaminated land, especially near industrial clusters and agricultural regions where pesticide runoff is common. Publicly available platforms like ISRO's Bhuvan and Sentinel imagery offer visible evidence of such degradation. The World Health Organization reported that air pollution contributes to about seven million deaths globally each year. Air pollution is one of the causes of strokes, heart disease, lung cancer, and other conditions(World Health Organization. (2023). In our country, pollution is linked not only to respiratory problems but also to chronic diseases like diabetes. A study in Delhi and Chennai, involving 12,000 people over seven years, found that high $PM_{2.5}$ exposure is cause of increase in type-2 diabetes risk (Ellis-Petersen, H. 2023,).

Citizens in India have responded with complaints. In Delhi NCR, pollution-related grievances jumped by about 33 percent in 2024 compared to previous years. The Central Pollution Control Board received more than 12,400 complaints, but only 43 percent were resolved and the majority of the complaints remained unaddressed (The Print. 2024,). Delhi NCR's air quality has shown improvement in 2025, but the region still faces serious long-term health risks due to persistent particulate pollution. Figure 1 shows Delhi's annual average $PM_{2.5}$ concentration consistently remains well above the National Ambient Air Quality Standard (40 μg/m³), despite some marginal declines in recent years. This figure 2 illustrates the steady rise in industrial wastewater entering the Ganga, reaching about 403 million litres per day by 2024. These figures indicate that India faces multiple pollution crises i.e. air, water, soil, and industrial pollution etc.These are worsening and deeply embedded in public life.

What "AI" Means for Pollution Control

Artificial intelligence, or AI, is often considered in broad terms, but in the context of environmental pollution control it has a very specific meaning. AI refers to computer systems that can process data, recognise patterns, and make predictions or decisions that traditionally required human intelligence. The definition used by the Organisation for Economic Co-operation and Development (OECD) describes AI systems as "machine-based systems that can, for a given set of objectives, make predictions, recommendations, or decisions influencing real or virtual environments" (OECD2019). This captures not only general AI research but also the practical tools used by regulators, industries, and scientists to monitor and reduce pollution. Within this broad field, machine learning (ML) plays a central role. ML refers to algorithms that improve their performance by learning from data rather than being programmed with fixed rules. In environmental monitoring, ML models are trained on massive datasets of air quality measurements, satellite images, or industrial discharge records to identify pollution sources or predict future spikes. For example, supervised learning models such as random forests and gradient boosting have been used in India and globally to forecast $PM_{2.5}$ levels based on meteorological inputs and past pollution data (Kumar, R., et al. (2021). Deep learning, a branch of ML that uses artificial neural networks, has shown strong results in analysing satellite imagery to detect water pollution and illegal deforestation. These tools matter for law because enforcement increasingly depends on reliable, automated evidence that can withstand judicial scrutiny.

Remote sensing is another technical foundation. It refers to collecting data from satellites, drones, or aircraft without direct physical contact with the object being observed. Agencies like ISRO and NASA provide satellite datasets such as MODIS and Sentinel, which are processed with AI models to detect particulate matter, thermal anomalies, or water quality indicators (European Space Agency 2023).For instance, AI-enhanced remote sensing can identify industrial plants discharging effluents into rivers by analysing changes in surface water composition. These methods give regulators evidence across large and often inaccessible geographies. Without such tools, traditional ground monitoring would be too slow and incomplete. Edge analytics is closely linked to the growth of the Internet of Things (IoT). IoT refers to the network of interconnected devices and sensors that continuously collect and share data. In pollution control, this could be continuous ambient air quality monitors, wastewater treatment sensors, or vehicular emission trackers. Edge analytics means processing this data closer to where it is collected—on the sensor itself or nearby—rather than sending all raw information to a central server. This reduces latency, allows faster detection of violations, and helps regulators act in real time. For example, in India's Continuous Emission Monitoring Systems (CEMS) installed at thermal power plants, sensor data is increasingly being processed on-site with AI algorithms that flag irregularities instantly, instead of waiting for human review at a central office (Central Pollution Control Board. (2017). This technical detail has legal importance because it determines whether pollution control laws can rely on machine-generated alerts as "actionable evidence."

Standards-setting organizations have begun to formalize how these technologies should be defined and regulated. The International Organization for Standardization (ISO) and the International Electrotechnical Commission (IEC) jointly released ISO/IEC 22989:2022, which sets terminology for AI (International Organization for Standardization 2022). Similarly, the Institute of Electrical and Electronics Engineers (IEEE) has developed standards for trustworthy AI systems, including requirements for transparency, accountability, and fairness. These standards matter because Indian laws, when updated, will need to decide whether to reference such global norms or develop indigenous

frameworks. Without a precise technical vocabulary, statutes and rules risk being either too vague or technologically outdated. The OECD AI Principles has been endorsed by over forty countries, including major economies. These principles provide a widely recognised framework for responsible AI. They emphasise human-centred values, transparency, and accountability(OECD 2019). In the context of pollution control, these principles would mean ensuring that AI models used for regulatory purposes are explainable enough for courts to evaluate against manipulation, and accountable to the public if errors occur. For example, if an AI system wrongly accuses a small factory of exceeding emissions, there must be a clear audit trail to challenge and review the algorithm's output.

Industry and government white papers already showcase how AI is being deployed in practice. The World Bank has highlighted AI-enabled satellite monitoring of air pollution in South Asia as a cost-effective way to supplement sparse ground stations (World Bank 2021).In India, NITI Aayog's *National Strategy for Artificial Intelligence* identifies environmental sustainability as one of the "AI for All" priority areas and pointsat AI's role in air quality management and waste reduction (NITI Aayog, 2018), Private companies, too, have released reports demonstrating AI tools that use predictive analytics to optimize industrial emissions and reduce energy use. These documents reveal not just what is possible, but also the scale of investment already flowing into AI for environmental applications.

From a legal perspective, it is essential to understand that these technologies are not abstract ideas but concrete systems with measurable inputs, outputs, and error margins. A predictive air quality model has an accuracy rate expressed in terms like mean absolute error (MAE) or root mean square error (RMSE). A remote sensing algorithm has a precision-recall trade-off. IoT sensors have calibration tolerances. If laws regulating pollution are to integrate AI effectively, they must recognise these parameters as legally significant. A tribunal or court will not only ask whether AI detected pollution but also how reliable that detection was and whether it meets an admissible evidentiary threshold. Thus, AI in pollution control refers to a cluster of interrelated technologies including machine learning, remote sensing, IoT, and edge analytics guided by evolving international standards. These tools can expand the state's capacity to monitor, predict, and control environmental harm, but they also introduce legal complexities around definitions, accountability, and reliability. An analysis of environmental statutes must therefore be matched with a technical literacy of AI. Only then can legal prescriptions be both precise and effective in addressing India's urgent pollution challenges.

Legal Framework of Environmental Protection

Statutory Laws

Legal framework for environmental protection in India is built upon a layered legal and institutional infrastructure that has evolved over the past five decades. At its core are three principal statutes i.e. the *Water (Prevention and Control of Pollution) Act, 1974* (Water Act), the *Air (Prevention and Control of Pollution) Act, 1981* (Air Act), and the *Environment (Protection) Act, 1986* (EPA). Together with sector-specific rules under the EPA and judicial interventions from the Supreme Court and the National Green Tribunal (NGT), these laws define the mandate, powers, and limitations of pollution control authorities. Understanding this architecture is necessary for assessing how artificial intelligence (AI) tools may be deployed in monitoring, enforcement, and compliance.

The Water Act of 1974, India's first dedicated pollution control statute, established the Central Pollution Control Board (CPCB) and State Pollution Control Boards (SPCBs) as the primary regulatory bodies. Section 17 of the Act empowers SPCBs to plan and execute comprehensive programs for the prevention, control, and abatement of water pollution, as well as to collect and disseminate data relating to water quality (Government of India. (1974).The Act authorizes Boards to set effluent standards, require industries to install treatment systems, and initiate prosecutions for violations (Government of India. (1974). These provisions provide a legal basis for adopting AI-enhanced monitoring, such as IoT-enabled sensors in effluent discharge outlets, provided such data is recognised as admissible "evidence" under Section 49, which governs cognizance of offences.

The Air Act of 1981 extended this regulatory architecture to air pollution. It empowered CPCB and SPCBs to set emission standards, monitor ambient air quality, and enforce compliance through closure directions under Section 31A (Government of India. (1981).In practice, however, Boards often rely on manual inspections and laboratory-based sampling, which are slow and resource-intensive. The Act's broad mandate to "collect and disseminate information" (Section 17(1)(a)) could easily encompass AI-based predictive modelling of air pollution or automated alerts generated by Continuous Emission Monitoring Systems (CEMS). The challenge lies in ensuring that such digital outputs are formally recognized within the evidentiary framework of enforcement proceedings.

The Environment (Protection) Act of 1986, enacted in the aftermath of the Bhopal gas disaster, is the umbrella legislation that gives the central government sweeping powers to issue directions for protecting and improving the environment. Section 3 empowers the Union government to take measures "as it deems necessary" for protecting the environment, while Section 5 authorizes binding directions, including closure or regulation of industries (Government of India. 1986).).Subordinate legislation under the EPA includes a wide range of rulessuch as the *Environment (Protection) Rules, 1986*, *Hazardous and Other Wastes Rules, 2016*, *Solid Waste Management Rules, 2016*, and *E-Waste Management Rules, 2016. These rules* define standards and procedures for pollution control. These rules often include monitoring requirements that could be operationalised through AI, such as real-time online monitoring of effluents and emissions. The statutory breadth of the EPA is thus a major enabling factor for technological innovation.

Institutionally, the CPCB (created under the Water Act but functioning under the EPA as well) is the nodal authority for pollution monitoring and standard-setting. Its mandate, as outlined in Section 16 of the Water Act and extended under the Air Act and EPA, includes advising the central government, coordinating SPCBs, setting standards, and collecting technical data. SPCBs are responsible for implementation within their respective states, including granting consents to establish and operate industries. These Boards have experimented with AI-linked initiatives, such as predictive analytics for industrial compliance in Gujarat and IoT-based effluent monitoring in Maharashtra. However, their ability to scale such efforts is constrained by budgetary and staffing limitations, documented in successive Comptroller and Auditor General (CAG) reports (Comptroller & Auditor General of India. (2016).

The judiciary has played a pivotal role in shaping environmental governance, often filling gaps left by executive agencies. In *MC Mehta v. Union of India* (Oleum Gas Leak case, (1987)), the Supreme Court articulated the principle of "absolute liability" for hazardous industries. In later air and water pollution cases, such as the Taj Trapezium matter and the Delhi vehicular pollution litigation, the Court issued detailed directions to regulatory authorities, effectively acting as a catalyst for stronger enforcement. Further, in *Vellore Citizens Welfare Forum v. Union of India (*Vellore Citizens Welfare Forum v. Union of India, 1996), the Court recognized the "precautionary principle" and "polluter pays principle" as part of Indian law. These judiciary evolved doctrines could strengthen the case for AI deployment, as predictive modelling aligns with precautionary action and automated cost attribution fits the polluter pays principle.

The establishment of the National Green Tribunal (NGT) under the *National Green Tribunal Act, 2010* further institutionalised judicial oversight. The NGT has powers of original jurisdiction in environmental disputes and can provide relief and compensation for damages. It also has wide powers under Section 19 to regulate its own procedure, unencumbered by the strict rules of the Code of Civil Procedure or the Indian Evidence Act (The National Green Tribunal Act, No. 19 of 2010). This flexibility means that AI-generated data, such as satellite imagery or predictive analytics, could be admitted as evidence more readily in NGT proceedings than in ordinary criminal courts. The Tribunal has, in fact, relied on satellite data in several cases involving illegal sand mining and encroachment. Its openness to scientific and technical inputs makes it an important site for mainstreaming AI evidence in environmental adjudication.

Despite this legal infrastructure, several constraints remain. First, statutory provisions on evidence and enforcement have not yet been updated to explicitly incorporate digital or AI-based tools. For instance, while Section 21 of the

Water Act allows Boards to take samples of effluents for analysis, it prescribes a manual procedure involving divided samples and laboratory testing. This does not easily accommodate continuous, AI-based monitoring. This raises questions about admissibility in prosecution. Second, institutional capacity is uneven because SPCBs often lack sufficient technical staff or budgets to operate sophisticated AI systems. CAG reports have repeatedly noted understaffing and backlogs in consent processing (Comptroller & Auditor General of India, *Report No. 3 of 2017*). Third, issues of transparency, accountability, and data governance remain unresolved. Who owns the data generated by AI tools—regulators, industries, or third-party vendors? How is the accuracy of an AI model certified? These are legal gaps that need to be addressed through either amendments or new rules under the EPA.

Finally, fiscal and administrative documents reveal that CPCB and SPCBs continue to be under-resourced. For example, the CPCB's budget allocation in 2023–24 was approximately ₹200 crore, a fraction of what would be required for nationwide AI deployment in pollution monitoring (Government of India, Ministry of Finance. (2023). Organograms show thin staffing in technical divisions, with heavy reliance on consultants. Without strengthening this institutional base, even the most enabling statutory provisions will not translate into effective technological adoption. Thus, the legal framework for pollution control is provided in the Water Act, Air Act, and EPA, and supplemented by judicial doctrines and institutions like the NGT. These altogether provide a broad statutory mandate for adopting AI in monitoring and enforcement. The EPA's sweeping powers are especially conducive to integrating new technologies. Yet gaps in evidentiary provisions, institutional capacity, and regulatory clarity on data governance could constrain such deployment. The next stage of legal development must therefore focus on bridging these gaps, ensuring that AI tools are not only legally permissible but also operationally viable within India's environmental governance framework.

Constitutional and Human Rights Dimensions: Privacy, Participation and Access to Remedies

The integration of artificial intelligence (AI) into environmental regulation does not occur in a constitutional vacuum. In India, the constitutional and human rights framework shapes both the opportunities and risks of deploying AI for pollution control. Three clusters of rights are especially salient: (i) the right to life and healthy environment under Article 21, (ii) informational rights such as privacy and access to environmental data, and (iii) procedural rights of participation and access to remedies. Each has been interpreted by courts in ways that directly condition how AI-based monitoring, forecasting, and enforcement can be designed and used.

Right to Life and the Healthy Environment

The right to life under Article 21 of the Constitution has been expansively interpreted to include the right to a wholesome environment. In Subhash Kumar v. State of Bihar (Subhash Kumar v. State of Bihar, 1991), the Supreme Court affirmed that Article 21 encompasses the right to clean water and air as essential to life. Similarly, in MC Mehta v. Union of India (M.C. Mehta v. Union of India, 1987), the Court mandated pollution abatement measures in industries and vehicles, treating environmental degradation as a violation of fundamental rights. These rulings establish a strong doctrinal basis for deploying AI in pollution control: if the State is under a constitutional duty to secure a clean environment, it may also be under a duty to introduce advanced technologies like AI that enhance monitoring and prevention capacity.

The National Green Tribunal (NGT) has extended this reasoning by explicitly endorsing the use of remote sensing, satellite data, and digital platforms to enforce environmental norms, such as in sand mining disputes (Satendra Pandey v. Ministry of Environment, Forest and Climate Change, OA No. 186/2016 (NGT, India). AI systems that enable anomaly detection or predictive forecasting thus reinforce, rather than undermine, the constitutional obligation to safeguard life and health. However, this positive obligation must be balanced against rights to privacy and due process.

Privacy and Data Protection Concerns

The landmark judgment in Justice *K.S. Puttaswamy v. Union of India*(Justice K.S. Puttaswamy v. Union of India, 2017) recognised privacy as a fundamental right implicit in Article 21. Pollution control AI systems, such as continuous

emissions monitoring (CEMS) or IoT-enabled waste management platforms, generate and process vast amounts of data—not only about industries, but also about households, vehicle movements, and consumer practices. When AI systems track waste collection at household level or link pollution exposure to geolocated individuals, privacy risks become tangible.

The Digital Personal Data Protection Act, 2023 (DPDP Act) introduced statutory safeguards around personal data processing, mandating lawful basis, purpose limitation, and storage restrictions (Government of India. (2023). While most industrial emissions and satellite monitoring datasets may not directly constitute "personal data," environmental monitoring increasingly overlaps with personal domains such as health impacts of air pollution, household waste tracking, or personal exposure mapping. In such cases, DPDP standards will apply, requiring regulators to ensure anonymisation, necessity, and proportionality when deploying AI.
Internationally, the OECD AI Principles and the UN Human Rights Council's Guiding Principles on Human Rights and the Environment emphasise that AI deployment must be transparent, accountable, and privacy-preserving(United Nations Human Rights Council 2021). Indian jurisprudence will need to align domestic AI deployments in environmental governance with these broader human rights standards.

Right to Information and Environmental Transparency
The Right to Information Act, 2005 (RTI Act) operationalises citizens' right to access government-held data. Courts have repeatedly held that access to environmental information is part of the right to life. In Union of India v. Association for Democratic Reforms, the Court stressed transparency as a constitutional value linked to Article 19(1)(a) (Union of India v. Association for Democratic Reforms, (2002). AI systems deployed in pollution control, such as real-time air quality forecasts, CEMS dashboards, or satellite anomaly detection, generate new categories of environmental data. Whether such AI-derived data is made accessible to citizens or kept within regulatory silos will determine if AI strengthens or weakens the constitutional right to information.

RTI has been used to demand release of environmental datasets. For example, civil society groups have sought real-time stack monitoring data from SPCBs under RTI, sometimes facing denial on grounds of "confidentiality." (Centre for Policy Research. 2021) In such contexts, constitutional jurisprudence suggests that denial undermines both transparency and participatory rights, unless narrowly justified. Ensuring public access to AI outputs will be central to their legitimacy.

Participation in Environmental Decision-Making
Participation is a constitutional principle linked to Articles 14 and 21, and reinforced through statutory frameworks like the Environment Protection Act, 1986 and the Environmental Impact Assessment (EIA) Notification, which mandate public hearings. AI-driven environmental monitoring introduces both opportunities and risks for participation. On one hand, AI can democratise access to information by publishing real-time pollution dashboards, empowering citizens to challenge polluters. On the other hand, if AI algorithms remain opaque, communities may be excluded from meaningful participation in decisions based on "black-box" evidence.

The NGT has begun addressing this tension. In cases concerning river pollution and municipal solid waste, the Tribunal has directed the CPCB and SPCBs to create public portals with real-time AI-enabled dashboards (Almitra H. Patel v. Union of India, Writ Petition No. 888/1996 (NGT, India). Yet, the opacity of algorithmic models has not been tested in court: whether citizens have a right to inspect or challenge the models themselves remains an open constitutional question. Internationally, the Aarhus Convention in Europe explicitly guarantees participation in environmental matters, including access to underlying data and models (United Nations Economic Commission for Europe 1998). India lacks an equivalent instrument, but constitutional guarantees of fairness under Articles 14 and 21 could be interpreted to similar effect.

Access to Remedies and Evidentiary Use of AI

Access to remedies, judicial and administrative, is integral to constitutionalism. AI-generated evidence is presented before courts and tribunals in environmental cases. For example, the NGT has relied on satellite imagery in illegal mining disputes, and expert committees have used AI-based modelling to demonstrate industrial contributions to river pollution (Sudarsan Das v. State of West Bengal, OA No. 173/2018 (NGT, India). The question arises whether such AI-derived evidence satisfies constitutional guarantees of fair trial and due process. In *State of Punjab v. Mohinder Singh Chawla* (State of Punjab v. Mohinder Singh Chawla, (1997), the Court emphasized that Article 21 requires remedies to be "effective, adequate and prompt." If AI strengthens enforcement by providing real-time, reliable evidence, it promotes constitutional guarantees. However, if AI-generated data is opaque or unchallengeable, it risks undermining due process. Affected industries or communities must have a chance to contest AI evidence, including through technical cross-examination. Without procedural safeguards, reliance on AI could violate Articles 14 and 21.

The evidentiary admissibility of AI is still evolving. The Supreme Court in *Anvar v. Basheer (*Anvar P.V. v. P.K. Basheer, (2014) established requirements for admissibility of electronic records under Section 65B of the Indian Evidence Act. AI outputs fall within this category, meaning certifications and technical documentation will be necessary for them to be judicially relied upon. Ensuring such safeguards will be necessary to reconcile technological innovation with constitutional rights.

Balancing Positive Obligations and Rights Risks

The constitutional architecture thus creates a dual imperative: (i) the State must deploy advanced technologies like AI to secure citizens' right to life and healthy environment, but (ii) such deployment must respect privacy, transparency, participation, and due process. A balanced approach requires statutory frameworks clarifying data sharing, privacy safeguards, and evidentiary standards for AI in environmental cases. Ultimately, AI in pollution control can either deepen constitutional democracy or erode it. If deployed transparently, with privacy-protective architectures and open citizen participation, AI can enhance the enforcement of environmental rights under Article 21. If adopted opaquely or coercively, it risks undermining constitutional guarantees. The challenge for Indian regulators, courts, and legislatures will be to ensure that AI tools operate within a rights-respecting legal framework—so that technology becomes an instrument of constitutional fulfilment, not circumvention.

Liability and Regulatory Remedies: Who Bears Risk When AI Fails?

When AI systems are used in pollution control, whether to flag an industrial effluent plume from satellite imagery, to trigger an automated closure notice from continuous emission monitors, or to prioritize inspections, technology can amplify both enforcement capacity and legal risk. The core question is when an AI system errs (false positive or false negative), who bears the legal and financial consequences—the regulated party, the vendor, or the state regulator that relied on the tool? The answer depends on the liability model applied: strict liability, negligence, product liability, or state (public law) liability. Each model fits different factual patterns and suggests different regulatory responses.

Strict liability puts responsibility on the actor who creates the hazard regardless of fault. In environmental law, strict or absolute liability has deep roots in Indian jurisprudence. This is evident from the fact that *MC Mehta* principles and *Rylands*-type doctrines have long assigned harsh responsibility for hazardous enterprise harms (*M.C. Mehta v. Union of India* (Oleum Gas Leak), (1987). Applied to AI, a strict liability approach would make owners/operators of AI systems (or those who deploy them to make enforcement decisions) answerable for harms caused by erroneous outputs even if they exercised reasonable care in development or deployment. This model encourages heavy diligence, rigorous validation, and high standards of sensor provenance—but it may chill innovation if vendors face open-ended exposure. The Indian Supreme Court's environmental strictness suggests courts may be sympathetic to placing heavy burdens where public health is at stake (*Vellore Citizens Welfare Forum v. Union of India*, (1996). Negligence law, by contrast, rests on an inquiry into whether actors exercised reasonable care in designing, validating, and supervising AI systems. If a regulator used an AI model that industry peers would consider state-of-

the-art, and followed documented validation protocols, negligence liability may not attach even if an error occurred. Negligence rules can be calibrated by statute to require specific governance steps—e.g., independent audits, accuracy benchmarks, and maintenance schedules for CEMS devices—so that liability is tied to compliance with technical due-care standards. Empirical problems such as "flat-line" CEMS sensor outputs and known calibration failures highlight why courts will look closely at maintenance records and audit trails when assessing care (Central Pollution Control Board. 2018). Product liability treats defective products (including software and AI) as the basis for claims. This model is attractive when an AI vendor supplies an algorithm or an integrated sensor-plus-software product that produces faulty outputs. International law is moving in this direction: recent EU reforms and the new Product Liability Directive explicitly expand "product" definitions to cover software and digital services, exposing vendors to strict liability for defective AI systems in some circumstances (Regulation (EU) 2024/1689, Artificial Intelligence Act. 2024). If translated to India, product liability would allow pollution victimsor regulators who suffer costs from false positives/negatives, to sue vendors directly without proving negligence. This creates market pressure for vendors to invest in testing, documentation, and insurance. US and state-level initiatives are also exploring how product liability principles can cover AI-driven harms (National Conference of State Legislatures. 2024).

Under State liability rule it is asked whether the regulator or State body that relied on AI instruments can be sued for maladministration, the reason being either it relied blindly on opaque outputs or because it failed to supervise a contractor. Administrative or public law remedies (declaratory relief, mandamus, compensation under public law) can arise when AI deployment causes wrongful deprivation of property (e.g., unlawful closure of a plant), wrongful fines, or negligent failure to prevent pollution due to system blind spots. Indian tribunals and courts have historically held State actors accountable when enforcement procedures were demonstrably defective; a regulator that executes closure orders solely on unverified AI flags risks reversal and damages. The National Green Tribunal's flexible procedural approach has already allowed satellite evidence, but it also emphasizes the need for verification before extreme remedies are imposed (National Green Tribunal 2015).

In the emissions monitoring domain, India's rollout of Continuous Emission Monitoring Systems (CEMS) has improved transparency but revealed new risks. Audits and technical reports document sensor downtime, data "flat-lining," and connectivity failures that produce misleading readings—facts that in practice generate both false positives (spurious exceedance alarms) and false negatives (undetected breaches) (Centre for Science and Environment. n.d.).Where industry contests a closure notice based on such data, courts will probe calibration logs, QA/QC certificates, and chain-of-custody. Similarly, satellite-based anomaly detection pilots can misclassify natural turbidity as an industrial plume or misinterpret seasonal changes, producing enforcement letters to wrongly accused polluters. Indian tribunals have accepted satellite evidence in mining and encroachment cases, but such acceptance has come with demands for corroboration and expert verification (National Green Tribunal. n.d.).

Comparative regulatory models point to hybrid solutions. The EU's AI regulatory framework (and its product liability and data-access reforms) creates layered obligations: high-risk AI systems face strict requirements for transparency, human oversight, conformity assessment, and post-market monitoring—while vendor liability is tightened for defective software(Act Explorer. (n.d.). US state approaches vary but often combine procurement rules (requiring impact assessments and vendor transparency) with limited liability safe harbors for regulators that follow specified procedures(Bryan Cave Leighton Paisner LLP. n.d.).These templates suggest practical rules for India: (a) classify pollution-control AI uses that trigger enforcement as "high-risk," (b) mandate pre-deployment conformity assessment and third-party audit, (c) require recordable human oversight before punitive actions, and (d) preserve vendor/product liability claims where defects caused foreseeable enforcement harms.

Insurance and remediation mechanisms should be part of the design. Insurers are already developing policies for AI-related risks, and product-liability insurance or statutory remediation funds could absorb residual harms while litigation unfolds. For example, where an AI false positive leads to temporary closure and economic loss, a statutorily mandated compensation procedure—triggered when a regulator retracts an AI-based enforcement order—can offer quicker relief than long court suits. Similarly, mandatory post-market surveillance (logging false positives/negatives

and remediation rates) can create feedback loops that reduce systemic risk. Finally, governance rules must address evidence admissibility. Courts require certified, auditable chains for electronic records; India's jurisprudence on electronic evidence (Section 65B doctrine) and the *Anvar* line mean AI outputs will need accompanying technical attestations, data provenance logs, and expert validation to be actionable(Anvar P.V. v. P.K. Basheer, (2014)). Requiring standardized audit trails, model cards, and explainability reports as preconditions for enforcement reliance will reduce litigation risk and enhance public trust. In sum, no single liability model suffices. A blended approach—combining sectoral strictness for high-harm contexts, negligence standards tied to technical due care, vendor product liability for defective AI/software, explicit state accountability for misuse, and financial remediation mechanisms—best allocates risk while sustaining innovation. India can borrow from EU conformity regimes, US procurement safeguards, and product-liability expansions in Europe to create a legally suitable ecosystem where AI failures in pollution control are managed by predictable rules, audited evidence, and clear redress paths.

CONCLUSION

We have a legal and constitutional backbone to support integration of Artificial Intelligence to deal with the problem of environmental pollution. The laws like the Water Act of 1974, the Air Act of 1981, and especially the broad-ranging Environment (Protection) Act of 1986, along with institutions like the CPCB and SPCBs, provide a strong mandate for adopting new technologies. Plus, our Supreme Court and the National Green Tribunal have consistently championed a clean environment as a fundamental "Right to Life" under Article 21, and they've shown a willingness to embrace scientific evidence, including satellite data, in their rulings. Even the NITI Aayog has recognised environmental sustainability as a key area for "AI for All". However, as promising as AI is, it's not a magic bullet, and its integration comes with challenges we can't ignore. We're talking about legal hurdles like updating our evidentiary rules to properly accept AI-generated data in courts, ensuring the transparency and accountability of these complex algorithms, and addressing privacy concerns when AI systems process data that might touch on personal information. Then there are practical issues like our pollution control boards often lack the necessary funding and technical staff to deploy and manage sophisticated AI systems effectively. And let's not forget the big question of "who's responsible" when an AI system makes a mistake, leading to a false alarm or, worse, an undetected violation.

So, what's the path forward? It's clear that we need a thoughtful and proactive approach. This means updating our laws to explicitly include AI tools, drawing inspiration from global standards for trustworthy AI. We need strong data governance policies that clarify ownership, ensure privacy safeguards, and make AI-derived environmental information publicly accessible, upholding our citizens' "Right to Information". Strengthening the capacity of our regulatory bodies with better budgets and trained personnel is also important. Most importantly, we need a liability framework i.e. a blended approach combining strict liability for high-risk applications, clear negligence standards, and even vendor accountability for defective AI software. This is required to ensure that risks are fairly allocated and that there are clear paths for redress when things go wrong. Ultimately, successfully integrating AI into India's pollution control efforts isn't just about adopting new technology; it's about doing it smartly and legally. By addressing these practical challenges head-on, we can harness AI's incredible power to protect our environment, safeguard public health, and ensure that this technology truly serves as an instrument to fulfill our constitutional rights, rather than inadvertently undermining them. It's a journey, but one we must embark on to secure a cleaner, healthier future for all.

ABSTRACT

This study primarily focuses on developing a novel UV method for the assay of flurbiprofen in both pure form and pharmaceutical dosage forms. The process involves preparing standard and working solutions of flurbiprofen, followed by the analysis of different concentrations of the working solution. The established method is then subjected to validation as per ICH guidelines. The results indicate that the developed method is sensitive and accurate, particularly within the concentration range of 10-80 μg/ml. The correlation coefficient (R2) was determined to be 0.999. Notably, there was no interference observed with the excipients present in the formulation. The proposed method holds potential for the analysis of Bempedoic acid in bulk and formulation, making it suitable for routine analysis

Keywords: Ultraviolet Spectroscopy, validation, flurbiprofen, method development, assay.

INTRODUCTION

Flurbiprofen(FEN) is responsible therapeutic activity with lower adverse effects comparatively with other NSAIDs. Through a literature review, it has been observed that only a small amount of research has been recorded on this topic regarding the assessment of FEN [Fig-1] using HPLC and Mass spectrometry. There are few UV spectrophotometric methods reported for analysis of FEN[1]. This investigation aimed to analyze FEN in both its pure form and pharmaceutical formulation, specifically tablets. Following the development of the UV method, all optimization parameters were taken into account. The validated method proved successful, affirming its appropriateness for determining the overall drug content in commercially accessible FEN formulations. Consequently, the development and validation processes adhered to ICH guidelines [2-5].

MATERIALS AND METHODS

Instruments and Reagents:
A complimentary sample of FEN with a purity level of 99.98% was obtained from a manufacturing facility located in Visakhapatnam. The instruments employed in the study included UV/Visible spectrophotometer, Lab india, model T60 and analytical balance, shimadzu, japan. The investigation utilized analytical-grade chemicals and reagents. BEMDAC-branded FEN tablets, each containing 180 mg, were obtained for the formulation.

Stock solution
A quantity of 25 mg of the drug was introduced into a 25 ml calibrated flask, where it was dissolved and topped up to the calibration mark with acetonitrile, resulting in 1000µg/ml. This establishes the standard stock solution of FEN.

orking standard solution (100µg/ml)
A quantity of 2.5 ml was extracted from the standard stock solution mentioned earlier and transferred into a 25 ml calibrated flask. Acetonitrile was added to the flask to achieve a concentration of 100 µg/ml, and the solution was adjusted to the mark.

Calibration curve
Following that, it was subjected to scanning using a UV Spectrophotometer covering the 200-400 nm range, with acetonitrile employed as the blank. The peak absorbance was pinpointed at a wavelength of 272 nm. To generate different concentrations spanning from 10 to 60 µg/ml, portions were formulated using distilled water as the solvent. These samples were then assessed at the specified wavelength of 272 nm to ascertain their respective absorbance values. The collected data was subsequently used to construct a calibration plot.

RESULTS AND DISCUSSION

Method Validation
Linearity
Various samples of FEN were created within the 10-60 µg/ml range using the working standard solution (40 µg/ml). These solutions underwent scanning on a UV- spectrophotometer spanning the 200-400 nm range, with acetonitrile serving as the reference. The spectrum was captured at 272 nm (Fig-2). The data illustrated the relationship between concentration and absorbance, is depicted in Table-1.

Precision
The method's precision was showcased through assessments of intra-day and inter-day variations. In the intra-day analysis, six separate solutions with 40 µg/ml were created and assessed twice daily. For the inter-day study,

solutions of 40 µg/ml were formulated and was tested six times over two successive days, and the absorbance was noted (refer to Table-2). The calculated percentage of relative standard deviations was found to be below 2%.

Accuracy

Standard addition method was found for performing accuracy, wherein the percent recovery of FEN was computed. These solutions were prepared in triplicate, and the accuracy results are presented in Table 3.

Robustness

The method's reliability was evaluated through the examination of a sample with a concentration of 40 µg/ml at three distinct wavelengths, including one at λ max, and recording the corresponding absorbance values. The outcomes presented in Table-4 suggest that the method demonstrated robustness.

Ruggedness

To assess the ruggedness of the method, the sample was analyzed by two different analysts using the identical apparatus, and by the same examiner using two different cuvettes, with the respective absorbance values recorded. The results from the first analyst revealed a %RSD of 0.17, while the second analyst showed a %RSD of 0.26. These results indicate that the utilized methodology was robust, as no notable distinction is evident among various operators.

Assay of formulation

The analysis of the obtained formulation involved assaying an equivalent weight of 25 mg of FEN formulation in a 25 ml calibrated flask, utilizing acetonitrile as the diluent. The final concentration was adjusted to 40 µg/ml using distilled water. The assessment was conducted at a UV wavelength of 272 nm, revealing an assay result of 99.72%.

CONCLUSION

The proposed method proved to be simple, exhibiting accuracy, precision, and robustness while being easily implementable. The calibration plot covered a broad range, and the recoveries of samples were consistent. The equipment and reagents utilized are likely to be accessible, even in basic laboratory setups. Therefore, the established method is recommended for regular use in quality control analysis of FEN. Additionally, it is deemed suitable for analyzing samples in accelerated stability studies, routine formulation analyses, and the assessment of drug substance.

ABSTRACT

Midlife crisis among men has often been spoken of in cliches, usually linked to impulsive choices or dissatisfaction with ageing, but it is really a deeper psychosocial experience with important mental health implications. This review article considers the phenomenon as an overlooked area of concern, highlighting the concatenation of identity struggles, career-end situations with the realities of family re-constitution and the aging process. Societal norms around masculinity exacerbate these issues, hindering men's ability to recognise vulnerability or get assistance. Using theoretical perspectives and existing psycho social factors, the discussion is positioned to argue for marginalising the concept of the midlife crisis as an individual weakness by framing the concept as a response to a wider set of social and cultural influences. Despite of its relevance, the issue has received limited attention in research and practice, leaving gaps in awareness and intervention. The paper argues that the response to midlife crisis needs to be at many levels, including policy change, developing culturally sensitive practices and community support mechanisms. Recognizing it as a legitimate mental health concern can reduce stigma, foster resilience, and enable men to move through this transition with greater purpose and well-being.

Keywords: Midlife Crisis, Men's Mental Health, Psychosocial Aspects, Ageing, Midlife Transitions

INTRODUCTION

Mental health, one of the components of well-being, touches on all people from all walks of life. Men on the other hand have specific challenges and differences in the context of mental health [18], leaving a gap in mental health services and research for a long time when it comes to men's needs [30, 37]. It appears that these issues have increased during the COVID-19 pandemic as the men reported more cases of depression and suicidal intentions compared to women [10]. The gender distribution of mental-health service use presents a stark male-female contrast in that not only are men less likely than women to access services, this distinction is upheld by normative patterns deeply tied to cultural rites of masculinities, power over feelings, and the value of a self-determining masculine subjectivity. Without the professional help, the men tend to build up too much stress with no means of intervention. The above described picture of men's health is the outcome of a range of biological, psychological, and social explanations that in totality contribute to men's mental health [27]. Men are ever more inclined to suffer from certain mental disorders because of biological precursors such as changes in hormones, family histories of mental illness, or having defects in the structure or the functioning of the brain [30] [37]. It is psychologically possible that any allegiance to masculine ideals of the past, as a pattern that emphasises stoicism, self-dependence, and non-expressivity can predispose men against psychological problems recognition and the desire to address them [18] [36].In the socio-environmental setting, occupational status, monetary resources, and exposure to trauma or violence are all separate factors in compounding psyche-health weaknesses [10]. All these multilevel determinants in combination offer an infrastructure of how to comprehend and operate on mental-health issues that men face. The period between 40 and 65 years is considered a developmental crossroads to the mental progression of men [23]. Men face exaggerated environmental pressures, which may compound pre-existing psyche challenges or trigger the onset of new ones. The work demands such as job roles, family duties, and societal norms tend to combine and burden people, increasing the amount of anxiety, depressive symptoms, and burnout [17]. Men in this age group are particularly prone to engage in substance abuse and self-harm because these men are in a very high risk of suicide, which need specific focus at this [2]. The stigma attached to someone who suffers from mental health issues is one of the main barriers to men treating mental health issues. Most men tend to subscribe to the social narrative that being in a vulnerable situation or expressing emotional pain is a weakness and for this reason they do not seek help [28].

Midlife Crisis of Men

The "midlife crisis" is related to the men of their middle age in between 40 and 65 years, signifying a phase of psychological and existential contemplation. This transitional period can trigger various mental health problems including mortality, questioning life purpose and achievements, role changes and identification of new problems [28]. The midlife crisis is associated with emotional dissatisfaction, agitation, and elevated risk taking behaviour and is generally paired with increased depressive symptoms. More importantly, the phenomenon is not at all homogeneous; there is a lot of variability both on the individual level, and through social determinants in the way the latter is manifested, and in its consequences for mental health [33]. Among men, a prominent dimension has been an enhanced sense of vulnerability and an attempt at recuperating youthful energy and vitality, a cyclic process, which can result in new explorations or important life changes, such as taking up new interests, changing career paths, or engaging in extramarital activities as men struggle to accept the reality of ageing and the assumption that their youthful vitality can be reduced [3]. Another dimension is the assessment of the men's own accomplishments and aspirations, a lack of fulfillment is often revealed as the outcome of the impingement of the social and within person ideals. This can cause low self-esteem, loss of confidence and severe self-doubt about the meaning of life [31]. Many of these problems are accompanied by social expectations for a man to be a successful professional, be a good provider and ensure success in fulfilling all of his family's needs [15].

Characteristics of Midlife Crisis of Men

The midlife crisis offers a unique combination of a biological and psychosocial phenomenon. It has a very different sort of expression and impact on mental health in different people. Findings of psychological studies have revealed that men are particularly vulnerable to emotional and psychological distress during the time of transition [2] [9] [15].

The existence of the following indicators is not a prerequisite for the crisis; nevertheless their detection allows access to the system of support at a sufficient level, which will help the individuals and their close ones to cope with the related problems successfully. But since the experiences vary greatly across the individuals, the simple fact that these indicators occurred does not necessarily indicate with unequivocal certainty that a crisis exists. Drawing upon the existing literature and psychological perspectives, some major characteristics of the midlife crisis among men are

Emotional and Psychological Shifts:

Existential Questioning: Men undergo an examination of their life's purpose, meaning, and achievements on deeper levels [8]. Many of them struggle with the contemplation of their mortality, legacy, and what do they intend to accomplish throughout the rest of their lives. They can experience self-identity and self-perception conflicts when shifting to midlife years with role and identity transition like financial provider to have a more balanced life, or parent to an empty-nester [7]. These emotions can be symptomatic of a sense of self-doubt and result in feelings of anger, depression, and a lack of confidence in their personal worth and their professional success.

Restlessness and Dissatisfaction: The midlife period is characterized by an increased dissatisfaction with an occupational or interpersonal sphere as reported by men characterized by a feeling of boredom, restlessness, and feelings of the unfulfilled desire of wanting more fulfilling experiences [17]. When some men want to break from mundane life and find new means to express their inner vitality or to overcome the perceived stagnation of the mid-adult period, they turn to some form of foolish or impulsive spending on extramarital affairs, dangerous hobbies, or radical lifestyle or occupational change transitions [21].At the same time, the emotional and mental changes that are behind this stage can trigger the depressive symptoms of persistent sadness, hopelessness, loss of motivation, and of a perceived diminishing purpose [4].

Increased Vulnerability and Emotional Sensitivity: During middle age, it is common to find men becoming extremely sensitive to their emotional vulnerability and becomes largely predisposed towards integrating themselves in their inner emotional lives in a more deep-rooted way [32]. These are the developments that break with the traditional masculine ideas that emphasise stoicism and repression of emotions [13]. Midlife therefore challenges men to re-examine their position in society, their relationship with other people and the demands that are placed on them during this passage through life [38].

Behaviour and Life Style Changes:

Impulsivity and Risk-taking Behaviour: During middle age, men have a high inclination to exhibit impulse and risky behaviours. Such behaviours can include spending money on a purely experimental basis, indulging in an unhealthy lifestyle such as hobbies that include extreme sports, taking up extra-marital affairs, or even quitting work without reason [6]. People with these habits usually do this for the sake of reliving their youthful zeal and energy. At the same time, men are likely to revisit long-held personal and professional aspirations, thereby changing lifestyles through, for example, career changes, returning to university, or an increased emphasis on leisure [23]. Further, individual midlife may result in renewed or totally new commitment to previously overlooked interests. Yet such compulsive patterns are exhibited alongside severe interpersonal conflict, particularly in the marital and family life, because the person is re-negotiating their sense of self and value system [20] [41]. Midlife crisis therefore has the capacity to give rise to significant stress in the family and marital life.

Social Withdrawal: During the middle age, social withdrawal is seen to be one of the coping styles embraced by some men. It is characterized by the lack of interest in the social and cared about activities, the desire to be alone, the conscious looking away from the contacts that were previously appreciated [9]. Some of the choices are related to the wish to get away from being judged, the feeling of incongruity, that it is time to reconfigure and live a new direction. This necessitates therefore, a subtle insight into the manner in which there are shifts in emotions, psychologically, and behaviourally in the context of this crucial phase towards adulthood in men [32].

Changes in the Appearances and Hobbies: Studies reported that men also tend to increase their engagement in physical exercise and diet restriction, in the attempt to influence their physical aspect and to portray youthfulness [11]. At the same time, some people may fail to observe grooming and hygiene or become involved in maladaptive responses, such as increased alcohol consumption or substance recreational use, to respond to perceiving the challenges in their middle age [19].

Relationship and Identity Changes:

Relationship Conflicts and Revaluation: In the modern context of relationships, men often cannot find appropriate ways to describe their emotional needs and subjective feelings, consequently causing misunderstanding, conflict between people, and social distance [12]. During the crisis period, men can engage in a serious re-evaluation of established relationships or marriages and desire to fulfil unfulfilled needs or to increase compatibility [41]. This reconstitution can place considerable strain on familial relationships, as families negotiate identities and values while in transition; affects and disturbances resulting from this often dominate situations within the home. Besides the intensive self-analysis related to roles, their accolades and life paths, these processes encourage most men to challenge the alignment of their present conditions with their former expectations and identifications as well as bring into existence discontentment and an experience of existential loss as well as a specific urge to locate new meanings and fulfilment.

Identity Shifts and Role Confusion: Male identity through the life course is characterised by renegotiation of male identity due to age related changes with occupational, family, and relationship statuses. The reappraisal might result in a new degree of role confusion or a reinforcement of the pressures of the self that provide new definitions of values, priorities and the relative importance of life spaces [14].In this regard, men can question values, priorities, and the importance of various spheres in life. The resulting temporality of soul searching can be an uneasy one as people strive to balance their contemporary view of the self with past experiences, and visions of the future. The midlife crisis, specifically, often leads to a very detailed examination of personal achievements, mistakes and the general course of the personal and career path of each individual, thus cultivating the desire to live in a more genuine and fulfilling way [15]. A deeper understanding of the multidimensional complexity of the midlife crisis in men thus requires a complex understanding of the emotional, psychological and behavioural changes that men go through with this turning point of life, as individuals struggle with changing identity, relationships and seeking fresh purpose and meaning [38]. Midlife transition represents a very important developmental phase for men and is characterised by increasing levels of reflection and has high probability of substantial amounts of emotional, behavioural and social disturbances. Among the more generally familiar signs and symptoms are disproportionate restlessness, dissatisfaction, existential questioning, changes in behaviour, and anomalous changes in relation to others and the self. Men are shown to be impulsive and take risks or become obsessed with regaining a young identity. Men navigating intimacy based on gender assumptions, construct agency, tackle identity formation and shifting needs and experience breakdowns in communication in heterosexual relationships.

Unpacking the Contributing Factors of Midlife Crisis among Men

The concept of the "midlife crisis" in men, though sometimes portrayed with light hearted stereotypes, reflects a period of profound transition and potential psychological turbulence for many individuals [5].Though it develops after 40 to 65, typically it is not brought on by a catalyst but develops as a cumulative construct, whereby individuals feel forced to demonstrate their identity by defining their place in the social order [26]. Though it is not possible to ensure that every man would face a well-developed midlife crisis, a more empathetic understanding of the antecedents would lead to personalisation, reflexive insight and effective coping patterns. Here are key elements that shed light on the complexities of the midlife crisis of men:

Hormonal Shifts: The decline in testosterone is a physiological trend associated with age and has a consequent effect on energy, mood, sex drive, and mental functions [14]. The resulting hormonal shift can contribute to the development of a sense of tiredness, restlessness, affective disturbance and loss of drive, resulting in a general feeling of malaise and dissatisfaction. Therefore, when negotiating such physiological rearrangement, men might easily find

it hard to maintain the same level of physical and psychological vitality that they had attained earlier, leading to a re-evaluation of the self-image, abilities, and well-being [13].

Physical Changes and Mortality Awareness: As men move through midlife, their physical reserves such as strength, stamina and resilience often become depleted [32]. This physiological shift combined with a susceptibility to age related ailments can bring about the realisation of mortality as an existential truth for each individual. As human beings have become conscious of their finite existence, they have become contemplative and reflective about the nature and value of life. The realisation that their physical abilities are diminishing leads men to re-evaluate their self-perception, capabilities, and overall well-being, as they grapple with the prospect of declining health and the inevitability of their own demise in the years to come.

Career Stagnation and Dissatisfaction: Many men reach a point in their professional trajectories where opportunities for advancement diminish or stall, resulting in feelings of staleness, monotony, or a sense of lacking purpose [21]. This can be compounded by the realization that they may not achieve their previously held ambitions which can lead to disappointment and a search for meaning again. As they confront the reality that their career progression has plateaued, men may experience a profound sense of unfulfillment, prompting them to re-evaluate the direction of their professional lives and seek alternative avenues to find greater significance and fulfilment.

Financial Pressures and responsibilities: During this midlife transition, men often deal with increasing money obligations such as paying for a home, funding children's school education or having to care for elderly parents. This added financial strain, coupled with concerns about not being able to save enough for retirement, can contribute to high levels of stress and feelings of constraint or being overwhelmed. This heavy load of costs, coupled with worries about our uncertain future, might make men feel trapped and doubt their ability to adequately support themselves and their dependents in the long run.

Relationship Challenges and Evolving Needs: Relationship difficulties experienced by couples as they move through midlife typically reflect struggle to deal with changing life stages and needs and with the management of unresolved interpersonal issues [12]. During this time men can feel disconnected, isolated, or a desire for deeper intimacy, and emotional closeness. Adjusting to the new roles that they are adopting at times and the ever changing nature in their relationships can be hard for men and manifest in a sense of separation and an enhanced desire for greater emotional satisfaction in their relationships.

Parenting Demands and Empty Nest Syndrome: As their offspring mature and attain greater independence, men may confront a sense of loss and a shift in their parental role [22]. The struggles in keeping a close, meaningful relationship with now-grown kids can be huge. The shift away from nurture-mode to an empty nest can trigger feelings of emptiness, irrelevance or the desire for a more central and influential role in their children's lives. This can be a difficult adjustment for men, as their role as parents plays a significant part in their own sense of purpose and fulfilment. During the midlife span, this new paradigm change in the family system may be a profound source of emotional distress and inflicts pain on individuals.

Social Comparisons and Cultural Expectations: Men are always considered in the society to be successful, youthful, and masculine [25].With the advent of social media, these expectations are even higher as men must compare themselves against idealised pictures and stories of their companions or peers. The struggle to meet these standards can lead to deep feelings of inadequacy. While dealing with these social expectations, certain men may attempt to reclaim their lost youth or test their masculinity through outward expressions of wealth, status, and power. The need for validation can deeply impact the male midlife crisis since many men do not feel that they have reached the desired benchmarks or achieved their self-projected goals.

Unresolved Childhood Issues and Traumas: During the middle age, repressed feelings or unprocessed childhood trauma from the past can emerge as a need for self-reflection and healing [34].These feelings can include feelings of

hopelessness, anxiety, and depression, as well as having unhealthy coping mechanisms. When confronted with these deep-seated issues from the past, men may feel compelled to embark on a journey of self-reflection and personal growth in order to overcome the lingering effects of their childhood experiences and attain a greater sense of wholeness and emotional well-being

Lack of Purpose and Meaning: Without a clear sense of meaning or purpose in life, men can feel aimless, unfulfilled, and unsure of what they are doing or where they are headed in their lives [8].This can prompt them to embark on a quest for novel passions, hobbies, or spiritual endeavours in an effort to regain a sense of purpose and achieve greater fulfilment. As they navigate this midlife transition, men may feel compelled to redefine their goals, values, and the fundamental elements that lend meaning to their lives, in order to overcome the pervasive sentiments of listlessness and dissatisfaction that can characterise this period.

Midlife Crisis of Men: A Silent Crisis in Mental Health

The stage in a man's life known as the midlife transition entails a period of high sensitivity that can potentially develop into a worldwide health menace. This stage of life, usually ranging from the ages of 40 to 65, involves the sharp intersection of biological, psychological, and social processes which negatively affect men's mental, physical, and social health [13].During this time, it is important to know the plight of men and why they delay seeking help. Failing to do so does not only add to the stigma, but also prevents the creation of adequate solutions and support.

The Mental Health Burden

Men are at an increased risk of developing a number of mental health issues during midlife. The decreasing levels of testosterone along with stressors in life and society can lead one towards depression, anxiety, anger, and drug addiction [14].In addition, stigma regarding mental health in males, which results from traditional roles for males in reinforcing the association of emotions with weakness, prevents most males from seeking help [25].The combination of these obstacles can lead to a greater chance of sufferers remaining silent and leaning towards unhealthy coping strategies that worsen the situation and heighten the issues with mental health below:

Depression and Anxiety: Men in midlife often experience a convergence of stressors, including career plateaus, financial anxieties, relationship challenges, and a sense of lost purpose [21]. With the superimposed changes in hormones, this may exponentially increase the likelihood of the onset of feeling anxious and depressed. The social demand for men to be unemotional providers creates barriers towards accepting and seeking help.

Substance Abuse: Men are trying to deal with the impact that midlife crisis has on emotions, and addiction to some sort of drugs and alcohol appears to be their solution for evading problems [6].The resulting effects can aggravate the pre-existing mental as well as physical health challenges, leading to a spiral of addiction, which ultimately affects families and communities.

Suicide: During middle age, men seem to be more inclined towards suicide when compared to others age groups. This alarming figure shows how repressed the conversation can be around the subject of men and depression, and how little progress or acknowledgement there has been in addressing the facts or driving forces behind it [18]. This information is alarming but it sheds light to a mental health issue that mid aged men face, which causes them to resort to such acts, showing the need for more preventive measures and proper guiding and aiding services available to them.

Relationship Issues: The midlife period is often accompanied by substantial stressors on personal relationships, such as heightened career obligations, financial anxieties, and the demands of raising children. The symptoms of the midlife crisis include irritability, emotional withdrawal, and/or poor behaviour among men, which can eventually become a source of strain in relationships with one's spouse, partner, and children[16].This can lead to heightened conflict, communication problems, separation, and divorce, which is bad for family structures and wellbeing [34].

Social Isolation: Men in the midlife stage may become withdrawn from their regular social interactions, recreational activities, and support systems [12].This self-imposed social withdrawal can intensify their existing mental health problems like depression and anxiety, initiating a detrimental cycle where the retreat from social ties further compounds their emotional turmoil. As a result, it becomes increasingly difficult for these men to obtain help or to use healthy coping strategies that might otherwise help them get through this transitional period.

Intergenerational Effects: Children of fathers experience many relational, emotional and behavioural problems that may follow these individuals into adulthood. These children are affected profoundly especially when they see their fathers battling with mental illness, relationship issues, and substance abuse, which could ultimately affect their future relationships. They can have trouble developing healthy coping skills, have healthy and nurturing partner relationships, and transition through their own lives with confidence and resilience [8].

Physical Health Implications:

Psychological and emotional burdens from a midlife crisis bear negative consequences on a man's physical health. Chronic stress in response to high intake of carbohydrates and fats in the diet, insufficient physical exercise, or use of drugs can have negative effects on a person's health, and are mentioned below.

Cardiovascular Diseases: According to Evans *et al*. (2011), high concentrations of the stress hormone cortisol and the high blood pressure and inflammation result in heart disease. Given that men already face the highest probability of heart-related sicknesses, the psychological issues surrounding the midlife crisis escalate these chances. This then causes a further increase in heart attacks, strokes, and many other complications.

Weakened Immune System: Chronic stress reduces the immunity indiscriminately and consequently it means that men who are under stressed in chronic condition are susceptible for getting the infection [33]. It is this condition that creates the vicious circle of physical challenges being linked to issues with one's mental health, which leads to further stress, and eventually the total downfall of the individual's life.

Sleep Disturbances: Anxiety and depression are arguably the most common conditions one can suffer from during midlife and its associated problems. It's definitely a contributing risk-factor, especially when it's mixed in with sleep problems. A range of sleep disturbances are associated with sedation, reduced alertness, increased risk of errors and accidents, increased agitation, impaired concentration and activity [32]. On top of this, consistently poor sleep leads to a multitude of other severe medical issues like heart disease, diabetes and obesity.

Economic Implications:

The economic consequences of unaddressed midlife crisis in men are significant and far-reaching, impacting not only the individuals themselves but also their families, communities, and national economies some of the factors are discussed below:

Low Productivity at Workplace: Mental and physical health issues related to midlife crisis can result in reduced concentration, motivation, and performance at the workplace [35]. This can result in absenteeism, loss of productivity, increased errors, missed deadlines which eventually leads to job performance and career growth.

Heightened Healthcare Expenditure: Untreated mental and physical health issues contribute to greater healthcare utilisation and costs [39]. This is putting a strain on individuals, families and health systems, as men going through midlife crisis often need more frequent medical visits, medication, therapy or even hospitalisation.

Strain on Welfare Systems: Unemployment, disability (physical/mental), substance abuse can cause increased strain on social welfare programs and strain on government [24]. This reflects the economic cost of failing to deal with midlife crisis to society.

Loss of Human Capital: Loss of human capital occurs through serious health or social problems affecting men in their peak working age, as these men are unable to access the benefits of further contributions to the economy, society, and national growth [21]. This loss of human capital can have a long-term impact on economic growth and innovation.

Diminished Economic Growth: When people continue to experience unresolved issues during their middle age, their overall productivity, innovation, and economic growth can be negatively affected [40]. When such a significant percentage of workers are affected by health problems, relationship turmoil, or substance abuse, it will inevitably affect national productivity and the country's economic performance. The impact of unaddressed midlife crisis for men stretches much beyond the individual and imposes a great burden on healthcare systems across the world. Men suffering from these crisis have a higher likelihood to seek regular hospital visits, emergency services and long-term care for chronic conditions, driving up the costs of healthcare and increasing the impact on available resources [39].The increased prevalence of chronic diseases such as cardiovascular disease, diabetes and mental health disorders that come with midlife crisis also translates to greater demand for on-going medical care and long-term care, overloading healthcare systems that are already working under strain from increasing costs and ageing populations.

Addressing Midlife Crisis among Men: A Critical Psychosocial Concern in Contemporary Society

While there has been tremendous progress in global health efforts to combat infectious diseases and to improve women's and children's health, the distinct health needs of men, especially during midlife, have been almost completely neglected. The reason for this omission is not only a matter of gender justice, but also a public health concern with far reaching social and economic implications. However, incorporation of the male midlife crisis into global health policy frameworks needs to be taken to reduce this silent crisis and improve the overall health of the men, his families and communities across the world. The tendency toward men's health issues being overlooked is in part due to the classic view of men to be inherently strong and less prone to health issues. In addition, the expectation that men are supposed to be emotionally unresponsive creators in society often becomes a deterrent factor that prevents them from having the need to accept help and reveal their vulnerabilities [40]. As such, men are less likely to be involved in preventative health care activities, report health problems and seek timely medical treatment resulting in later stages of disease and poorer health outcomes [1]. The midlife transition is a time of increased vulnerability for men, a time when biological, psychological and social stresses converge. That lower testosterone level and the fact that men feel they don't have enough time for family, career, etc. can lead to a range of psychological problems, such as depression, anxiety, substance abuse, and more [32]. Insufficient treatment due to stigmatisation and unsupportive contexts may adversely affect physical health, such as increased risk of cardiovascular disease, suicide and premature death [6]. Thus ignoring the male midlife crisis not only has implications for men's health, but also for broader social and economic consequences. Stress-related problems, reduced productivity, and rising healthcare costs are just a few of the ripple effects that spread out from the individual to the family, to the community, and of course, to national economies [39].Several key strategies can be implemented to effectively address the male midlife crisis within global health policy frameworks:

Raising Awareness and Reducing Stigma: Public health programmes can be implemented to help rebalance masculine gender stereotypes and encourage men to take better care of their own well-being. Communication around mental health and help seeking needs to be opened up. This includes challenging the myth of invincibility in men and making them less likely to suffer from health problems and creating a more supportive environment in which men feel entitled to express their vulnerabilities without fear of stigma or judgement.

Integrating Men's Health into Existing Initiatives: Health programmes and strategies for non-communicable diseases, mental health and drug/alcohol abuse, should have a gender-sensitive approach to ensure that the specific needs of men are taken into consideration. This may require modifying programme content, delivery mechanisms and outreach techniques to make them more relevant to males and more responsive to their needs.

Developing Targeted Interventions: It is important to develop culturally appropriate men's programmes that address men's preferences and life experiences. This can include ensuring that mental health services are available and accessible, encouraging healthy lifestyle choices, and providing support for men who may be struggling with work life balance and relationship dynamics. Any such intervention should be informed by a robust understanding of the specific stressors and demands of men going through the midlife transition, including the time of decreased testosterone production, career pressures and family responsibilities.

Investing in Research and Longitudinal Studies: In order to understand the multi-faceted factors contributing to male midlife crisis, it is essential to engage in research and longitudinal studies that shed light on these dynamics in various cultural contexts. Gathering gender disaggregated data on men's health indicators is an important step in developing effective policies and interventions. This research should be conducted to identify the biological, psychological and social causes of the midlife crisis, and the long-term effects of the experience on the individual, family and society.

Culturally Sensitive Practices: The midlife crisis among men presents itself in unique cultural ways in terms of how it manifests and is experienced, influenced by societal norms and expectations and the structures available to support someone through this challenging period. Cultural backgrounds play a large role in the way men experience and express their emotions, their willingness to seek help, and their preferred ways of coping. Translation from one language to another, superficial adaptation of a practice or protocol, does not meet the international standards for culturally relevant practise, which involves a deep understanding of and respect for the values, beliefs and traditions of various cultural groups leading not only to improved health equity on an individual basis, but also toward better communities.

CONCLUSION

Despite popular culture trivializing the midlife crisis as an inevitable and universal rite of passage for men, it remains an urgent psychosocial issue that warrants increased scholarly and clinical attention. Midlife is not just a chronological period but a phase that is marked by psychological struggles, changing family responsibilities, changing social roles and increased awareness of bodily and existential limitations. This can be a confusing phase for men, and one that has been characterised by questioning of identity, stagnation in work life, and problems with relationships with others, which, if not adequately provided for, can leave men exposed to the emotional distress. A psychosocial approach claims that the midlife crisis is neither an individual weakness nor a cultural cliche but a symptom of the underlying crisis associated with masculine social expectations, unrealized dreams, and a lack of available structural resources for mental health care. Years of neglect in the research and practice of this issue, has left men's midlife vulnerabilities largely invisible and untreated so that early intervention and prevention efforts have been lost. The complexity of this issue creates the need for interventions at multiple levels from the individual to the individual's institution to the society. Mental health interventions (general practice based interventions, family based interventions and targeted interventions) as one of the core elements of resilience building Policy frameworks should adequately identify midlife well-being as a mental health concern and promote the integration of wellbeing, awareness, screening, and intervention resources. Both an ethical imperative and a clinical necessity are to frame midlife crisis among men as a legitimate mental health concern. With more understanding and positive action, this moment of crisis can be a time of opportunity, when men can emerge from the struggle stronger, less-inflammatory, more resilient, better connected, and more meaningful and fulfilling lives.

ABSTRACT

The infusion of digital instruments in farming is crucial for productivity and sustainability improvement, especially among smallholder farmers. Nonetheless, empirical research that connects digital farm management (DFM) utilization to managerial effectiveness and optimization of resources in the context of rural South India remains limited. The research explores the adoption levels, drivers, and effectiveness of DFM tools on managerial effectiveness and sustainable practices among smallholder farmers in Coimbatore, Tamil Nadu. A mixed-methods strategy was utilized. Quantitative information was gathered through a standardized questionnaire from 200 smallholder farmers who were selected by stratified random sampling across four major agricultural villages in Coimbatore district. Technical efficiency scores were calculated using Data Envelopment Analysis (DEA). A multiple regression model determined the effect of DFM adoption on productivity and profitability, whereas a logit model determined the principal determinants of adoption. Qualitative details from 15 in-depth interviews complemented the quantitative results. The rate of adoption of DFM tools was 42%. DEA results showed that adopters had a technical efficiency mean score of 0.89, which was significantly higher ($p<0.01$) than 0.72 for non-adopters. Regression analysis supported a positive and significant correlation between crop yield ($\beta = 0.18$, $p<0.01$) and net income ($\beta = 0.15$, $p<0.05$) with DFM adoption. The major constraints were

low digital literacy, high cost perception, and poor internet connectivity. DFM tools greatly improve managerial effectiveness and encourage efficient use of resources among smallholder farmers. The evidence suggests that focused interventions with emphasis on skill building, infrastructure development, and finance are the key to increasing adoption at scale. The research adds to existing literature by offering a strong, empirical connection between digital technology, management practices, and farm sustainability.

Keywords: Digital Agriculture, Managerial Efficiency, Data Envelopment Analysis, Smallholder Farmers, Sustainable Resource Allocation, Technology Adoption, India.

INTRODUCTION

The Indian agriculture sector, though the backbone of the economy, continues to suffer from ongoing issues of farm size decline, degradation of resources, and climatic variability. Sustainable productivity improvement is essential for the purpose of ensuring food security and farmers' livelihoods, particularly of the majority of small and marginal holders (Birthal, Roy, & Negi, 2015). Here, Digital Farm Management (DFM) in the form of mobile-based advisory services, sensor-based irrigation, and farm management software comes as a game-changing strategy to maximize decision-making and utilization of resources (World Bank, 2019). The Coimbatore district of Tamil Nadu is a microcosm of these challenges and opportunities. Being the leading horticultural and cash crop-producing district, farmers of the region have water scarcity and input price inflation problems. Though a number of DFM programs have been launched by government and private organizations, their penetration among smallholders is below par (National Bank for Agriculture and Rural Development [NABARD], 2021). The current narrative tends to place emphasis on availability of technology, but there is a missing link in how it is brought about in conjunction with fundamental managerial tasks of the farmer, including planning, resource allocation, and control (Klerkx, Jakku, & Labarthe, 2019).

This research, thus, argues that the real contribution of DFM is not so much in adoption but in enhancing managerial efficiency. By managerial efficiency in agriculture, we mean the farmer's capacity to derive maximum output (yield, profit) from a specified set of inputs (land, water, fertilizer, labor) through optimal planning and implementation. The main research issue is low usage of DFM tools resulting in inefficient use of resources and lower farm productivity for rural Coimbatore smallholders. This study attempts to fill this knowledge gap by empirically examining: (1) the extent and determinants of the adoption of DFM, (2) its causal effects on managerial productivity and farm performance, and (3) the socio-economic and infrastructural factors that limit its adoption. The results provide policy-relevant evidence to guide policymakers, extension services, and agribusinesses to craft effective strategies to promote digitally-enabled, sustainable agriculture and farm management.

LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

The Evolution and Potential of Digital Farm Management

Digital technology in agriculture has developed from basic decision support systems to comprehensive platforms transforming farm management. Initial research concentrated on the use of Information and Communication Technologies (ICTs) like mobile phones to deliver market information, cutting the costs of transactions and information asymmetry (Aker, 2011). The paradigm has now moved to Precision Agriculture (PA) and DFM that utilize technologies such as GPS, sensors, and data analytics for spatial and temporal variability in managing resources (Aubert, Schroeder, &Grimaudo, 2012; Wolfert, Ge, Verdouw, & Bogaardt, 2017). The theoretical potential of DFM is its ability to reduce risk and maximize production. For example, real-time weather information and forecast models can be used to guide irrigation and pesticide use, making farming less susceptible to climatic shocks

(Tanti & Jha, 2020). Soil moisture sensors enable accurate irrigation, saving water and enhancing water-use efficiency—a vital issue in water-scarce states such as Tamil Nadu (Gautam & Singh, 2021). Economically, DFM is argued to shift farm management from a tradition-based activity to a data-based activity, with potential to result in substantial productivity and profitability gains (Schimmelpfennig, 2016).

Managerial Efficiency in Smallholder Agricultural Systems

Managerial efficiency in agricultural economics is a broad concept generally dissected into technical efficiency (obtaining maximum output from a fixed combination of inputs) and allocative efficiency (utilizing the inputs in their best possible proportions relative to their prices) (Coelli, Rao, O'Donnell, & Battese, 2005). Measuring technical efficiency through generally non-parametric methods such as Data Envelopment Analysis (DEA) gives a firm measure to compare farm performance. Determinants of managerial effectiveness are well-established. Farm-specific attributes like education, experience, and risk tolerance are of particular significance (Bridle, Magrath, & Davies, 2018). External determinants like access to credit, extension services, and land security are also highly relevant (Mwangi & Kariuki, 2015). Yet the literature has classically viewed technology as one of a range of inputs, not as an underlying facilitator that changes the very process of management.

Closing the Gap and Formulation of Hypothesis

A systematic review brings forth a clear gap. As there is a large volume of literature on the uptake of single technologies and another one concerning the determinants of farm efficiency, few studies have put them together in order to explore how DFM tools actually enrich the managerial capacity of smallholder farmers (Klerkx et al., 2019). This research attempts to fill this gap by suggesting that DFM tools facilitate a mediator that increases the farmer's ability to perform core managerial functions.

According to this framework, the following hypotheses are developed:

H1: Farmers utilizing DFM tools exhibit a much higher degree of technical efficiency in the utilization of resources than non-adopters.

H2: DFM tool adoption has a significant and positive effect on farm profitability and crop productivity.

H3: DFM adoption is likely to be fostered through the level of education of the farmer, digital literacy, and the availability of good information.

METHODOLOGY

Research Design and Study Area

The researcher used a sequential mixed-methods research design (Creswell & Plano Clark, 2017). The research was carried out in four purposively chosen blocks of Coimbatore district—Karamadai, Thondamuthur, Anaimalai, and Pollachi—to reflect agricultural diversity.

Sample Size and Sampling

The population of interest was smallholder farmers farming on less than 2 hectares of land. Two-stage stratified random sampling method was used. A sample of 200 farmers was obtained. In the qualitative stage, 15 farmers and 5 key informants were selected purposively.

Data Collection and Variables

Data were gathered from January to March 2023 using a structured questionnaire.

Dependent Variables: Technical Efficiency Score (DEA), Farm Productivity (kg/ha), Farm Profitability (Net Income/ha).

Independent Variable: DFM Adoption (Binary: Yes/No).

Control Variables: Age, Education, Farm Size, Digital Literacy (5-point Likert scale).

Analytical Techniques

Data Envelopment Analysis (DEA): An input-oriented DEA model under variable returns to scale (VRS) was employed to estimate technical efficiency scores.

Econometric Models: Multiple Linear Regression (for H2) and Binary Logit Model (for H3).

Thematic Analysis: For qualitative data (Braun & Clarke, 2006).

RESULTS

Descriptive Statistics and Adoption Profile

Of the 200 farmers, 84 (42%) were DFM tool adopters. Adopters were significantly younger (mean age 38.7 vs. 51.2 years; $p<.01$) and more formally educated (12.4 vs. 8.9 years; $p<.05$) than non-adopters. The most frequently utilized tools were weather apps (68% of adopters) and irrigation schedulers (45%).

Hypothesis Testing

H1: Effect on Managerial Efficiency. The DEA findings reinforced H1. The technical efficiency average score for adopters was 0.89 (SD=0.08), which was considerably greater ($t(198)=5.82$, $p<0.001$) than the average score of 0.72 (SD=0.12) for non-adopters.

H2: Effect on Productivity and Profitability. The regression analysis with controls for farm size and experience supported H2. Adoption of DFM significantly affected yield ($\beta=0.18$, $p<0.01$) and net income ($\beta=0.15$, $p<0.05$). Results are presented in Table 1.

H3: Adoption Determinants. The results of the logit model confirmed H3. Education (OR=1.32, $p<0.05$), Digital Literacy (OR=2.15, $p<0.01$), and Internet Access (OR=1.87, $p<0.05$) were the significant determinants. Farm size was not significant (OR=1.08, $p=0.55$).

Qualitative Results: Adoption Barriers

Thematic coding revealed three main barriers:

Technological: "The internet connection is very weak here; the app does not load when I need it most." (Farmer, Thondamuthur).

Financial: "The drip system sensor is more expensive than my one season profit. How can I manage to pay?" (Farmer, Karamadai).

Human: "I don't feel free using smartphones. I have to depend on my son, but he is in the city." (Farmer, Anaimalai).

DISCUSSION

This research yields empirical confirmation that the adoption of DFM substantially improves managerial effectiveness and economic performance for smallholders. The 17-percentage-point technical efficiency gap between adopters and non-adopters indicates the potential for digital technology to revolutionize resource optimization, corroborating findings by Coelli et al. (2005) and Pierpaoli, Carli, Pignatti, and Canavari (2013). The equitable effect on yield and income (H2) is consistent with the theoretical potential of DFM as a risk-reducing and optimisation tool (Aubert et al., 2012; Schimmelpfennig, 2016). Qualitative results illustrate depth in our knowledge of the adoption paradox: while obvious advantages exist, adoption occurs against a background of sophisticated infrastructure, cost, and skill barriers, a pattern identified elsewhere in developing situations by Klerkx et al. (2019). The inability of farm size to be a good predictor of adoption (H3) contradicts the general misconception that it's only larger farms that can gain from digitalization. This indicates that smallholders, as well, can be effective users of technology using proper and scalable solutions, an important finding for policymakers.

CONCLUSION AND IMPLICATIONS

This work adds to the literature base by empirically connecting Digital Farm Management (DFM) adoption to core management science concepts like technical efficiency, and offering a field-tested model of how technology affects management and performance in smallholder agriculture. Practically speaking, closing the digital divide in agriculture means addressing it through a multi-disciplinary approach. This starts with facilitative policies that invest in rural digital infrastructure and mainstream DFM training within public extension systems. At the same time, the agribusiness industry needs to react by developing low-cost, vernacular, and offline-first DFM solutions specific to the complex needs of smallholders. At the level of practice, adoption can be facilitated further through collective action spearheaded by Farmer Producer Organizations (FPOs), which assist in lowering costs to the individual and provide a supportive framework for technology use.

Limitations and Future Research

Cross-sectional design restricts causal inference. Future studies should utilize longitudinal designs and investigate the effect of individual DFM tools on environmental sustainability measures.

ABSTRACT

Hydroxyapatite (HAP) [$Ca_{10}(PO_4)_6(OH)_2$] is a bio ceramic material for artificial bone substitution in biomedical applications due to its chemical composition and crystallographic structure closely resembling that of natural bone and dental tissues. This study presents the synthesis and characterization of a novel hydroxyapatite (HAP)assisted with proline and polyvinylidene fluoride (PVDF), synthesized via a facile hydrothermal method. A flexible fluoropolymer known for its chemical stability, biocompatibility, and piezoelectric qualities, polyvinylidene fluoride (PVDF) holds great promise for use in biomedical applications. Proline, an amino acid that is well-known for its function in tissue repair and biocompatibility. By combining proline's biological compatibility with PVDF enhances the development of HAP.The obtained nano powders were characterised by analytical methods. X-ray diffraction (XRD) results revealed the crystallite size, Fourier transform infrared spectroscopy (FTIR) affirms the purity of the sample by confirming the functional groups of the hydroxyapatite while scanning electron microscopy (SEM) displays the spherical morphology of the composites, Thermogravimetric analysis (TGA) was to ascertain the thermal stability. The cell viability (MTT assay) studies were conducted to ascertain the biocompatibility of the nano HAP powders. The findings show that these composites have enhanced bioactivity and cell adhesion, which are promising properties for use in bone tissue engineering. This study identifies areas for additional research to maximize proline integration while

highlighting the potential of proline-functionalized PVDF-HAP composites as cutting-edge biomaterials for orthopaedic and dental applications.

Keywords: Hydroxyapatite, Proline, Polyvinylidene fluoride (PVDF), Biocompatible, Biomedical applications.

INTRODUCTION

Hydroxyapatite (HAP), chemically represented as $Ca_{10}(PO_4)_6(OH)_2$, is a naturally occurring biomineral known for its excellent biocompatibility and bioactivity. It has been widely utilized in various clinical applications, particularly as a material for bone and dental implants, due to its chemical similarity to the mineral component of human hard tissues. [1-3] HAP has attained considerable attention owing to its outstanding biocompatibility, pronounced bioactivity, and capacity to establish chemical bonds with living tissues[4]. Functionalization of hydroxyapatite (HAP) nanoparticles with amino acids induces synergistic enhancements in their structural integrity, morphological features, and surface characteristics. Hydroxyapatite (HAP) with amino acids has been shown to enhance its protein adsorption capacity [5]. The bioactivity of nanoparticles such as hydroxyapatite (HAP) can be effectively enhanced and tailored through surface functionalization with water-soluble biomolecules. Among these, amino acids serve as promising candidates for the fabrication of bio-inorganic HAP nanoparticles and bio-nanocomposites, owing to their low cost, inherent biocompatibility, and strong affinity for interacting with HAP surfaces [6]. Furthermore, adding proline—an amino acid essential to collagen synthesis to HAP-PVDF composites provides a special method of improving biocompatibility and bio functionality. In order to manufacture HAP with the appropriate chemical and physical properties, a great deal of research is being conducted. Several methods for creating HAP are used, which include sol-gel [7], precipitation [8], hydrothermal [9,10], and biomimetic deposition [11] microemulsion [12,13] microwave method, [14,15] Recently, there has been an attempt to synthesize nanohydroxyapatite particles using an ultrasonic linked sol-gel technique [16]. Although morphology and particle size control are necessary for wet techniques, low-crystalline HAP may occur as a result of the processes' low temperature [17]. Because of its high temperature and pressure, the hydrothermal technique can enhance the crystallinity of HAP in comparison to the sol-gel and precipitation approaches [18]. Furthermore, additives make it simple to regulate the size and shape of crystals as well as the ideal temperature and duration for hydrothermal synthesis. Moreover, additives make it simple to regulate the size and shape of nanoparticles as well as the ideal temperature and duration for hydrothermal synthesis. Proline is a useful ingredient in the formation of sophisticated biomaterials because it supports the stability of protein structures and has the ability to enhance cell adhesion and proliferation [19]. Because of its flexibility and chemical stability, polyvinylidene fluoride (PVDF), a biocompatible polymer, is a desirable matrix material that can encourage tissue regeneration and cellular responses[20]. Proline and PVDF-based hydroxyapatite composites are being developed with the goal of combining the biological functionality of proline, and benefits of PVDF, and the bioactivity of HAP in a way that works well together to produce a material that can be used in biomedical applications like tissue engineering constructs, dental implants, and bone scaffolds. By combining these components, it is possible to develop a composite, biocompatible, and bioactive qualities for use in bone regeneration and repair. The goal of this study is to build and characterize hydroxyapatite composites based on proline and PVDF in order to produce a novel biomaterial with applications in biomedicine. In order to further the use of these composites in bone tissue engineering and other biomedical sectors, the study examines their production, biocompatibility, and bioactivity.

Experimental methods

Chemicals and Reagents

For the development of nano HAP powders, the chemicals utilized were calcium nitrate Ca $(NO_3)_2.4H_2O$(99.0%). diammonium hydrogen phosphate $(NH_4)_2{\cdot}HPO_4$, (98.5%) L-Proline (98%) and Polyvinylidene fluoride (PVDF) (99.8%).procured from Merck, India and L-Proline was procured from Avra, India All the chemicals utilized were of

analar quality and employed without additional purification. Double-distilled water and dimethylformamide (DMF) served as solvents in the process. Scheme 1. Flow chart of HAP synthesis with Proline and PVDF.

Hydroxyapatite Powder Synthesis

In a standard experiment, 0.04 M calcium nitrate was dissolved in double distilled water, and 0.024 M diammonium hydrogen phosphate was included under continuous mechanical stirring to achieve a 1.67 Ca/P ratio. Water was employed to dissolve Proline, while dimethylformamide (DMF) was utilized for dissolving polyvinylidene fluoride (PVDF), and ammonia was added to maintain the pH at 10. The mixture of calcium phosphate precursors and additions was agitated vigorously for one hour at 600 rpm with a mechanical stirrer. The reaction mixture Proline and PVDF dispersion and calcium phosphate solution were then put into a Teflon-lined autoclave and heated to 80 °C for three hours. To make sure, the elimination that potential contaminants, the precipitate was then separated by centrifugation and then washed with a 1:1 solution of water and ethanol. To synthesise pure nano-HAP powders, the precipitate was lastly dried in an oven, allowed to calcinate for two hours, and then sintered for four hours at 800 °C.

Characterization

The crystalline structure and phase purity of the as-synthesised nano-HAP powders were examined using a Bruker X-Ray diffraction (XRD) spectrometer. The samples were scanned in the 10-80° 2θ range. The Debye-Scherrer equation was used to determine the average crystallite size. In order to verify the presence of functional groups, specifically phosphate and hydroxyl groups in calcium phosphate, Fourier Transform Infra-Red Spectroscopy (FTIR) spectra of the samples were acquired using a Perkin Elmer spectrum (India). FTIR spectra were recorded in the range of 4000 to 400 $^{cm-1}$ at a resolution of 4 $^{cm-1}$. The size and shape of the nano-HAP powder were examined using scanning electron microscopy (A Carl Zeiss EVO 18), and TG/DTA (SDT Q600) was used to evaluate the thermal stability. It was used to record the weight loss as a function of temperature up to 900°C at a heating rate of 10°C per minute. TEM (FEI Tecnai G2 20 S-TWIN) was used to verify the formation of spherical-shaped nano-HAP powders in order to verify the structure and composition. The National Centre for Cell Sciences in Pune (NCCS) provided the MG 63 cell line. To assess the biocompatibility of the produced HAP powders, the cells were kept in DMEM supplemented with 10% FBS, penicillin (100 U/ml), and streptomycin (100 µg/ml) at 37 °C in a humidified environment with 50 µg/ml CO_2.

RESULTS AND DISCUSSION

X -Ray Diffraction analysis

XRD is used to determine the crystalline phases, crystallite size, and degree of crystallinity in synthesized hydroxyapatite composites. The produced hydroxyapatite with additives assistance is shown in the XRD spectrum in Fig. 1 (a–d).The successful formation of the apatite phase in all synthesized samples was confirmed by the presence of distinctive diffraction peaks that corresponded to the (002), (211), (112), (300), (202), (310), (222), (213), and (004) crystallographic planes are those of the spherical structure of HAP plane, respectively [21]. The remarkable crystallinity and phase purity of the hydroxyapatite crystals are further confirmed by the XRD spectra. Based on the standard international centre for diffraction data, it was found that the obtained hydroxyapatite powder is pure with a hexagonal phase. (ICDD) file number 09-0432 [22]. Fig. 1. XRD pattern of (a). HAP (b) 0.1 g Proline (c) 0.1 g Pro and 0.05 g PVDF (d) 0.2 g Proline and 0.2 g PVDF (e) 0.4 g Proline and 0.1 g PVDF The crystallite size of the nano powders was found in the range of 17 – 34 nm, evident from the crystallite size calculations carried out using Scherrer formula as shown in Table 1. $D = K\lambda / (\beta \cos \theta)$ where D = average crystallite size in nm, k = Scherrer constant, λ = wavelength of X-ray in nm, β = full width at half maximum in radians θ = Braggs angle in radians [23,24].Because of hydrogen bonding interactions between the carboxyl and amine groups of proline and the phosphate and hydroxyl groups of HAP, the addition of proline may cause a slight broadening of the HAP peaks, which indicates a smaller crystallite size. The biocompatibility of the composite is improved, but overall crystallinity may be decreased.he variations in the lattice parameters of the HAP crystals cause a small shift in the peaks.

Fourier Transform Infrared analysis

An effective analytical method for determining the molecular structures and functional groups in materials, including nanocomposites, is Fourier-transform infrared (FTIR) spectroscopy. The functional groups found in prepared nanocomposite powders sintered at 800°C were investigated in our study using FTIR. Each of the four samples' Fourier transform infrared (FTIR) spectra was noted and shown in Fig. 2 (a–d). The distinctive peaks in each spectrum attest to the production of hydroxyapatite (HAP). The symmetric stretching mode (v_1) of PO_4^{3-} group is represented by the absorption bands in the 940–965 cm^{-1} region. The v_3 asymmetric stretching mode of the PO_4^{3-} - is responsible for the strong absorption band seen at 1044 cm^{-1}. The v_4 asymmetric bending mode of the PO_4^{3-} is responsible for the absorption bands in the 604–574 cm^{-1} range. [25,26]. The v_2 symmetric bending mode of the phosphate groups is represented by the weak absorption band seen in the 473–425 cm^{-1} region. The stretching and bending modes of OH are linked to peaks at 3537 cm^{-1} and 628 cm^{-1}, respectively [27-29]. The hydroxyl (OH^-) groups' symmetric stretching vibration is represented by the band seen at 3550 cm^{-1}, groups inside the lattice of hydroxyapatite (HAP). The produced nano-HAP powder's purity is confirmed by the FT-IR spectra, which reveals no indications of impurities.

Scanning Electron Microscopic (SEM)Studies

The parameters involved in the hydrothermal synthesis method, including temperature, reaction duration, and concentration of reagents, play a crucial role in determining the particle size and morphology of hydroxyapatite (HAP) [30]. Consequently, SEM analysis was utilized to examine the morphological features of HAP before and after the incorporation of additives. Fig. 3 (a-d), illustrates the surface structure of the spherical hydroxyapatite powders made with the hydrothermal technique at different concentrations of proline and PVDF.0.1 g Proline, 0.1 g Proline and 0.05 g PVDF, 0.2 g Proline and 0.2 g PVDF and 0.4 g Proline and 0.1 g PVDF. Fig.3 (a) HAP sample consist of agglomerated nanohydroxyapatite powder, and the samples' dispersibility was enhanced through amino acid and polymer doping. In contrast to pure hydroxyapatite, hydroxyapatite infused with amino acids exhibits reduced particle size, improved dispersion, and compact grain size. The crystal boundary of pure hydroxyapatite is distinctly defined, and there is significant agglomeration, whereas the crystal boundary of hydroxyapatite modified with amino acid and PVDF doping is less distinct, suggesting a reduction in crystallinity for the samples with amino acids. This modification also leads to an improvement in dispersibility to a degree, and the samples exhibit a relatively larger specific surface area with a spherical morphology. Spherical shapes are especially beneficial for biomedical purposes, providing a greater surface area, better cell attachment, and superior drug delivery potential compared to irregular or rod-shaped forms[31,32]. The combination of HAP, proline, and PVDF in a spherical composite is anticipated to produce a material with enhanced characteristics for bone scaffolds and bioactive implants.

Transmission Electron Microscopy (TEM) Studies

Transmission Electron Microscopy was employed to examine the nanoscale structure, particle dimensions, crystallinity, and interfacial characteristics of hydroxyapatite (HAP) nanoparticles developed with proline and incorporated into a PVDF matrix, which was produced using a hydrothermal approach. It gives the structural and compositional attributes essential for the nanocomposite's uses in biomedical applications, micrographs showed that HAP nanoparticles had an elongated, spherical-like shape. The combination of hydrothermal synthesis and proline modification produced highly uniform nanoparticles that displayed less agglomeration. The interplanar spacings obtained from the selected area electron diffraction (SAED) rings align with the distinctive pattern of hydroxyapatite shown in Fig. 4 (b). The SAED patterns reveal only a broad, diffuse diffraction ring, suggesting an amorphous structural presence. Consequently, the synthesized powders exhibit exceptional crystallinity, as indicated by the SAED pattern displaying a regular arrangement of bright spots. The TEM and SAED images verify the creation of elongated- spherical HAP particles, measuring between 64 and 84 nm in size. These results underscore the nanocomposite's potential for use in bone tissue engineering and drug delivery

Thermal Analysis

Thermogravimetric analysis (TGA) was employed to assess the thermal stability and decomposition of hydrothermally synthesized nano hydroxyapatite powder using Proline and PVDF. The analysis was done in a

nitrogen atmosphere at room temperature and up to 900 °C, with a heating rate of 10°C/min. Fig. 5 (a–c) displays the thermogravimetric analysis (TGA) curves that were obtained for the prepared samples in the temperature range of 35–900 °C. TGA plots report the chemical breakdown or vaporization as well as the sample's thermal stability. The weight loss observed in the temperature range up to250 °C, is caused by adsorbed water and the elimination of lattice water in the HAP samples [33], and the resulting curves demonstrate the powders' thermal stability up to 800 °C.

Cell Viability (MTT assay)

The characteristics of cytotoxicity and biocompatibility hold tremendous significance for effective use in biomedical applications [35].The MTT assay, referred to as the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assay, is a commonly employed colorimetric technique for evaluating cell viability and cytotoxic effects [36].The MTT assay is commonly employed to evaluate the toxic effects of polymers, alloys, and ceramics due to its ease of use [37]. MG 63 cells were maintained in DMEM supplemented with 10% FBS, penicillin (100 U/ml), and streptomycin (100 μg/ml) in a humidified atmosphere of 50 μg/ml CO_2 at 37 °C. After being plated in 24-well plates, cells (1 × 105/well) were incubated at 37 °C with 5% CO2. The different sample concentrations were introduced once the cell reached confluence, and it was then incubated for twenty-four hours. Following incubation, the sample was taken out of the well and cleaned using either DMEM without serum or phosphate-buffered saline (pH 7.4). A 0.5% solution of 3-(4, 5-dimethyl-2-thiazolyl)-2,5-diphenyl--tetrazolium bromide (MTT) was added to 100μl/well (5 mg/ml) and incubated for 4 hours. One millilitre of DMSO was applied to each well following incubation. Using DMSO as the blank, the absorbance at 570 nm was determined using a UV spectrophotometer. The MG-63 cell lines were grown in the presence of Hydroxyapatite powders assisted with proline and PVDF for a period of a day, as depicted in Fig. 6. Hydroxyapatite encourages the proliferation of osteoblast-like cells without causing toxicity, it could be considered a valuable material for applications in bone tissue engineering or orthopaedics. For the cytotoxicity evaluation, Hydroxyapatite samples were prepared at concentrations of 1000 μg/ml and 7.8 μg/ml. The cells were treated with these samples for 24 hours, and the assessment of cytotoxicity was conducted using the MTT assay [38]. The results in Table.2indicates the increased cell viability with greater concentrations of hydroxyapatite (HAP) powders assisted with and proline and polyvinylidene fluoride (PVDF) is associated with a larger surface area that promotes cell attachment, increased availability of calcium and phosphate for bone cells, and the material's enhanced capacity to sustain a neutral pH, all of which collectively foster a more conducive environment for cell growth and survival.

P**roliferation study of Sample on *MG 63* cell line**

Cell viability results of HAP nano powders synthesized with 0.2 g Proline and0.2 g PVDF (Fig. 7). The obtained results indicates that hydroxyapatite powders synthesised with proline and PVDF exhibit enhanced bioactivity and have considerable promise for facilitating bone formation.

CONCLUSION

This study offers a promising development in biomaterials for biomedical applications by effectively synthesising hydroxyapatite (HAP) powder assisted by proline and PVDF by hydrothermal method. In synthesising Hydroxyapatite nano powders PVDF acted as the matrix and proline an amino acid greatly acted as growth regulating agents in the formation of HAP. XRD results indicate that the produced hydroxyapatite is devoid of any crystalline impurities. The FT-IR spectra show no signs of impurity peak, confirming the purity of the prepared Hydroxyapatite nano powder. The formation of elongated-spherical HAP particles is confirmed by the SEM and TEM pictures. The powders' exceptional thermal stability has been demonstrated by the TGA curves. The bioactivity and biocompatibility of the prepared nano-HAP powders was confirmed by cell viability tests, which proves cell adhesion and proliferation and free from cytotoxic effects, proving to be capable candidate for orthopaedic applications. Additional research is being conducted to examine the effectiveness of the powders by covering implantable metals with them.

Table 1: The calculated average particle size of HAP powders both with and without additives using Scherer's equation.

Sample code	hkl values	Average crystallite size (nm)
HAP	(002), (102), (210), (211), (222)	34
0.1 g Proline	(002), (210), (211), (212), (222)	13
0.1 g Proline & 0.05g PVDF	(002), (211), (310), (222), (213)	17
0.2 g Proline & 0.2 g PVDF	(002), (211), (202), (222), (213)	12
0. 4 g Proline & 0.1 g PVDF	(002), (211), (310), (222), (213)	21

Table.2: Proliferation study of Sample on MG 63 cell line

Proline and PVDFassisted nano HAP	Concentration (µg/mL)	Cell viability (%)
	1000	66.95
	500	109.97
	250	149.71
	125	192.73
	62.5	222.64
	31.2	265.66
	15.6	308.40
	7.8	351.28
	Cell control	100

ABSTRACT

A major take away from this study is that how customers perceive digital tools significantly influences their engagement and willingness to adopt sustainable dining practices. This means businesses should focus on creating positive customer experiences through well-integrated digital solutions. By utilizing phygital tools, restaurants can not only improve their operational efficiency but also promote sustainability—like cutting down on paper waste with digital receipts, encouraging eco-friendly packaging, and using digital campaigns to inform customers about sustainable practices.

Keywords: Digital Tools, Engagement and Willingness, Digital Solutions, phygital, Digital Campaigns

INTRODUCTION

Marketing has evolved significantly over the decades, adapting to changing consumer behaviours and technological advancements. The advent of digital technology marked a pivotal shift in marketing strategies. The rise of the internet, social media platforms, and mobile devices enabled marketers to engage with consumers in more personalized and interactive ways. This digital transformation allowed for targeted advertising, real-time feedback, and data-driven decision-making, enhancing the efficiency and effectiveness of marketing campaigns (Sam, 2024). Amid this digital revolution, the concept of phygital marketing emerged, blending physical and digital experiences to create seamless customer interactions. Phygital marketing leverages technologies such as augmented reality (AR), virtual reality (VR), and interactive kiosks to bridge the gap between online and offline environments, enhancing customer engagement and satisfaction. Various industries have adopted phygital marketing tools to enhance

customer experiences. In the retail sector, brands have integrated technologies like interactive kiosks and AR to provide personalized shopping experiences, allowing customers to virtually try products before purchasing (Mahoney, 2025). The luxury fashion industry has also embraced phygital strategies, combining traditional craftsmanship with digital innovations to attract new customers and remain competitive. In the restaurant industry, phygital marketing has been utilized to improve customer engagement and operational efficiency. Tools such as QR code menus, mobile ordering apps, and AI-driven chatbots have been implemented to 2 streamline the dining experience, allowing customers to browse menus, place orders, and make payments through their devices (Potharaju, 2024). As more and more consumers prefer personalized, interactive and immersive experiences, phygital tools have gained significant traction in the restaurant industry. While consumers prioritise convenience, they are also concerned with the environmental impact of their choices as there's a growing demand for sustainability (Jacobs & Klosse, 2016). Due to the major shift in consumer preferences and increasing environmental concerns, sustainability is the need of the hour (Weijers et al., 2024). Consumers tend to be eco-conscious while adopting restaurants to dine-in due to the rise in food wastage and carbon emissions (Kim & Hall, 2020). There's also previous studies that show that there is a direct link between sustainable restaurant practices and customer loyalty as such practices by restaurants resonate deeply with values of eco-conscious customers (Kim & Hall, 2020).

Even if we keep the sustainability factor aside, phygital tool's effectiveness can also be studied by looking at another critical metric, ie, customer engagement. Studies show that cognitive, emotional, and behavioural reactions to digital interactions all affect engagement (Bowden, 2009). According to research, customers are more likely to build strong brand-relationship and loyalty if they positively perceive phygital marketing tools (Guzzetti et al., 2024). So it is essential to assess whether there is an impact of customer perception of phygital tools on customer engagement with the restaurant. While there exists sufficient research on phygital marketing strategies in sectors like retail, tourism, healthcare, hospitality, etc, study is limited when it comes to assessing phygital strategies in dine-in restaurant settings. Although significant studies discussed about sustainability in restaurants and customer attitudes towards green initiatives in restaurants (Bschaden et al., 2024)., there are no studies that examine whether phygital marketing tools influence sustainable dining practices. This makes it crucial to address the gap of assessing the perceptions of phygital tools and analyzing whether they have an impact on the adoption of sustainable dining practices and customer engagement. By addressing these objectives, the study will contribute to existing literature on the growth of restaurant industry due to digitalization. It will provide practical implications for restaurant owners who wish to aim for higher customer engagement by adopting sustainable initiatives with the help of phygital marketing tools, which will not only enhance customer retention but also move towards a greener world.

Significance of the Study

The rise of technological advancements in the restaurant industry is opening doors to new and exciting opportunities for restaurant management to better connect with customers. While there exists significant amount of research 4 focusing on phygital tools in different sectors like retail, healthcare and food delivery, there is little to no focus on how these phygital tools are changing the way people perceive dining in. This study strives to explore this gap and analyse how these digital technologies play a role in enhancing customer engagement. With the growing environmental concerns in every aspect, restaurant owners are pressured to take up sustainable initiatives and move towards setting up green restaurant practices. While there are existing studies on green restaurants and brand-relationships, there isn't a study on how customer perception of phygital tools impact sustainable dining practices. Thus, this study becomes significant as it bridges the gap between customer perceptions of phygital tools with both sustainable dining practices and customer engagement. Understanding this angle will help restaurant owners in implementing these phygital tools more effectively and bring in more green initiatives in order to increase customer expectations.

REVIEW OF LITERATURE

Guzzetti, et al. (2024) conducted a study to analyse the psychological responses of consumers with regards to digital technologies adopted in luxurious retail settings. The main aim was to find out whether in-store technologies had a positive or negative view on consumers based on factors like familiarity, belief systems, convenience, etc Batat (2024) examined how consumers perceive duplicating sensory aspects with the help of ERTs and how these aspects enhance their experiences. Conclusions of the study suggest that in metaverse, duplicating sight and touch have positive responses while scent and sound were deemed to be necessary only according to certain contexts.

Bschaden, et al. (2024) tried to investigate whether providing CF labels on the menu drives consumers to be more eco-conscious, leading them to choose sustainable alternatives.s. It was found that simply presenting CF labels had no significant impact on consumer's choice in opting dishes on the menu. Banik (2021) studied how increased engagement with phygital tools in retail stores leads to greater willingness in customers to continue shopping and revisit stores. Data was collected from 237 customers within a span of 16 weeks from shopping malls in China. Structural Equation Modelling was used to analyse data and test their relationships. Kim, et al. (2020) tried to determine the effect of sustainable dining practices on their paper. Structural Equation Modelling and Moderation Analysis was the statistical tests used to find out that ecofriendly restaurant practices does impact customer's hedonic and utilitarian values, with more effect on pleasure-based values.

Soriano, et al. (2024) studied customer choice of ordering touch points and its influence on overall customer satisfaction by focusing on the Philippines restaurant industry to compare the choices of customers between traditional counters and innovative self-order kiosks and whether preference over one has any influence on overall satisfaction of customers. As per the study emotional situations like hurry, nervousness, and convenience impact choices and satisfaction levels. Hu, et al. (2010) tries to examine what are the factors that make customers willing to frequently opt for green restaurants. findings indicate that higher knowledge and awareness of sustainable. practices lead to higher green restaurant patronage. The findings indicate that higher knowledge and awareness of sustainable practices lead to higher green restaurant patronage.

Mele, C., et al. (2023) conducted a systematic review about the phygital transformation, which is the shift of traditional physical experience to a combination of both physical and digital experiences. The paper tries to clearly define the term 'phygital' (physical+digital) which is often described vaguely. Johnson, M., et al. (2021) conducted a study to dive deeper into the psychological and neuroscientific mechanisms that impact consumer buying decisions when exposed to phygital marketing technologies. Findings suggested that usage of phygital technologies has led to a reduction in pain of payment, where customers use digital payment methods and buy now-pay later schemes which reduced their psychological pain compared to using cash as a medium of payment

Weijers, R. J., et al. (2024) aims to investigate how nudging techniques impact customer food choices and how these techniques can promote vegetarian meal choices among consumers of restaurant industry. Three main forms of nudging techniques are used including the hedonic label nudge, chef's recommendation nudge and the salient nudge to influence decision making by customers after going through the menu. Anwar, R. S., et al. (2025) tries to identify the correlation in the adoption of phygital products with innovation, sustainable consumption and customer engagement

Conceptual Development

The existing literature explains that hospitality industry is constantly changing based on the technological advancements, especially phygital marketing, which is the joining of physical and digital elements in order to improve the consumer experience (Hoyer et al., 2020). The following section will discuss reviews about Phygital Marketing , Customer Perception ; Technology Acceptance Model (TAM), Sustainable Dining .

Customer Perception

Customer perception isn't just a cold metric—it's really how we, as individuals, react to new technological innovations. It should be seen as a blend of our personal encounters and the subtle cues that surround these advances; as Zeithaml (1988) noted, our impressions can shape how we behave, sometimes in ways we barely notice. In the realm of phygital marketing, for example, whether we choose to use digital tools while dining is influenced by more than just convenience—it's a mix of gut feeling and broader narratives, as Venkatesh & Davis (2000) have pointed out. Generally speaking, how we gauge a product's value, quality, and the satisfaction it delivers isn't just technical—it's deeply psychological. Zeithaml (1988) reminds us that these subjective judgments really steer our purchasing choices and even our loyalty to a brand. This suggests that these overlapping signals—sometimes redundant, entirely novel—play a crucial role in guiding what we end up believing and buying. Key elements influencing customer perception include brand image & reputation, customer experience, social proof & reviews. Online feedback, reviews, recommendations from friends, and endorsements from influencers significantly impact how potential customers view a brand (Dellarocas, 2003).

Technology Acceptance Model (TAM) :

The Technology Acceptance Model (TAM), introduced by Davis in 1986, aims to explain and predict how users accept new technologies. Its undoubtedly one of the most recognized theoretical frameworks in the fields of information systems and consumer behavior, especially in understanding the reasons behind individuals' adoption of technology-based solutions. TAM suggests that two main factors influence technology adoption: 1. Perceived Usefulness (PU) – This refers to how much a person believes that using a specific technology will improve their performance. Perceived Usefulness (PU) is defined as the extent to which a person believes that a specific technology will enhance their efficiency, effectiveness, and overall performance (Davis, 1989). 2. Perceived Ease of Use (PEOU) – This indicates how much a person feels that using the technology will require little effort. PEOU refers to how easy a user finds a technology to operate and how free it is from complications (Davis, 1989). If a system is seen as challenging to use, users may hesitate to adopt it.

Sustainable Dining

Sustainability in dining refers to the practices that are by nature eco-friendly, thus the dining establishments cause less environmental impact, and at the same time offer high service quality (Grunert et al., 2014). Sustainable dining could be described as having food in such a way that the environmental impact becomes less, ensuring ethically sourced ingredients, reducing waste, and supporting the local economy. It is a concept that fuses together sustainability, public health, and traders' ethics to approach healthy and efficient food supply chains and makes a connection between food production, trade, and consumption. The difficult task is to achieve the goal of striking a 37 sustainable balance between meeting current food needs and conserving resources for also the future (FAO, 2018). Key principles of sustainable dining are Environmentally Responsible Sourcing, Minimizing Food Waste, Ethical and Humane Animal Agriculture, Energy Efficiency in Restaurant Operations, Consumer Awareness and Behavioral Change. With the rise of phygital marketing (physical + digital strategies), restaurants and food brands are leveraging technology to enhance sustainable dining practices

Objectives of the Study

1. To analyse the impact of customer perception on their adoption of sustainable dining practices and engagement with restaurants.
2. To assess customer perceptions about phygital tools in restaurants.

Hypotheses

Hypothesis1

H0: Customer perception of phygital marketing tools does not have a significant positive impact on customer engagement in dine-in restaurants

H1: Customer perception of phygital marketing tools has a significant positive impact on customer engagement in dine-in restaurants.

Hypothesis 2

H0: Customer perception of phygital marketing tools does not have a significant positive impact on the adoption of sustainable dining practices.

H1: Customer perception of phygital marketing tools has a significant positive impact on the adoption of sustainable dining practices.

Hypothesis 3

H0: There is no significant difference in the perception of phygital tools between different demographic factors.

H1: There is significant difference in the perception of phygital tools between different demographic factors.

RESEARCH METHODOLOGY

The study is based on descriptive and analytical techniques and the data were collected using a structured questionnaire. Both primary as well as secondary dta were used for the research. The primary data were collected with the help of structured questionnaire. Secondary Data .The secondary data were collected from various journals, magazines, publications, etc. The study involves a sample of 150 respondents. Purposive sampling is employed by targeting respondents who have interacted with phygital tools.

Data Analysis

The collected data are analysed with the help of software, SPSS-20 and Excel. Before moving on to the detailed analysis, researchers checked the reliability of the dependent variables namely sustainable dining and customer engagements. Skewness and Kurtosis values found within the acceptable range(-1 to +1), indicating that the data follows normality assumption(Table 1). The correlation analysis has been done among these variables to test the relation between the variables. (Table 2). Then to study the influence and impact of perception towards phygital marketing on sustainable dining and customer engagement, 'regression' analysis has been used (given in Table-3). Customer perception is analysed using age and gender.

Regression Analysis

Regression analysis will assess the extent to which perception influences sustainable dining practices and engagement.

Regression Analysis-Impact of Perception on Sustainable Dining

H_0: Customer perception towards phygital tools does not significantly influence sustainable dining practices.

H_1: Customer perception towards phygital tools significantly influences sustainable dining practices.

From the model summary table 3, R = 0.643 indicates a strong positive relationship between perception and sustainable dining practices. R^2 = 0.413 suggests that 41.3% of the variation in sustainable dining practices can be explained by customer perception. Adjusted R^2 = 0.409 confirms that the model is a good fit even after adjusting for the number of predictors. The F-statistic (104.148) is significant at p = 0.000, indicating that the regression model is statistically significant and that perception has a meaningful impact on sustainable dining practices. The standardized beta coefficient (0.643) confirms a strong positive influence. The t-value (10.205) with p = 0.000 further supports that perception significantly affects sustainable dining practices. The constant (intercept) value of 0.987 suggests that even when perception is at zero, sustainable dining practices have a base level. The positive and statistically significant coefficient confirms that as customer perception of phygital tools improves, their likelihood of adopting sustainable dining practices increases. Since the p-value is significant ($p < 0.05$), we reject the null hypothesis (H_0) and accept the alternative hypothesis (H_1). This means that customer perception towards phygital tools has a significant positive impact on their adoption of sustainable dining practices.

Regression Analysis-Impact of Perception on Customer Engagement

H0: Customer perception towards phygital tools does not significantly influence customer engagement with restaurants.

H1: Customer perception towards phygital tools significantly influences customer engagement with restaurants.

The R-value (0.611) indicates a moderate positive correlation between perception and customer engagement. The R^2 (0.374) shows that 37.4% of engagement is explained by perception. The adjusted R^2 (0.370) confirms model reliability. The model is statistically significant ($F = 88.347$, $p = 0.000$), meaning perception significantly impacts customer engagement. The regression equation: Customer Engagement = 1.125 + 0.650 (Perception). A one-unit increase in perception leads to a 0.650 increase in engagement ($p = 0.000$), confirming significance. Since $p < 0.05$, the null hypothesis is rejected, proving perception significantly influences engagement.

Analysis of Perception Towards Phygital Tools

Independent samples t-Test for Gender and Perception

The objective of this test is to determine whether there is a significant difference in the perception of phygital tools in restaurants between male and female customers. The Independent Samples t-test is used as the independent variable (Gender) is categorical, and the dependent variable (Perception) is continuous. The following hypothesis is formulated

H0: There is no significant difference in the perception of phygital tools between males and females.

H1: There is a significant difference in the perception of phygital tools between males and females.

Independent Samples Test for Gender and Perception

The Independent Samples t-test was conducted to examine gender differences in the perception of phygital tools. Levene's Test for Equality of Variances shows a Sig. value of 0.417 (>0.05), indicating equal variances can be assumed. The t-test result ($t = -0.200$, Sig. (2-tailed) = 0.841) shows no significant difference between male and female respondents. Since $p > 0.05$, the null hypothesis (H_0: No significant difference in perception between genders) is not rejected, confirming that gender does not significantly influence perception.

One-Way ANOVA for Age and Perception

Age can influence how individuals perceive and interact with phygital tools in restaurants. Different age groups may have varying levels of familiarity, comfort, and preference for digital technology. To analyze whether there is a significant difference in perception across different age groups, a One-Way ANOVA test is conducted. The following hypothesis is formulated:

H0: There is no significant difference in perception across different age groups.

H1: There is a significant difference in perception across different age groups.

The homogeneity of variance assumption is tested using Levene's Test of Equality of Variance. The test result shows a Levene's statistic of 2.090 and a significance value (p) of 0.085. Since the significance value is greater than 0.05, the null hypothesis of equal variances fails to be rejected at the 5% significance level. This confirms that the assumption of homogeneity of variance is met. Therefore, it is appropriate to proceed with a One-Way ANOVA to compare the mean perception scores across age groups (Table 6.b). The table presents the results of the One-Way ANOVA conducted to examine the differences in perception across various age groups. The ANOVA test results indicate an F-value of 1.669 and a significance value (p) of 0.160. Since the significance value is greater than 0.05, the null hypothesis fails to be rejected at the 5% level of significance. This suggests that there is no statistically significant difference in perception levels across different age groups (Table 6.c).

FINDINGS AND CONCLUSION

The study sheds light on important aspects of customer demographics, dining habits, and how people are embracing digital tools in the restaurant scene. The data also shows that eating out is a common pastime for these individuals, emphasizing the need for a smooth and engaging customer experience. Interestingly, the findings reveal a strong

inclination towards digital adoption, especially with digital menus (83.3%) and digital payments (76%). This indicates a clear trend towards tech-savvy dining experiences. However, the 67% uptake of self-ordering kiosks (44.7%) and in-store digital displays (48.7%) is still somewhat moderate, pointing to a chance for restaurants to raise awareness and offer incentives to boost their usage. Furthermore, digital loyalty programs (28.7%) and AR/VR technology (6.7%) are seeing very little engagement, highlighting the necessity for better promotional strategies and user-friendly designs. A key take away from the study is that customer perception of digital tools plays a significant role in driving both customer engagement and sustainable dining adoption. This means that businesses need to actively shape positive customer experiences through well-integrated digital solutions. By leveraging phygital tools, restaurants can not only enhance operational efficiency but also promote sustainability, such as reducing paper usage through digital receipts, encouraging eco-friendly packaging, and using digital campaigns to educate customers about sustainable practices. In conclusion, the restaurant really needs to sync its strategies with what customers want, making sure that embracing digital tools makes the dining experience better, not more complicated. Striking the right balance between affordability, digital ease, sustainability, and engaging with customers will be crucial for thriving in a restaurant industry that's becoming more tech-focused every day.

ABSTRACT

This study aims to enhance student engagement and learning outcomes in chemistry education through a hands-on, project-based learning approach focused on synthesizing and testing oil-based soaps. Utilizing the saponification process, students created soaps from various oils, including olive, coconut, palm, castor and recycled cooking oils too. This project not only teaches fundamental chemical concepts such as reaction mechanisms and stoichiometry but also incorporates principles of sustainability and environmental science. To carry out this work, included some pedagogical framework like pre-laboratory lectures, detailed experimental procedures, and post-laboratory discussions were used. Students evaluated the synthesized soaps by testing properties such as pH, lathering ability, texture, and antimicrobial effectiveness, cleaning capacity. These evaluations provided practical insights into the chemical properties and real-world applications of the soaps. Survey data and performance assessments indicated a significant increase in student engagement, interest, and comprehension of chemistry concepts compared to traditional lecture-based instructions. Students reported that the hands-on nature of the project, along with its relevance to everyday life and environmental sustainability, made learning more enjoyable and meaningful. This research demonstrates the potential of innovative, experiential learning methods to transform chemistry laboratory education. By integrating practical applications with theoretical knowledge, educators can inspire greater student interest and engagement, leading to improved educational outcomes in the science and engineering.

Keywords: Pedagogical innovation, Soap synthesis, Student engagement, Chemistry education

INTRODUCTION

Chemistry education frequently grapples with the challenge of engaging students and demonstrating the relevance of abstract concepts. Traditional lecture-based methods can often fail to maintain student interest or illustrate the practical applications of chemical principles (Broman and Parchmann, 2014). Project-based learning (PBL) has emerged as a promising pedagogical strategy, offering hands-on, real-world contexts that enhance student involvement and comprehension (Bell, 2010). The hands-on experience of soap making helps students understand the practical applications of chemistry, thereby making learning more engaging and meaningful (Bennett and Lubben, 2006).Chemistry education in India must be thoroughly redesigned to meet the needs and goals of the 21st century. Modern, streamlined syllabi, innovative learner-centric pedagogies, and exams that assess skills, values, and attitudes rather than just knowledge is essential. Achieving this requires regularly empowering chemistry teachers at all levels in all aspects of chemistry education, including the strategic use of technology (Bakhshi *et al*., 2020). Integrating sustainability topics into the curriculum has been shown to enhance student awareness and interest (Burmeister and Eilks, 2013). Soap synthesis projects, which utilize both plant-based and recycled oils, provide a practical framework for discussing sustainable practices (Hansen *et al*., 2014). Researchers highlighted the importance of integrating chemistry education with real-world contexts to enhance student learning and engagement. Students demonstrated higher-order thinking and fluid transitions between scientific concepts and practical applications when engaging in context-based tasks. These findings underscore the potential for context-based chemistry education to foster deeper understanding and meaningful learning experiences for students. (King and Ritchie, 2013). Students now prioritize collaborative, peer, and self-directed learning, with many medical schools in Asia incorporating Problem-Based Learning (PBL) into their curricula.

Despite some challenges for teachers and administrators, PBL is widely accepted by students globally and is seen as a promising tool for all fields, particularly in Medical and Dental education (Jaganathan, S., 2024). Problem-based learning (PBL) effectively enhances essential industry skills, both hard and soft, making it a valuable educational approach. However, its successful integration into content-heavy undergraduate programs in South Asia necessitates a systematic redesign, as evidenced by effective course proposals and collaborative workshops with institutions from Nepal and Bhutan. (Acharya, S. *et al*., 2021). In summary, problem-based learning (PBL) is an effective pedagogical approach that fosters critical thinking, problem-solving, and self-directed learning among students. Despite the traditional content-heavy and instruction-based curricula in South Asian undergraduate programs, redesigning these courses to incorporate PBL methodologies shows promise. Utilizing Design Thinking workshops to guide the course redesign process has allowed for the development of feasible and innovative solutions that are currently being implemented and evaluated in various institutions (Bhaumik R., 2019). Engaging students in relevant and hands-on experiments can foster deeper interest in the subject matter and improve educational outcomes (Blumenfeld *et al*., 1991). Furthermore, interdisciplinary approaches linking chemistry with fields such as biology and environmental science can enhance students' holistic understanding of scientific principles (Holbrook and Rannikmae, 2009). The literature survey reveals the considerable potential of integrating advanced pedagogical methodologies such as problem-based learning (PBL) in both educational and industrial settings.

These methods enhance critical thinking, problem-solving, and self-directed learning among students, preparing them for real-world challenges. Despite the promising outcomes, significant challenges remain, particularly in content-heavy curricula that require systematic redesigns to accommodate these innovative approaches. Strong partnerships between academia, industry, and international bodies are essential to successfully navigate these challenges and implement effective solutions. Addressing these issues will align educational institutions with global standards, ultimately enhancing their competitiveness and the quality of graduates (Krishnan, M. S., and others 2016). The literature survey in chemistry education underscores the need for integrating sustainable development principles into the curriculum to foster scientific literacy. Incorporating socio-scientific issues and interdisciplinary approaches enhances the relevance and application of chemistry in addressing real-world challenges. These strategies not only improve educational outcomes but also prepare students for active roles in society by

emphasizing critical thinking and problem-solving skills (Eilks, I., *et. al.*, (2017). This study explores the impact of a soap synthesis project on student engagement and learning outcomes in high school and undergraduate chemistry courses. By blending theoretical knowledge with practical applications, this pedagogical approach aims to inspire greater student interest and engagement, leading to improved educational results in the sciences.

MATERIALS AND METHODS

Population for the current study

For the present study population was the 4th semester's students of Batchlor of Chemical Engineering of Government Engineering College, Valsad. They were given orientation and explanation during the laboratory class about the soap making experiments to be performed by self. Students were given some procedures of soap making and testing to study the best one from the different available in literatures and books from the library. They were divided in groups of three or six students of each, total 154 students in 35 groups were participated in this study. They were given the choices to select the oil for soap making ang ask to bring. Students were instructed to collect materials including chemicals, different oil samples of their own choices instruments and required glass wares, papers and other testing kits from the store.

Materials

For the present work students were in the leading role along with the guide faculty, materials required and shown in the Table 1 and 2 were used in the soap preparation and testing experiments:

Experimentals

As per the prior instructions students were performed pre-decided tasks with procedural steps to carry out the experiment in presence of faculty during their respective laboratory time slots. (Table-3, 4)

Data Collection and Analysis

Data from each test were recorded in tables and analysed to compare the properties of soaps prepared by different groups of students from different oils.(Table-5)

RESULTS AND DISCUSSION

The synthesis and testing of soaps from various oils were evaluated based on student feedback, pH testing, lathering ability, texture, antimicrobial testing, and cleaning capacity. The data, as summarized in the table, reveals significant variations in the properties and student preferences for the different oil-based soaps. The student feedback was categorized on a scale of A, B, and C (as per table-4). The grading indicates varying levels of satisfaction with the soaps prepared from different oils (Fig-1 to5). Coconut oil soap was highly rated by students, with a majority rating it as (B) and a few considering it the (C). This aligns with its excellent lathering ability and antimicrobial properties. Castor oil soap had a good reception, with feedback leaning towards(B) and a few students considering it (C), likely due to its moisturizing properties and lathering ability. Sesame oil soap had mixed feedback, with a significant number rating it as (C). This could be due to its gentle texture and balanced lathering ability. Sunflower oil soap received mostly positive feedback, with ratings spread across (B) and (C), possibly due to its good lathering and cleaning capacity. Rice bran oil soap had favourable feedback, mostly rated as (B), likely because of its smooth texture and good cleaning properties. Rice bran oil soap had favourable feedback, mostly rated as (B), likely because of its smooth texture and good cleaning properties (Fig-1 to5). Mustard oil soap received moderate feedback, mainly rated as (B), due to its distinct cleaning capacity. Groundnut oil soap was highly rated, with most students giving it a (B) rating, reflecting its good lathering and antimicrobial properties. Soybean oil soap had mixed feedback, with moderate ratings across (B) and (C), likely due to its gentle texture and moderate antimicrobial activity. Waste cooking oil soap had the least favourable feedback, indicating variability in quality and performance(Fig-1 to5). The pH values of the soaps ranged within acceptable limits for skin safety. All soaps maintained a pH within the range of

8-10, suitable for skin use, with slight variations. Texture was a significant factor in student preferences, affecting the overall usability of the soaps. The antimicrobial effectiveness varied, influencing student perceptions of cleaning efficacy. Cleaning capacity, as perceived by students, showed variability among the soaps. The results indicate that the type of oil used in soap synthesis significantly affects the soap's properties and student preferences. Coconut oil soap emerged as a standout in terms of lathering, antimicrobial activity, and overall student satisfaction. Its rapid trace time and firm texture make it a favourite among students, aligning with previous studies that highlight the benefits of lauric acid in soap making (Fig-1 to5, Table-5). Recycled cooking oil soap, while demonstrating the feasibility of using waste materials, showed mixed results in terms of texture and antimicrobial activity. This highlights the importance of consistency in raw materials for achieving desired soap properties (Table-5). The hands-on project significantly enhanced student engagement, with many expressing increased interest and motivation in chemistry. The practical application of theoretical concepts through soap synthesis provided a meaningful learning experience, emphasizing the value of project-based learning in science education. Student engagement and learning outcomes were assessed through surveys and performance evaluations before and after the experiment. This detailed procedure ensures reproducibility and provides students with a comprehensive understanding of both the theoretical and practical aspects of soap making and testing.

CONCLUSION

The study demonstrated a significant increase in student engagement and motivation
Active Learning: By participating in the soap-making process, students were able to see the real-world application of chemical principles, which enhanced their interest and understanding.
Ownership of Learning: Students took ownership of their learning by preparing and testing their own soaps. This ownership led to a deeper investment in the learning process and a greater sense of accomplishment.

Students developed critical thinking and problem-solving skills
Experimental Design: Students were involved in designing experiments, which required them to think critically about variables, controls, and outcomes.
Data Analysis: Analyzing the results of their experiments helped students develop skills in data interpretation and scientific reasoning.

The project fostered collaboration and communication skills
Teamwork: Students worked in groups, which helped them learn to collaborate, share ideas, and solve problems collectively.

Communication: Presenting their findings required students to articulate their results and the scientific principles behind them clearly and effectively.
The pedagogical aspects of this study, focused on project-based learning through the synthesis and testing of oil-based soaps, offer a robust framework for enhancing student engagement, interdisciplinary learning, and critical thinking. This method effectively improves current educational practices and holds significant potential for future researchers. By developing and implementing innovative, hands-on learning experiences, researchers can foster a deeper understanding of scientific principles and their real-world applications. Building on this model, future researchers can advance science education, making it more interactive, relevant, and impactful for students.

ACKNOWLEDGEMENT

The author extends heartfelt thanks to the Head of the Department of Chemical Engineering and the Principal of Government Engineering College, Valsad, for their inspiration and guidance. Appreciation is also given to all colleagues, subject teachers, store officer, non-teaching staff, and students of the department for their support and active participation.

Table 1: Type of oils selected by students ang groups

Sr. No.	Selected Oil	Total number of Students	No. of Student Groups
1	Coconut Oil	19	4
2	Palm Oil	12	3
3	Castor Oil	14	3
4	Sesame Oil	9	2
5	Sunflower Oil	14	3
6	Rice Bran Oil	13	3
7	Neem Oil	9	2
8	Cotton seed Oil	15	3
9	Mustard Oil	13	3

10	Ground Nut Oil	19	5
11	Soybean Oil	9	2
12	Waste cooking Oil	8	2
Total	154	35	

Table 2: Materials used for soap making

Item	Particulars
Oil	Coconut Oil, Palm Oil, Castor Oil, Olive Oil, Sesame Oil, Sunflower Oil, Rice Bran Oil, Neem Oil, Almond Oil, Mustard Oil, waste cooking oil
Chemicals	Sodium hydroxide (NaOH), Distilled water
Equipment	Digital scale, Safety goggles and gloves, Heat-resistant glass beakers, Stainless steel mixing spoons, Thermometer, Soap moulds, pH strips, Hardness testing kit, antimicrobial testing materials

Table 3: Task and steps for soap making

Task	Steps
Preparation	• Safety goggles and gloves were worn throughout the experiment. • All equipment was cleaned and dried to ensure no contamination
Lye Solution Preparation	• Sodium hydroxide (NaOH) was carefully weighed according to the required amount for each type of oil used. • NaOH was slowly added to a measured amount of distilled water while stirring continuously. This solution was allowed to cool to a temperature between 40-45°C.
Oil Preparation	• Each type of oil (olive, coconut, palm, and recycled cooking oil) was measured and poured into separate heat-resistant glass beakers. • The oils were heated to a temperature between 40-45°C.
Mixing	• The cooled lye solution was slowly poured into the heated oils while stirring constantly. • The mixture was stirred until trace was achieved, indicating the saponification process had begun. This was observed when the mixture thickened and left a visible trace when drizzled on its surface.
Moulding	• The soap mixture was poured into moulds and covered to maintain warmth. • The moulds were left undisturbed for 24-48 hours to allow the soap to harden
Curing	• After removing the soap from the moulds, it was placed in a well-ventilated area to cure for 4-6 weeks. This curing process allowed excess water to evaporate, resulting in a harder bar of soap.

Table 4: Soap Testing and processes used

Test	Process	Possible Result Scales
pH Testing	• Small samples of each type of soap were dissolved in distilled water. • pH strips were used to measure the pH of the soap solutions to ensure they were skin-friendly (ideally between 8-10)	A: Less Than Ideal B: Ideal C: More than Ideal
Lathering Ability	• 1 g of each soap was dissolved in 100 ml of water in 250 ml measuring cylinder. • Shaken well for 1 minute and foam height was measured. Each type of soap was tested for lathering ability by rubbing it between wet hands and observing the amount and stability of the lather produced.	A: Good B: Very good C: Excellent
Texture	• Textures of soaps were observed in three categories by students viz. Soft, Hard and Very hard	A: Soft B: Hard C: Very Hard
Antimicrobial	• Antimicrobial effectiveness was evaluated by inoculating agar plates	A: Poor

Testing	with bacterial cultures (e.g., E. coli). • Small soap samples were placed on the agar plates, which were then incubated for 24-48 hours. • Zones of inhibition around the soap samples were measured to assess antimicrobial activity.	B: Good C: Very good
Cleaning Capacity	• Each sample soap (0.5 g) solution was prepared in a test tube with 20 ml of distilled water. • A drop of oil was placed on filter paper. • The filter papers with the oil spot were immersed in a test tube containing soap solution. • Each test tube was shaken vigorously for 1 minute • The filter papers were removed and rinsed with distilled water and the degree of cleanliness in eachfilter paper was observed.	A: Good B: Very good C: Excellent

Table 5: Experimental result data

Oil type	**Student feedbacks for soaps prepared by themselves, No. of students gave grading on the scale A, B and C (as per Table-4)**

ABSTRACT

To evaluate the quality of medications for therapeutic value and effectiveness determined by the concentration of their active ingredient, standardization of herbal formulation is crucial. In 1999, the World Health Organization (WHO) provided a comprehensive process for standardizing herbal medications with a single ingredient. However, the consistency and composition of these medications differ from maker to manufacturer, which impacts the formulation's therapeutic efficacy. Therefore, a system for the assessment of herbal medications must be developed. The study's goals were to perform HPTLC to identify phytochemicals in "*Marichadi gutika*" and physiochemically analyze the formulation of "*Marichadi gutika*" according to the Ayurvedic Pharmacopoeia of India (API) standards. This study aims to assess the primary drug standardization factors, such as organoleptic, physico-chemical, phyto-chemical analysis, and HPTLC study, which will help in recognizing the authentication of the formulation. Various phytoconstituents present in different parts of the plant are identified with the help of phytochemical screening, and through HPTLC electronic image of the chromatographic fingerprint of the identified phytochemical constituents is obtained. The physicochemical evaluation of *Marichadi gutika* was found to be in the acceptable range as per Ayurvedic Pharmacopoeia of India (API), which confirms its authenticity and quality. The HPTLC analysis of *Marichadi gutika* revealed the presence of various phytochemicals that are Bronchodilator, Anti-tussive, Mucolytic, Expectorant, Anti-inflammatory, antioxidant, and Anti-microbial. The study results obtained confirmed standards for medicine

manufacturing and the efficacy of *gutika* and can be serve as benchmarks for quality assurance and quality control in this traditional medicine.

Keywords: *Marichadi gutika,* Phytochemical, Physicochemical, Bronchodilator, ASTHMA, COPD, HPTLC

INTRODUCTION

The primary goal of researching chemical analysis in pharmaceutical preparations is to determine the purity and activity of natural or manufactured biologically active chemicals[1]. Analysis of current Ayurvedic research always calls for quick, dependable, and highly effective techniques. The dependability of these methods declines due to low sensitivity and efficiency as well as broad interactions in the studies used in our routine clinical uses. Therefore, for *Ayurveda* to be accepted globally, safety studies of diverse herbal-mineral formulations are also required[2]. Both planar methods and high-performance liquid and gas chromatography are used to systematically evaluate the qualitative and quantitative components of a molecule. Chromatographic techniques have gained popularity recently, both in regular analysis and in research institutions[3]. The topic of standardizing herbal drugs is extremely broad and complex. Regarding herbal remedies and their connection to human physiology and brain function, there is a great deal to learn and a plethora of seemingly incompatible beliefs. The acceptability and safety of the medication are significantly influenced by the preparation and quality of the raw materials[4]. Thin-layer chromatography (TLC) is the foundation of high-performance thin-layer chromatography (HPTLC), which has been enhanced to allow for quantitative chemical analysis and to increase the resolution of the substances that need to be separated. Both the identification and detection of impurities, as well as the identification and quantification of active substances, are done using HPTLC [5]. The Department of AYUSH in India has initiated a central effort to develop standardized processes for the manufacturing method of developing the pharmacopeia guidelines for Ayurvedic medications. *Marichadi Gutika*, a popular *Ayurvedic* composition made from a variety of herb mixes, is well-known. for people of all ages, this is recognized to address respiratory issues such as chronic bronchitis, asthma, COPD, and Tuberculosis. An effective *Ayurvedic* medication, *Marichadi Gutika,* can help the body's *Vata* and *Kapha Doshas* remain balanced, which is crucial for the *Samprapti* of *Pranavaha srotas.* The chemical components of *Marichadi gutika*, which are known to have Bronchodilator, Anti-tussive, Mucolytic, Expectorant Anti-inflammatory, and Antioxidant properties, may aid in providing sufficient relief by lowering Dyspnea. It decreases nasal inflammation, eases congestion, clears mucus, eases sneezing, calms throat irritation, aids in asthma control, and strengthens immunity against allergies[6]. In this study, *Marichadi Gutika* was made in a GMP-certified Ayurvedic pharmacy in accordance with normal operating standards. It underwent analytical techniques such as an organoleptic evaluation (Color, Odor, taste, and appearance), physicochemical analysis (hardness, friability, disintegration time, loss on drying, total ash, acid-insoluble ash, water-soluble extract, alcohol-soluble extract, and pH) as per the norms of Ayurvedic Pharmacopoeia of India (API)[7]. and Indian pharmacopeia (IP)[8]. The study also focused on identifying the phytochemicals in *Marichadi gutika* using HPTLC and evaluating the therapeutic potential of *Marichadi gutika.*

AIMS AND OBJECTIVES

To evaluate the organoleptic characters of the *Marichadi gutika*.
To assess the physiochemical, phytochemical, and HPTLC parameters of *Marichadi gutika.*

MATERIALS AND METHODS

Collection of plant material
All of the raw drugs were bought from Vadodara's verified suppliers.

Identification and authentication of Raw Drugs

Identification and authentication of raw drugs was done by the Department of Dravya Guna, Parul Institute of Ayurveda, Parul University, Vadodara, Gujarat.

Method of preparation of *Marichadi gutika.*

मरिचं कर्षमात्रं स्यात्पिप्पली कर्षसम्मिता ।
अर्धकर्षो यवक्षारः कर्षयुग्मं च दाडिमम् ।।
एतच्चूर्णीकृतं युञ्जादष्टकर्षगुडेन हि ।
शाणप्रमाणां गुटिकां कृत्वा वक्त्रेण धारयेत्।।
अस्याः प्रभावात्सर्वेऽपि कासा यान्त्येव संक्षयम् । (Sa. Sa. Ma. Kha 7/13-15) [9]

Ingredients and Pharmacological activity of *Marichadi gutika* (Table No 1)

Maricha 1 part, *Pippali* 1 part, *Yavakshara* 1/2 part, and *Dadima* 2 parts Grounded in the form of Powder. All the Powder will be mixed with 8 parts of *Guda* and triturated properly until we get a homogeneous mixture. The paste will be converted into a table of 500 mg by a table-punching machine. And dried in shades and stored in an airtight container.

Methods of evaluation of *Marichadi gutika.*

Methods of evaluation of *Marichadi gutika* were analysed utilizing all standard qualitative and quantitative parameters in the laboratory of G.M.P accredited Parul Ayurveda Pharmacy, Vadodara, Gujrat.

Chromatograph profiling by HPTLC [15] **-** the process. TLC. While High-performance thin-layer chromatography uses the latest technology, chromatographic stationary phases provide the optimum separation efficiency at each stage of of TLC. It uses the same principles as High-Performance Thin Layer Chromatography (HPTLC) is an advanced version

Preparation of Test Solution: Test solution preparation involves weighing 5 grams of the sample in a beaker and adding 100 ml of methanol. To get clean extracts, sonicate them for 16 hours and filter them using plain filter paper. The HPTLC plate was coated with a filtered solution of the formulation extract and standard.

Procedure for HPTLC: On a TLC plate consisting of Aluminium sheets coated with Silica Gel 60 F_{254} of thickness 8 mm, 5 µL, 10 µL, and 15 µL of the samples were deposited by the LINOMAT 5 applicator. Plates were then developed for 20 minutes in a twin trough chamber that had been previously saturated with the mobile phase, which consisted of Toluene, Ethyl acetate, Methanol, and Formic acid (7:5:1:0.5v/v/v/v). The plates were allowed to develop for 80 mm and left to air dry for five minutes on a TLC Plate heater set to 100± 5^0CWith the aid of CAMAG Vision CATS software, the developed plates were observed in a visualizing chamber and scanned on a CAMAG TLC scanner at 254 and 366 nm. The chromatograms, number of peaks, and their Rf values were determined at wavelengths of 254 and 366 nm.

RESULTS AND DISCUSSION

Organoleptic evaluation

Organoleptic properties, which are evaluated by Color, Odor, Taste, Texture, and other aspects, are one of the most important criteria for selecting raw ingredients and ensuring the quality of the final product. Organoleptic characteristics of *Marichadi gutika* (Table No 3)

Evaluation of physicochemical parameters

Loss on Drying

It is used to ascertain the sample's moisture content or its water and volatile constituents. A dry and tared flat weighing vial containing 5g of the medication was precisely weighed before being baked for 5 hours at 110C. The percentage was computed using the starting weight as a guide.

In this sample of *Marichadi gutika,* the loss of drying was 5.49 %, i.e, the sample has a long shelf life and will not deteriorate if stored correctly.

Determination of pH value

To utilize a pH meter to measure the sample's pH, a 10% w/V aqueous solution was made.

The pH value of *Marichadi gutika* was 6.

Total ash value

The amount of total inorganic compound can be measured using the total ash value method. For example, physiological ash, which comes from plants, and nonphysiologically ash, which comes from foreign materials that stick to the drug's surface, particularly sand and soil, etc. A precisely burned and tarred silica dish was used to hold 2g of medicines. The thermal treatment was performed by gradual heating to 600^0allowed to stand for thirty minutes, and weighed. C until turning white in a muffle furnace after evenly distributing the material. The crucible was cooled, The Total ash value of *Marichadi gutika* was 8.56 %.

Acid insoluble ash

insoluble in acid was calculated. weight became neutral or constant. For the air-dried preparation, the substance heated for five minutes. This insoluble material was recovered on ashless filter paper and washed with hot water until its We can only determine the availability of Silica through the acid-insoluble ash test. The ash was then treated with 25 ml of diluted hydrochloric acid and The acid-insoluble ash of *Marichadi gutika* was 4.34%.

Water soluble extractive value

The water-soluble extractive values indicated the presence of inorganic compounds, acids, and sugars. A closed flask containing 5g of coarsely powdered, air-dried herbal material was soaked in 100ml of chloroform water for 24 hours, shaken continuously for 6 hours, and then allowed to rest for another 18 hours. To prevent losing the solvent, it was filtered right away. Next, 25 ml of the filtrate was dried in a shallow dish with a tared bottom at 105°C until it reached a consistent weight. The percentage of water-soluble extractives is calculated using the air-dried herbal material as a reference and expressed as a percentage. The water-soluble extractive value of *Marichadi gutika* was 41.8 %.

Alcohol soluble extractive value

The alcohol-soluble extractive values suggest there are polar components present in the plant sample, including phenols, alkaloids, steroids, glycosides, flavonoids, and various secondary metabolites. We took 5g of the coarsely powdered, air-dried remedy and soaked it in 100 ml of alcohol in a sealed flask for 24 hours, giving it a shake every 6 hours, then let it sit for an additional 18 hours. To prevent any loss of the solvent, we quickly filtered 25 ml of the liquid and dried it in a shallow dish at 105°C until it reached a consistent weight. Finally, we calculated the percentage of alcohol-soluble extractives based on the air-dried remedy and expressed it as a percentage. The alcohol-soluble extractive value of *Marichadi gutika* was 19.1 %. Physio-Chemical Parameters of *Marichadi gutikac* (Table No 4). The HPTLC Chromatograph of *Marichadi gutika* developed at a wavelength of 254nm with volumes of 5.0 µL, 10.0 µL, and 15.0 µL is depicted in Figures 1, 2, and 3, respectively. The Chromatograph of *Marichadi gutika* developed at a wavelength of 366nm with volumes of 5.0 µL, 10.0 µL, and 15.0 µL is depicted in Figures 4, 5, and 6, respectively, showing the Rf Values, Chromatograph fingerprint, peak height, and percentage area. By comparing the results (Fig 1-6) at the Phytochemical fingerprint and chemometrics online database [16] and IMPPAT 2.0[17], chemical substances were then identified as mentioned in Table 5-6 along with their Bioactivity.

DISCUSSION

In Ayurvedic medicine, physicochemical testing and HPTLC (High-Performance Thin-Layer Chromatography) are essential because they guarantee quality control by verifying the potency, validity, and purity of herbal ingredients. They also help identify adulteration by identifying contamination or the replacement of inferior or dangerous components. Monitoring for dangerous heavy metals, pesticides, and microbiological contamination can also be accomplished with the help of physicochemical assays. By guaranteeing therapeutic efficacy with reliable, high-quality materials, such studies improve patient care by improving treatment outcomes and reducing side effects by removing the possibility of contamination and adulteration. Additionally, offering reliable data to support the creation of evidence-based medications advances Ayurvedic research. Here, the chromatogram scanned at 254 nm and 366 nm shows a variety of peaks and their obtained Rf Values (Figures 1-6). The high-performance liquid chromatography (HPTLC) of the methanolic extract of *Marichadi gutika* showed the presence of multiple phytoconstituents in various concentrations. We obtained higher peaks based on the Rf value at 254 nm with a 15.0 µL volume and the Rf value at 366 nm with a 15.0 µL volume as illustrated in Table 5-6). The Rf Value, Relative Rf, and peak area % were then compared to standard references to estimate the compound name. According to high-performance thin-layer chromatography, the phytochemicals extracted from *Marichadi gutika* have Anti-asthmatic, Anti-allergic, Bronchodilator, Anti-tussive, Mucolytic, Expectorant, Anti-inflammatory, and Antioxidant properties. (Table 6,7). The chromatogram also reveals compounds that act as antibacterial, Anti-fungal, Antiseptic, Antiviral, Anti-parasitic, Antitumor, and anticarcinogenic activity (Table 6, 7). The HPTLC chromatogram also displays many chemicals that demonstrate the following actions: anti-obesogenic, anti-plaque, and vasodilator, all of which can act as cardioprotective and hepatoprotective agents. Also has anxiolytic, antidepressant, and antispasmodic properties. Immunomodulatory activity, bioavailability enhancement, pro-oxidant, and protein precipitation change the way the body's immune system functions, help to regulate the immune system and decrease inflammatory replication. In light of the discussion that followed, we can conclude that the primary derivatives or metabolites of phytochemical elements detected by HPTLC analysis of Marichadi gutika could be useful in addressing respiratory issues such as chronic bronchitis, asthma, and COPD.

Limitations and Future Scope of the Study

The phytochemicals found in *Marichadi gutika* using HPTLC with Rf Value are only primary derivatives of phytochemical components, which limits the knowledge of the drug's pharmacological effect and therapeutic potential. Analytical methods like GCMS (gas chromatography-mass spectrometry) and LCMS (liquid chromatography-mass spectrometry) can be used to determine bioactive phytochemical components in *Marichadi gutika*.

CONCLUSION

Prior to being utilized medicinally, any formulation must undergo a thorough investigation. The quality of the ingredients employed in the manufacturing of the medication determines its therapeutic efficacy. The preparation and quality of Vajra Guggulu are examined in this study utilizing high-performance liquid chromatography (HPTLC) and physicochemical evaluation as specified in the Ayurvedic Pharmacopoeia of India (API). The study will aid in *Marichadi Gitika's* authentication because previous investigations, such as those on pharmacopeia, are not mentioned in the conventional literature. The current study's findings can be used as a reference monograph for drug formulation creation, quality analysis, and evaluation of the therapeutic potential of *Marichadi gutika* using GC-MS pharmaceutical analysis and additional pre-clinical research.

Table No 1: Ingredients and Pharmacological activity of *Marichadi gutika*

SR NO	DRUGS	BOTANICAL NAME	PROPORTION	PART USE	PHARMACOLOGICAL ACTIVITY
1	*Marica*	*Piper nigrum*	1 part	Seed	Anti-asthmatic, Bronchodilators, mucolytic, expectorant, Digestivestimulant, Carminative[10].
2	*Pippali*	*Piper longum*	1 part	Fruit	Anti-asthmatic, Bronchodilator, expectorant, Mucolutic, Antibiotic, Analgesic, Digestive stimulant[11].
3.	*Yavakshara*	*Hordeum vulgare*	1/2 part	-	Expectorant, mucolytic Digestive stimulant, Carminative[12].
4	*Dadima*	*Punica granatum*	2 parts	Seed	Anti-histamine, anti-tussive (cough suppressant),Anti-bacterial, digestive stimulant[13].
5	*Guda*	*Saccharum officinalis*	8 parts	-	Mucolytic, Cough suppressant, Anti-inflammation, Anti-bacterial, Digestive stimulant [14]

Table 2: Chromatographic conditions for HPTLC of *Marichadi gutika*

Application Mode	CAMAG Linomat 5 (S/N:280008) Applicator
Filtering System	Simple filter
Stationary Phase	MERCK - HPTLC Silica gel 60 F254 on Aliminium sheets
Application (Y axis) Start Position	8.0 mm
Development End Position	80 mm from the plate base
Sample Application Volume	5µL, 10µL, 15µL
Distance Between Tracks	13.4 mm
Development Mode	CAMAG TLC Twin Trough Chamber
Chamber Saturation Time	20 minutes
Mobile Phase (MP)	Toluene: Ethyl acetate: Methanol: Formic Acid (7:5:1:0.5v/v/v/v)
Visualization	@ 254 nm and @366 nm
Drying Mode, Temp. and Time	TLC Plate Heater Preheated at 100±5^{0}C for 5 minutes

Table No 3: Organoleptic characteristics of*Marichadi gutika*

SR NO.	CHARACTERS	OBSERVATION
1	Color	Dark brown
2	Odor	Astringent
3	Taste	Spicy sweet
4	Consistency	Solid (tablet form)

Table No 4: Physio-Chemical Parameters of *Marichadi gutika*

Sr. No	Parameter	Result	Normal limit [7-8]
1.	Loss of drying at 110 ° C (%w/w)	5.49	≤ 15%
2.	pH Value (10% Aqs)	6	5.5-7.5
3.	Total Ash Value (%w/w)	8.56	≤ 10%
4.	Acid Insoluble Ash Value(%w/w)	4.34	(Variable)
5.	Tablet Hardness (Kg/cm2)	5.50	4-12 kg/cm²
6.	Tablet Disintegration Time (mins)	20	(Variable)
7.	Alcohol soluble extract (%w/w)	19.1	20-40%
8.	Water soluble extract (%w/w)	41.8	15-30%
9.	Tablet Average weight (Mg) % of lowest weight % of highest weight	501 1.4 3	-
10.	Tablet Friability (%)	0	≤ 2%

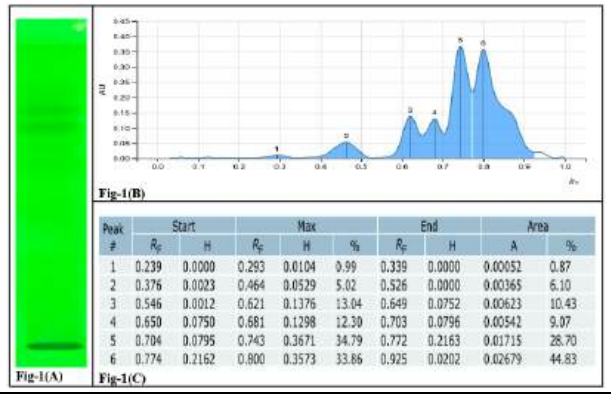

Table No 5: Phytochemical name and their Bioactivity based on Rf Value@254 nm and 15.0 µL volume

Peak no	Rf value	% area	Phytochemical name	Bioactivity
1.	0.042	0.22	Glycoside	Anti-inflammatory, Antioxidant, Antibacterial, Anti-microbial, Antiseptic,Anti-cancer, Immunomodulatory Activity, Neuroprotective, Analgesic, Purgative, laxative, Antipyretic,Antispasmodic [18]
2.	0.464	7.23	Terpene carvone	Anti-allergic,Anti-Inflammatory, Antioxidant, Antimicrobial, Anticancer, Anti-hypertensive, Anti-plaque, wound healing, Anti-ulcer [19]
3.	0.619	12.37	Isoquercittrin	Anti-Inflammatory, Antioxidant [20], Anti-allergic, Anti-diabetic, Anti-hypertensive, Chemoprotective effect against oxidativestress, Antiproliferative, cardioprotective [21]
4.	0.679	11.09	Piperine	Bronchodilator, Anti-Asthmatic, Anti-Tussive, Mucolytic, Expectorant, Anti-Inflammatory, Antioxidant, Anti-ulcer, Anti-Carcinogenic, Hepatoprotective, Anti-Depressant, Immunomodulatory, Bioavailability Enhancement, Digestive stimulator, Carminative [22]
5.	0.746	25.71	Alkaloid	Bronchodilators, Anti-Asthmatic, Antitussive, Nasal Decongestants, Vasodilators, Anti-Inflammatory, Anti-Plaque, Anti-hypertensive, vasodilator, Cardioprotective Agents [23]

ABSTRACT

The gut microbiota generates a wide spectrum of bioactive metabolites that function as key regulators of host physiology and disease progression. These metabolites, including short-chain fatty acids, bile acid derivatives, indole compounds, and polyamines, exert diverse pharmacological effects by modulating immune responses, neurotransmission, metabolism, and epigenetic pathways. Growing evidence highlights their potential as natural scaffolds for drug discovery and as modulators of existing therapeutic agents, thereby opening new avenues for drug repurposing. Notable examples include butyrate analogs with anticancer activity, bile acid derivatives influencing metabolic disorders, and microbiota-mediated modulation of metformin and immunotherapies. Despite promising prospects, challenges such as individual microbiota variability and the complexity of host–microbe interactions remain significant. Advances in metabolomics, network pharmacology, and computational modeling may overcome these limitations. Overall, microbiota-derived metabolites represent a novel frontier in pharmacology, offering unique opportunities for innovative drug discovery and precision therapeutics.

Keywords: gut microbiota, microbial metabolites, drug discovery, drug repurposing, pharmacology, short-chain fatty acids, metabolic regulation, neuroimmune signaling, bile acid derivatives, precision medicine

INTRODUCTION

The human gut harbors a dense microbial ecosystem, often referred to as the "hidden metabolic organ," comprising over 100 trillion microorganisms with diverse biosynthetic capacities [1]. Beyond their role in digestion, these microbes generate a wide variety of metabolites that interact with host tissues and influence health and disease states. Such microbiota-derived metabolites, including short-chain fatty acids (SCFAs), bile acid derivatives, indole compounds, and polyamines, act as signaling molecules that can modulate immune function, neuronal communication, metabolic regulation, and even drug responses [2,3]. Over the past decade, these metabolites have attracted increasing pharmacological interest due to their potential as drug scaffolds and therapeutic modulators**.** For instance, SCFAs such as butyrate exhibit anti-inflammatory and epigenetic effects, positioning them as promising leads in cancer and inflammatory disease therapy [4]. Similarly, indole derivatives produced from tryptophan metabolism regulate gut barrier integrity and neuroimmune signaling, linking microbial metabolism to neurological and psychiatric disorders [5]. Importantly, microbial metabolism also influences the pharmacokinetics and pharmacodynamics of many clinically used drugs, including metformin, digoxin, and immune checkpoint inhibitors, thereby opening opportunities for drug repurposing [6,7].

Despite these advances, the field faces significant challenges. Variability in gut microbiota composition across individuals complicates the translation of findings into standardized therapies. Moreover, the complexity of host–microbe–drug interactions requires integration of metabolomics, computational pharmacology, and systems biology to unravel mechanistic insights [8]. Addressing these challenges could accelerate the incorporation of microbiota-derived metabolites into mainstream pharmacology, enabling precision medicine approaches tailored to the individual microbiome profile. Therefore, this review aims to comprehensively examine the pharmacological potential of gut microbiota-derived metabolites**,** with a focus on their role in drug discovery and repurposing**.** By highlighting both established evidence and emerging perspectives, we seek to underscore their transformative potential as a new frontier in modern pharmacology.

MATERIALS AND METHODS

Types of Microbiota-Derived Metabolites

The gut microbiota synthesizes an extensive range of metabolites that mediate host–microbe interactions and exert significant pharmacological effects. These metabolites arise from the fermentation of dietary substrates, modification of host compounds, and de novo microbial biosynthetic pathways. They function not only as nutritional products but also as signaling molecules and modulators of host physiology**,** thereby providing a new framework for pharmacological intervention. The most extensively studied categories include short-chain fatty acids (SCFAs), bile acid derivatives, tryptophan catabolites, polyamines, and vitamins**,** along with secondary metabolites such as phenolic acids and conjugated fatty acids.

Short-Chain Fatty Acids (SCFAs)

SCFAs, particularly acetate, propionate, and butyrate, are the major products of anaerobic fermentation of dietary fibers and resistant starches by gut bacteria [9]. These metabolites play pivotal roles in host energy metabolism, providing up to 10% of daily caloric requirements [10]. From a pharmacological perspective, SCFAs act as ligands for G-protein–coupled receptors (GPR41, GPR43, and GPR109A), regulate gene expression through histone deacetylase (HDAC) inhibition, and influence host immunity by modulating the differentiation of regulatory T cells [11]. Butyrate, in particular, has been shown to exert anticarcinogenic properties through epigenetic regulation of tumor suppressor genes and induction of apoptosis in colon cancer cells [12]. Propionate influences gluconeogenesis and lipid metabolism, contributing to improved insulin sensitivity [13]. Acetate, the most abundant SCFA, is a precursor for cholesterol and fatty acid synthesis and has been linked to appetite regulation via central nervous system

signaling [14]. Collectively, SCFAs highlight the pharmacological relevance of diet–microbiome interactions in metabolic and inflammatory diseases.

Bile Acid Derivatives

Primary bile acids synthesized in the liver are modified by gut microbes into secondary bile acids such as deoxycholic acid, lithocholic acid, and ursodeoxycholic acid [15]. These microbial transformations include deconjugation, dehydroxylation, and dehydrogenation reactions, primarily mediated by bacterial bile salt hydrolases. Bile acid derivatives act as potent signaling molecules that regulate host metabolism through nuclear receptors such as farnesoid X receptor (FXR) and pregnane X receptor (PXR), as well as the membrane receptor TGR5 [16]. Activation of FXR has been shown to improve glucose and lipid metabolism, while TGR5 signaling promotes energy expenditure and reduces inflammation [17]. Secondary bile acids also display antimicrobial activity by modulating intestinal microbial composition, thereby indirectly shaping host immunity [18]. Pharmacological interventions targeting bile acid signaling pathways are currently under clinical development for metabolic syndrome, type 2 diabetes, and non-alcoholic fatty liver disease (NAFLD) [19]. These findings underscore the therapeutic potential of microbiota-derived bile acid metabolites.

Tryptophan Catabolites

Tryptophan is metabolized by intestinal microbes into a diverse set of compounds, including indoles, kynurenine pathway intermediates, and serotonin precursors [20]. Indole derivatives, such as indole-3-acetic acid and indole-3-propionic acid, act as ligands for the aryl hydrocarbon receptor (AhR), thereby regulating mucosal immunity, gut barrier integrity, and epithelial repair [21]. Microbiota-mediated tryptophan metabolism is closely linked to the gut–brain axis, as indole compounds modulate serotonergic signaling and influence mood, cognition, and neuroinflammation [22]. Alterations in tryptophan metabolism have been implicated in neurodegenerative disorders (e.g., Alzheimer's, Parkinson's disease), psychiatric conditions (e.g., depression), and inflammatory bowel diseases [23]. Notably, kynurenine pathway metabolites influence NMDA receptor signaling, suggesting therapeutic potential for microbiota-modulated tryptophan catabolites in neuropharmacology [24].

Polyamines

Polyamines, such as putrescine, spermidine, and spermine, are polycationic metabolites produced by both host and microbial pathways [25]. They regulate fundamental cellular processes including DNA stabilization, protein synthesis, ion channel function, and autophagy [26]. Spermidine has attracted significant attention due to its reported anti-aging, neuroprotective, and cardioprotective **effects** in experimental studies [27]. From a pharmacological perspective, polyamines modulate inflammatory responses by regulating macrophage activity and cytokine production [28]. Dysregulation of polyamine metabolism has been associated with colorectal cancer, metabolic syndrome, and neurodegenerative diseases, positioning them as both potential biomarkers and therapeutic targets [29].

Vitamins and Other Metabolites

Gut microbiota contribute significantly to the biosynthesis of essential vitamins, including vitamin K2 (menaquinones), vitamin B12, biotin, folate, riboflavin, and nicotinic acid [30]. These microbial-derived vitamins play vital roles in coagulation, hematopoiesis, neuronal function, and energy metabolism [31]. Deficiencies in microbiota-mediated vitamin production have been associated with anemia, neuropathy, and impaired immune responses.

Additionally, the microbial metabolism of dietary polyphenols generates phenolic acids, urolithins, and conjugated linoleic acids (CLAs), which display potent antioxidant, anti-inflammatory, and cardioprotective effects [32]. These compounds are currently being investigated as nutraceuticals and pharmacological agents for chronic metabolic and cardiovascular disorders [33].

Mechanisms of Pharmacological Action of Gut Microbiota–Derived Metabolites

Gut microbiota–derived metabolites exert their pharmacological influence through multiple interconnected mechanisms that modulate host physiology, immunity, and neural functions. These mechanisms can be broadly

categorized into immune modulation, metabolic regulation, gut–brain axis signaling, and epigenetic regulation. By engaging with host receptors, enzymes, and signaling pathways, these metabolites serve as endogenous regulators with drug-like properties.

Immune Modulation

Microbiota-derived metabolites strongly influence both innate and adaptive immune responses.

- SCFAs such as acetate, propionate, and butyrate promote the expansion of regulatory T cells (Tregs) by inhibiting histone deacetylases (HDACs) and activating G-protein–coupled receptors (GPR43, GPR109A) [34].
- Butyrate enhances intestinal barrier integrity by upregulating tight junction proteins and inducing antimicrobial peptide expression, thereby reducing systemic inflammation [35].
- Tryptophan metabolites, particularly indole-3-aldehyde, act as ligands for the aryl hydrocarbon receptor (AhR), leading to increased IL-22 secretion and improved mucosal defense [36].
- Secondary bile acids regulate immune function by activating FXR and TGR5, which suppress pro-inflammatory cytokine release and promote anti-inflammatory macrophage polarization [37].
- These mechanisms demonstrate how microbial metabolites act as immune modulators, suggesting therapeutic applications in inflammatory bowel disease (IBD), autoimmune disorders, and allergies.

Metabolic Regulation

Gut microbial metabolites profoundly influence energy balance, glucose homeostasis, and lipid metabolism.

- Propionate promotes intestinal gluconeogenesis, which improves insulin sensitivity and glucose tolerance [38].
- Acetate regulates appetite by crossing the blood–brain barrier and modulating hypothalamic centers involved in satiety [39].
- Bile acid derivatives activate FXR, which reduces hepatic gluconeogenesis and lipogenesis, while TGR5 signaling enhances mitochondrial function and brown adipose tissue thermogenesis [40].
- Polyamines, such as spermidine, promote autophagy and mitochondrial function, protecting against metabolic decline and aging-related disorders [41].
- Collectively, these actions highlight how microbial metabolites regulate host metabolism in a hormone-like manner, paving the way for novel therapeutics against obesity, diabetes, and non-alcoholic fatty liver disease (NAFLD).

Gut–Brain Axis Signaling

The gut microbiota communicates with the central nervous system through metabolites that affect neurotransmission, neuroinflammation, and behavior.

- SCFAs such as butyrate influence brain function by inhibiting HDACs, increasing brain-derived neurotrophic factor (BDNF), and reducing microglial activation [42].
- Tryptophan-derived indoles cross the blood–brain barrier and regulate serotonin synthesis, linking gut microbiota to mood regulation and depression [43].
- Kynurenine pathway metabolites influence NMDA receptor signaling, which has implications for schizophrenia, Alzheimer's disease, and Parkinson's disease [44].
- Polyamines modulate ion channels and synaptic plasticity, thereby impacting learning, memory, and neurodegeneration [45].
- These findings position gut microbial metabolites as critical neuroactive compounds with therapeutic potential in neuropsychiatric and neurodegenerative diseases.

Epigenetic Regulation

One of the most fascinating aspects of microbiota-derived metabolites is their ability to modulate host epigenetics.

- Butyrate and propionate act as HDAC inhibitors, leading to histone acetylation and the activation of tumor suppressor genes in colorectal cancer [46].
- Microbial folate and vitamin B12 regulate DNA methylation through one-carbon metabolism, affecting gene expression and disease susceptibility [47].

- Polyamines influence chromatin structure and stabilize nucleic acids, contributing to epigenetic control of cell growth and differentiation [48].
- Epigenetic modifications mediated by microbial metabolites provide a molecular link between diet, microbiota, and long-term disease outcomes**,** offering a promising area for drug repurposing and personalized nutrition.

Drug Discovery and Repurposing Opportunities from Microbiota-Derived Metabolites

The gut microbiota represents an untapped reservoir of bioactive compounds with significant potential for drug discovery and repurposing. Metabolites generated by intestinal microbes can serve as endogenous ligands, enzyme modulators, and epigenetic regulators, offering opportunities to develop novel therapeutics and enhance existing drugs' efficacy. By understanding the pharmacokinetics, receptor interactions, and systemic effects of these metabolites, researchers can design microbiota-informed interventions for metabolic, inflammatory, infectious, and neurodegenerative diseases.

Microbiota Metabolites as Novel Therapeutic Scaffolds

Gut microbiota-derived metabolites such as SCFAs, indoles, secondary bile acids, and polyamines can act as direct therapeutic scaffolds.

- Butyrate analogs are being investigated for their anti-inflammatory and anticancer properties, particularly in colorectal cancer and inflammatory bowel diseases, due to their HDAC inhibition and regulatory T cell–enhancing effects [49].
- Indole derivatives are under exploration as neuroprotective and immunomodulatory agents, targeting AhR and NMDA receptor pathways, which could inform the design of new antidepressants or cognitive enhancers [50].
- Secondary bile acids can be modified to selectively target FXR and TGR5 receptors, offering potential therapies for NAFLD, type 2 diabetes, and dyslipidemia [51].
- These scaffolds provide a natural chemical diversity distinct from synthetic libraries, making them highly attractive for drug development.

Microbiota-Informed Drug Repurposing

Microbiota-derived metabolites can influence the pharmacokinetics and pharmacodynamics of existing drugs, opening opportunities for drug repurposing.

- Certain SCFAs enhance metformin efficacy by modulating gut microbiota composition and promoting SCFA production, suggesting combinatory strategies for metabolic syndrome management [52].
- Microbial metabolism can convert dietary compounds or pharmaceuticals into bioactive derivatives with new therapeutic properties. For example, the microbiota-mediated conversion of ellagic acid into urolithins has revealed anti-inflammatory and neuroprotective effects previously unrecognized in the parent compound [53].
- Secondary bile acids have been shown to modulate chemotherapeutic drug resistance, potentially allowing existing drugs to be repurposed with improved efficacy and reduced toxicity [54].
- Integrating microbiota metabolite profiles into drug repurposing pipelines may optimize therapeutic efficacy and minimize adverse effects, representing a precision medicine approach.

Microbiota-Guided Target Identification

Metabolite–receptor interactions provide insights into novel drug targets:

- SCFAs' interaction with GPR41 and GPR43 has identified potential targets for obesity, diabetes, and inflammatory disorders [55].
- Tryptophan catabolites interacting with AhR reveal therapeutic targets in neuroinflammation and gut barrier integrity [56].
- Bile acid derivatives targeting FXR/TGR5 inform metabolic disease interventions [57].
- These observations allow rational drug design informed by host–microbe co-metabolism, enhancing specificity and efficacy.

Translational and Clinical Implications

The clinical translation of microbiota-derived metabolites is gaining momentum:

- Probiotic and prebiotic interventions aim to modulate metabolite profiles, indirectly providing therapeutic benefits [58].
- Fecal microbiota transplantation (FMT) demonstrates that altering microbial composition can restore beneficial metabolites, improving outcomes in Clostridioides difficile infection, metabolic syndrome, and neurodegenerative diseases [59].
- Personalized medicine approaches incorporating microbiota metabolomic profiling allow tailored interventions, predicting drug response and minimizing adverse effects [60].
- Overall, microbiota-derived metabolites offer a dual strategy: as direct therapeutic agents and as adjuncts to optimize existing drugs, thus representing a new frontier in drug discovery and repurposing.

DISCUSSION

The evidence gathered from recent studies emphasizes the central role of diet and probiotics in shaping gut microbiota composition and its subsequent impact on host health. Findings consistently show that nutritional interventions not only modulate microbial diversity but also enhance metabolic and immune functions.

Dietary Fibers and Short-Chain Fatty Acids

Fiber-rich diets promote the growth of commensal bacteria that ferment indigestible carbohydrates to yield short-chain fatty acids (SCFAs), such as butyrate, acetate, and propionate. These metabolites contribute to intestinal barrier integrity, regulate inflammatory responses, and improve insulin sensitivity. As shown in **Table 3**, incorporation of whole grains, legumes, fruits, and vegetables significantly enhances microbial richness and favors the abundance of *Bifidobacterium* and *Lactobacillus* species, both of which are critical for maintaining immune tolerance.

Probiotics and Immune Regulation

Probiotic strains, particularly *Lactobacillus* and *Bifidobacterium*, exert beneficial effects on gut health by reinforcing epithelial barrier function and modulating immune responses. These species increase the production of antimicrobial peptides, reduce pro-inflammatory cytokines, and stimulate regulatory T-cells, which collectively lower the risk of inflammatory and metabolic disorders. Several randomized clinical trials have shown that multi-strain formulations improve irritable bowel syndrome symptoms and enhance host immunity, especially when combined with prebiotic dietary fibers (Figure 1).

Polyphenols and Omega-3 Fatty Acids

Dietary bioactives, such as polyphenols (from green tea, berries, and cocoa) and omega-3 fatty acids (from fish and flaxseed oils), selectively enrich beneficial taxa while suppressing pathogenic species. Polyphenols are metabolized by colonic microbes into bioactive metabolites with antioxidant and anti-inflammatory properties. Similarly, omega-3 fatty acids enhance SCFA production and reduce intestinal inflammation, contributing to improved cardiovascular and metabolic outcomes.

Genetically Engineered Probiotics

Emerging work highlights the potential of genetically modified probiotic strains in targeted therapy. Engineered *Lactococcus lactis* has been used to deliver anti-inflammatory cytokines directly to the gut, while modified *E. coli Nissle 1917* strains have been tested for regulating intestinal dysbiosis. These approaches represent a forward-looking strategy to customize gut microbiota modulation for personalized nutrition and precision medicine.

Challenges and Limitations

Despite compelling pharmacological promise, translating gut microbiota–derived metabolites into therapies faces several hurdles.

Inter-individual variability and context dependence

Inter-individual differences in community composition, strain-level gene content, diet, medications, and geography lead to heterogeneous metabolite profiles and responses to interventions. Population-scale studies show large interpersonal dispersion and only modestly stable "enterotype-like" structures, complicating biomarker generalization and dose standardization [61, 62]. Host genetics and immune tone further shape metabolite exposure and signaling, adding layers of context dependence to pharmacodynamics [63].

Causality versus correlation

Many associations between metabolites and disease phenotypes are correlative. Inferring causality is difficult because microbial changes can be both drivers and consequences of disease. Elegant human studies demonstrate highly personalized glycemic responses to diet that are partially predictable from the microbiome, but still rely on observational models and need mechanistic validation [64]. Some interventions (e.g., non-caloric sweeteners) reveal microbiome-mediated metabolic effects in specific subgroups, underscoring heterogeneity and the need for stratified trials [65].

Measurement, standardization, and reproducibility

Untargeted metabolomics suffers from batch effects, ion suppression, and incomplete compound identification; these technical issues limit cross-study comparability and accurate quantitation for pharmacokinetic modeling [66, 67]. Reference materials, rigorous QC, and standardized sample handling are essential but not uniformly adopted across microbiome–metabolome studies [66].

Model limitations (in vitro, in vivo, ex vivo)

Gnotobiotic mice and reductionist co-cultures enable mechanistic work but incompletely recapitulate human diet, immune context, enterohepatic circulation, and lifespan; many mouse findings fail to transfer quantitatively to humans [68]. A substantial fraction of gut taxa remains difficult to culture, although culturomics is expanding the accessible diversity; this constrains functional testing for metabolite biosynthesis and signaling [69, 70].

Safety and off-target effects

Some secondary bile acids (e.g., lithocholic acid) exhibit cytotoxic and cholestatic properties at higher concentrations, raising safety concerns for direct supplementation and necessitating careful receptor-biased or prodrug designs [71]. Clinical experience with fecal microbiota transplantation (FMT) has revealed rare but serious adverse events, including transmission of multidrug-resistant organisms, underscoring the need for stringent donor screening and regulated manufacturing when the therapeutic goal is to modulate metabolite exposure [72].

Regulatory, IP, and trial design challenges

Live biotherapeutics, engineered probiotics, and postbiotic/metabolite products occupy evolving regulatory categories with specific CMC (chemistry, manufacturing, controls) expectations and potency assays that are not yet standardized globally [73]. Trial designs must incorporate metabolomic endpoints, diet control, and microbiome stratification to detect true pharmacological signals amid noise [61, 64].

Future Perspectives

Precision pharmacology via multi-omics integration

Combining metagenomics, metatranscriptomics, proteomics, and targeted metabolomics with clinical covariates will enable individualized exposure–response models for key metabolites (e.g., SCFAs, bile acid pools, indole

derivatives). Community-level flux can be quantified using stable-isotope tracing to link dietary precursors to circulating metabolites and tissue uptake for systems-PK/PD modeling [74].

Single-cell and spatial readouts

Emerging single-cell and spatial metabolomics approaches can localize metabolite–receptor interactions in gut mucosa and liver, resolving cell-type–specific pharmacodynamics and off-targets that are invisible to bulk assays [75].

Advanced human-relevant platforms

Human intestinal organoids and microphysiological systems (gut–liver "organ-on-chip") co-cultured with select commensals allow controlled, scalable testing of metabolite signaling, transporters, and first-pass biotransformation, narrowing the mouse-to-human translation gap [76].

Rational design: postbiotics, mimetics, and biased agonism

Rather than administering raw metabolites with pleiotropic effects, postbiotics (defined, inanimate microbial preparations and/or purified microbial molecules) offer doseable, stable agents with clearer CMC paths [77]. Medicinal chemistry can yield metabolite mimetics **or** biased agonists (e.g., FXR/TGR5-selective ligands; AhR-biased indoles) that preserve efficacy while limiting toxicity [71].

Engineered consortia and synthetic biology

Engineered commensals and defined consortia can deliver metabolites in situ, respond to disease signals, and self-limit. Proof-of-concepts show programmable diagnostic and therapeutic functions in the gut, foreshadowing combination regimens that pair a drug with a metabolite-generating chassis [78].

AI/ML for discovery and trial enrichment

Machine-learning models trained on microbiome + metabolome features improve phenotype prediction, target priors, and trial stratification. Large, harmonized datasets will enable causal discovery and digital twin simulations of diet–microbiome–metabolite–host networks to prioritize interventions and responders before costly trials [79].

Enterotype-guided and diet-anchored clinical trials

Prospective studies should incorporate enterotype- or pathway-based stratification, standardized diets, and adaptive designs to account for response heterogeneity and maximize power to detect metabolite-mediated pharmacological effects [61, 62, 64].

CONCLUSION

Gut microbiota derived metabolites constitute a rich, endogenous pharmacopeia that engages host GPCRs, nuclear receptors, ion channels, and epigenetic machinery. Robust evidence supports their roles in immune modulation, metabolic control, gut–brain signaling, and chromatin regulation, positioning them as both direct therapeutic scaffolds and adjuncts that enhance or reshape responses to existing drugs. Key translational barriers human variability, causal inference, analytic standardization, model fidelity, and safety are increasingly tractable with multi-omics integration, human-relevant models, synthetic biology, and AI-assisted trial design. Moving forward, precision, safety-first development of postbiotics and receptor-biased mimetics, coupled with stratified clinical trials, can convert this mechanistic insight into clinically reliable therapies. In sum, the pharmacology of microbiota-derived metabolites marks a new frontier for drug discovery and repurposing that is scientifically mature enough to justify focused, well-controlled human studies.

Table 1. Key Gut Microbiota–Derived Metabolites and Their Pharmacological Roles

S.no	Metabolite	Microbial Source	Pharmacological Role	Target Pathway/Mechanism	References
1	Short-chain fatty acids (SCFAs: acetate, propionate, butyrate)	Firmicutes, Bacteroidetes	Anti-inflammatory, gut barrier strengthening, energy metabolism	G-protein coupled receptors (GPR41, GPR43), HDAC inhibition	[1–3]
2	Tryptophan metabolites (indoles, kynurenine)	Lactobacillus, Clostridium	Neuroprotective, immune modulation	Aryl hydrocarbon receptor (AhR), serotonin pathway	[4–6]
3	Secondary bile acids	Clostridium, Bacteroides	Cholesterol metabolism, anticancer	FXR, TGR5 signaling	[7,8]
4	Polyphenol-derived metabolites	Bifidobacterium, Lactobacillus	Antioxidant, cardioprotective	Nrf2 activation, endothelial function	[9,10]
5	Trimethylamine N-oxide (TMAO)	Enterobacteriaceae	Pro-atherogenic	Platelet hyperreactivity, vascular inflammation	[11]

Table 2. Applications of Gut Microbiota–Derived Metabolites in Drug Repurposing

S.No	Metabolite	Repurposing Application	Target Disease/Condition	Mechanistic Basis	References
1.	Butyrate (SCFA)	Repurposed as neuroprotective adjunct	Alzheimer's disease, depression	Enhances histone acetylation, promotes neurotrophic factors, anti-inflammatory	[12–14]
2.	Propionate (SCFA)	Repurposed for metabolic regulation	Obesity, type-2 diabetes	Activates GPR41/GPR43, modulates insulin sensitivity	[15,16]
3.	Indole-3-propionic acid (Tryptophan metabolite)	Repurposed as antioxidant	Neurodegenerative disorders	Free radical scavenging, mitochondrial protection	[17,18]
4.	Secondary bile acids	Repurposed for oncology	Colorectal and liver cancer	FXR/TGR5 signaling, apoptosis modulation	[19,20]
5.	Urolithins (Polyphenol metabolites)	Repurposed for anti-aging therapies	Sarcopenia, neurodegeneration	Induction of mitophagy, anti-inflammatory effects	[21,22]
6.	Trimethylamine N-oxide (TMAO) inhibitors	Repurposed as cardioprotective agents	Atherosclerosis, thrombosis	Reduces platelet hyperreactivity and vascular inflammation	[23,24]

Table 3. Dietary and Probiotic Interventions Affecting Gut Microbiota and Host Health

S.No	Intervention	Main Microbial Effect	Health Outcome	Reference
1	High-fiber diet	↑ *Bifidobacterium*, ↑ *Lactobacillus*	↑ SCFA production, improved insulin sensitivity	[1,2]
2	Probiotic supplementation	↑ Gut integrity, ↓ Pro-inflammatory cytokines	Better immune regulation, reduced gut inflammation	[3,4]
3	Polyphenol-rich diet	↑ Beneficial taxa, ↓ Pathogenic bacteria	Antioxidant activity, reduced oxidative stress	[5]
4	Omega-3 fatty acid intake	↑ SCFAs, ↓ Inflammatory markers	Improved metabolic and cardiovascular outcomes	[6,7]
5	Genetically engineered probiotics	Targeted microbial modulation	Personalized treatment for gut dysbiosis	[8]

ABSTRACT

This study focuses on the advancement of mathematical modelling of magnetohydrodynamic fluid flow in the direction of a stretching sheet. Also focused the following physical parameters in addition to the magnetic field parameter: the thermal radiation parameter, the Soret number, the Prandtl number, the Schmidt number, and the Dufour number. By applying similarity transformations, the governing partial differential equations are reduced to a system of ordinary differential equations, which are subsequently solved using the Runge–Kutta method to obtain the final numerical solutions. Numerical representations for the velocity profile, temperature profile, and concentration profile were produced the physical parameters for specific values. Additionally, The Sherwood, Nusselt, and Skin-friction coefficients' numerical values are tabulated and the graphical representation, A numerical comparison is also presented with previously published data for program code validation

INTRODUCTION

Many researchers have taken into account and considered the nature and engineering ([1],[2])) have a large number of free convective flow experience. When heat and mass transfer take place simultaneously, the interaction between the fluxes complicates the driving potential. Energy flow is influenced not only by temperature gradients but also by

concentration gradients. The energy flux generated due to a concentration gradient is referred to as the diffusion–thermo or Dufour effect. Conversely, temperature gradients can give rise to mass flux, a phenomenon described as the Soret or thermal diffusion effect. In most heat and mass transfer scenarios, these cross-diffusion effects are negligible compared to Fourier's and Fick's laws. However, exceptions exist—for instance, thermal diffusion plays a crucial role in isotope separation and in mixtures of gases with significantly different molecular weights, such as hydrogen-helium and nitrogen-air (Kafoussias and Williams [3]). The influence of cross-diffusion has been examined under various flow conditions, including aiding, opposing, and mixed convection regimes. For instance, Srinivasacharya *et al*. [4] investigated mixed convective heat and mass transfer over a wavy surface embedded in a Darcy porous medium. Hayat *et al*. [5] investigated the three-dimensional Soret and Dufour effects on an exponentially stretching porous surface in the presence of chemical reactions and heat generation/absorption. Similarly, Makinde and Olanrewaju [6] analyzed steady mixed convection in a chemically reacting MHD flow past a vertical porous plate, incorporating the influences of the Soret and Dufour effects. Furthermore, Makinde [7] analyzed MHD mixed convection in a porous medium with the inclusion of thermal diffusion (Soret effect) and diffusion-thermo (Dufour effect). Olanrewaju and Makinde [8] examined these effects in an MHD boundary layer flow with suction/injection. Makinde *et al*. [9] numerically analyzed chemically reactive hydromagnetic flow with heat source/sink and Dufour effects. Additionally, Pal and Mondal [10] investigated mixed convection with thermal radiation and chemical reactions in a Darcian porous medium. Inspired by these studies and the practical applications (e.g., isotope separation), this work focuses on the combined effects of Soret (thermal diffusion) and Dufour (diffusion thermo) on MHD free convective boundary layer flow over a stretching sheet with thermal radiation. The study extends Mabood *et al*.'s [11] work by considering a more generalized MHD boundary layer flow of a viscous incompressible fluid over an exponentially stretching surface. Relevant research in this field can be found in [12]– [19], while [20]– [29] provide foundational insights into the problem. Additionally, the authors [30]–[38] have contributed finite element method (FEM) solutions for various heat and mass transfer scenarios. The momentum, thermal, and solutal boundary layer equations are translated to ordinary differential equations and solved using the Runge-Kutta method. The results of this analysis indicate that the flow field is significantly affected by the magnetic field parameter, as well as by the Dufour and Soret numbers at the wall. The selected results for the velocity, temperature and concentration components are graphically represented in order to demonstrate the tendency of the solutions. The remainder of the document shall be structured in the following manner. The problem is set out in Section 2, the solutions by method is defined in Section 3. Section 4 discusses validation of software code. Discussion of graphical results are discussed in Section 5. Finally, Section 6 represents the brief conclusions of this research work.

Design of the problem

Dufour and Soret's combined effects on thermal diffusion (thermal diffusion) are investigated in this paper on a steady, 2-dimensional radiating flow of an incompressible, viscous, and electrically conducting fluid induced by stretching sheet when present of buoyancy force and magnetic field effects. In Fig. 1, you can see how this study work's physical configuration is organised, the following assumptions are assumed.

i. Suppose that the plate with the surface temperature T_w be immersed within a quiescent fluid with a constant ambient temperature T_∞.
ii. The sheet surface is often to a fluctuating magnetic field B (x) when MHD flow occurs at a modest magnetic Reynolds number, whereas the induced magnetic field is very small. In the case of MHD flow with a low magnetic Reynolds number, this can be justified.

The flow also heat transfer through Soret, Dufour, and radiation impact be governed by the dimensional type of equations shown in the following figure using boundary layer approximations. Physical model and Coordinate system (Fig.1).

Governing Continuity Equation

$$\left(\frac{\partial u}{\partial x}\right)+\left(\frac{\partial v}{\partial y}\right).=0 \tag{1}$$

Governing Momentum Equation

$$\left(\frac{\partial u}{\partial x}\right)u+\left(\frac{\partial u}{\partial y}\right)v=-u\left(\frac{B_0^2\sigma}{\rho}\right)+v\left(\frac{\partial^2 u}{\partial y^2}\right) \tag{2}$$

Equation of thermal energy

$$u\left(\frac{\partial T}{\partial x}\right)+v\left(\frac{\partial T}{\partial y}\right)=\alpha\left(\frac{\partial^2 T}{\partial y^2}\right)-\frac{1}{\rho C_p}\left(\frac{\partial q_r}{\partial y}\right)+\frac{D_m K_T}{C_s C_p}\left(\frac{\partial^2 C}{\partial y^2}\right) \tag{3}$$

Equation of species concentration

$$\left(\frac{\partial C}{\partial x}\right)u+\left(\frac{\partial C}{\partial y}\right)v=D_m\left(\frac{\partial^2 C}{\partial y^2}\right)+\left(\frac{K_\Gamma D_m}{T_m}\right)\left(\frac{\partial^2 T}{\partial y^2}\right) \tag{4}$$

The following are the flow's boundary conditions

$$\left.\begin{array}{l} u=U_w(x)=U_o e^{\frac{x}{L}},\ v=0,\ T_w(x)=T_\infty+T_o e^{\frac{x}{2L}},\ C_w(x)=C_\infty+C_o e^{\frac{x}{2L}}\ \ at\ \ y=0 \\ u\to 0,\ T\to T_\infty,\ C\to C_\infty\ \ as\ \ y\to\infty \end{array}\right\} \tag{5}$$

The magnetic field is considered

$$B(x)=B_o e^{\frac{x}{2L}} \tag{6}$$

We have used the Rosseland approximation for radiation ([39])

$$q_r=-\frac{4\sigma}{3k^*}\left(\frac{\partial T^4}{\partial y}\right) \tag{7}$$

Suppose in the flow, there is a temperature difference we expand T^4 in a Taylor series on T_∞, and ignored terms of higher order, we get

$$T^4\approx 4T_\infty^3 T-3T_\infty^4 \tag{8}$$

Using (7), eq. (4) We've got,

$$u\left(\frac{\partial T}{\partial x}\right)+v\left(\frac{\partial T}{\partial y}\right)=\alpha\left(\frac{\partial^2 T}{\partial y^2}\right)-\frac{16\sigma T_\infty^3}{3\rho k^* C_p}\left(\frac{\partial^2 T}{\partial y^2}\right)+\frac{D_m K_T}{C_s C_p}\left(\frac{\partial^2 C}{\partial y^2}\right) \tag{9}$$

The equation of continuity is simplified by using a stream function (1) is satisfied

$$u=\frac{\partial\psi}{\partial y}\ \text{ and }\ v=-\frac{\partial\psi}{\partial x}$$

where $$\psi(x,y)=\left[\sqrt{(2\nu L U_o)}\right]e^{\left(\frac{x}{2L}\right)}f(\eta) \tag{10}$$

The following transformations are introduced for non-dimensionalized forms of momentum, energy, also concentration equations, as well as boundary conditions.

$$\left.\begin{aligned}\eta = y\left(\sqrt{\frac{U_o}{2\nu L}}\right)e^{\left(\frac{x}{2L}\right)},\ v = -\left(\sqrt{\frac{\nu U_o}{2L}}\right)e^{\left(\frac{x}{2L}\right)}\left\{f(\eta)+\eta f'(\eta)\right\},\\ u = U_o e^{\left(\frac{x}{L}\right)}f'(\eta),\ T = T_\infty + T_o e^{\left(\frac{x}{2L}\right)}\theta(\eta),\ C = C_\infty + C_o e^{\left(\frac{x}{2L}\right)}\phi(\eta)\end{aligned}\right\} \quad (11)$$

Using Eq. (11), the fundamental Eqs. (1) to (5) become

$$f''' + ff'' - 2f'^2 - Mf' = 0 \quad (12)$$

$$\frac{1}{\Pr}\left(1+\frac{4R}{3}\right)\theta'' + f\theta' - f'\theta + Du\phi'' = 0 \quad (13)$$

$$\phi'' + Scf\phi' - Scf'\phi + SrSc\theta'' = 0 \quad (14)$$

As well as the associated boundary conditions (5) transform into

$$\left.\begin{aligned}f = 0,\ f' = 1,\ \theta = 1,\ \phi = 1\ at\ \eta = 0\\ f' \to 0,\ \theta \to 0,\ \phi \to 0\ as\ \eta \to \infty\end{aligned}\right\} \quad (15)$$

Here the physical parameters involved are defined as

$$\left.\begin{aligned}\Pr = \frac{\nu}{\alpha},\ M = \frac{2\sigma B_o^2 L}{\rho U_o},\ R = \frac{4\sigma T_\infty^3}{k^*\kappa},\ Sc = \frac{\nu}{D_m},\ Sr = \frac{D_m K_T(T_o - T_\infty)}{T_m\nu(C_o - C_\infty)},\ Du = \frac{D_m K_T(C_o - C_\infty)}{C_s C_p \nu(T_o - T_\infty)}\end{aligned}\right\} \quad (16)$$

Quantities of physical interest, the physical parameters of are listed below

the skin-friction coefficient (Cf), local Nusselt number (Nu_x), and local Sherwood number (Sh_x):

$$Cf\left[\sqrt{\frac{\mathrm{Re}_x}{2}}\right]e^{-\left(\frac{3x}{2}\right)} = f''(0) \quad (17)$$

$$Nu_x\left(1+\frac{4R}{3}\right)\left[\sqrt{\frac{2}{\mathrm{Re}_x}}\right]e^{-\left(\frac{x}{2}\right)} = -\left(1+\frac{4R}{3}\right)\theta'(0) \quad (18)$$

Here $\mathrm{Re}_x = \dfrac{U_o L e^{\left(\frac{x}{L}\right)}}{\nu}$ the local Reynoldbe's number.

Method of Solution by Runge-Kutta-Fehlberg method

Using an effective numerical technique, the system of coupled nonlinear Eqs. (12)-(14) is numerically solved by method of Runge-Kutta-Fehlberg. Boundary value problem system using the shooting method, Eqs. (12)-(14) are first changed into a problem with an initial value. The authors choose η_{max} = 4 (in terms of the maximum number of graphs) to ensure that our method converges for all parameters. For the sake of convergence, the accuracy of the fifth decimal place to be taken.

Program Code Validation

The present findings were compared with previously published results [11]-[13] for a variety of thermal radiation values, magnetic field, also Prandtl number (see Table-1) given the absence of numbers Soret and Dufour in order to verify their accuracy. We were able to reach a remarkable level of agreement with those solutions as a result of this table.

RESULTS AND DISCUSSIONS

A number of dimensionless flow variables such as velocity, temperature, and concentration profiles are obtained as a result of numerical calculations, and their behaviour is discussed in relation in the governing parameters' fluctuation, which are parameter of magnetic field (M), thermal radiation parameters R, Prandtl number (Pr), Schmidt numeral (Sc), Dufour number (Du), and Soretnumber (Sr). M is identical to 0.5, R is identical to 0.5, Pr is identical to 0.71, Du = 0.5, Sr is identical to 0.5, and Sc is identical to 0.22 in this study's default parametric values. To maintain consistency, all graphs are plotted in the same format, unless otherwise specified on the respective figure. *M* impact on the velocity profiles

- The influence of the magnetic parameter (M) on the dimensionless velocity is depicted in Fig. 2. For transverse velocity, it can be seen that the velocity raises steadily and then approaches the value of unity. Increasing the magnetic parameter, on the other hand, causes the nondimensional transverse velocity to decrease. A retarding Lorentz force is created when a transverse magnetic field is affected to an electrically conducting fluid, which is the reason for this. When this force is applied, it causes the fluid motion into the boundary layer to slow down, resulting in a decrease in velocity at the rate of a raise in high temperature.
- Changing the thermal radiation parameter (R) has an effect on the flow velocity depicted in Fig. 3. We find that thermal radiation promotes convective flow, which is consistent with previous findings. According to Fig. 4, because the thickness of the thermal boundary layer grows by an increase in the amount of thermal radiation present, thermal radiation has the effect of increasing heat transmission. We can see that R has the effect of raising the thermal boundary layer's temperature distribution, which corresponds to our data. This is because an raise in R leads to an increase in radiation in the thermal boundary layer, which raises the values of the thermal boundary layer's temperature profiles as a result of the increased radiation.
- Alternatively, the impact of Dufour number on variables flow such as Profiles of velocity also temperature be explained in Figs. 5 and 6. They demonstrate that increasing the Dufour number causes the fluid's temperature and velocity to rise. In the energy field, the presence of a mass concentration gradient as a result caused by the combined action of an irreversible process the Dufour effect to manifest itself. It has a tendency to increase the amount of energy that flows through the system. The flow system's temperature rises as a result of this phenomenon (see Fig. 5). To make matters worse, the increase in temperature caused because temperature is a function of flow velocity, the Dufour effect causes an increase in flow velocity (observe Fig. 6).
- The effects of the Soret number are illustrated in Figs. 7 and 8, which reveal that an increase in the Soret number enhances both the concentration and velocity of the fluid. The Soret effect originates from the presence of a temperature gradient within the concentration field, produced by an irreversible process. This mechanism enhances the concentration flux within the flow system as it evolves. This helps to explain Fig. 7. Furthermore, as the concentration of the fluid increases, the level about collision between the fluid particles raises based on proportion to the increase the fluid's concentration. Furthermore, this raises the particles' kinetic energy, which in turn increases their velocity (observe Fig. 8).
- As shown in Fig. 9a, the effects of the Prandtl number (Pr) are displayed profiles of temperature. As the Prandtl number increases, the thermal boundary layer thickness decreases significantly, leading to a steeper wall temperature gradient (in absolute terms), as shown in the figure. Fluids with high thermal conductivity are indicated by a low Prandtl number, which results in thicker thermal boundary layer structures than those produced by fluids with a low Prandtl number.
- On the graph in Figure 10, on the non-dimensional concentration profiles, the Schmidt (Sc) number's impact is shown. The concentration decreases proportionally with an increase in the Schmidt number. Consequently, the

concentration buoyancy effects are reduced, leading to a corresponding decrease in fluid velocity. The concentration profile reduction is accompanied by a decrease in the concentration boundary layers that occurs at the same time as the reduction in concentration profiles. This behaviour is clearly illustrated in Fig. 10. Skin-friction coefficient numerical values for a variety of values of *M*, Pr, *R*, *Sc*, *Sr* and *Du* (Table-2).

- Figure 1 illustrates the numerical values of the skin-friction coefficient (Cf) for different variations of the magnetic field parameter (M), Prandtl number (Pr), thermal radiation parameter (R), Schmidt number (Sc), Soret number (Sr), and Dufour number (Du). The results show that Cf increases with higher values of R,Sr, and Du, while it decreases with increasing M, Pr, and Sc.
- The effects of the Prandtl number (Pr), thermal radiation (R), and Dufour number (Du) are considered in evaluating the numerical values of the heat transfer coefficient (Nu).As the thermal radiation parameter (R), the Dufour number (Du), and the Prandtl number (Pr) grow, the rate of heat transfer coefficient (Nu) increases, as shown in table-3
- The table presents the numerical values of the mass transfer coefficient (Sherwood number, Sh) for different Schmidt number (Sc) and Soret number (Sr) values. The rate of heat transfer coefficient (N_u) increases with increasing values of the Soret number (S_r) reduce as the Schmidt number (Sc) increases, as illustrated in table – 4.

CONCLUSIONS

This research examines the combined impact of Soret, thermal radiation, and Dufour on constant, viscous, incompressible, and electrically conducting fluid flow across a stretched sheet in the magnetic field presence. The fundamental governing equations can be reduced and rically solved via similarity transformation, with the results shown graphically using the R-K technique. The following are the investigation's findings:

- *Du raises* the Skin-friction and Nusselt number coefficients, the velocity and temperature profiles
- M reduces velocity profile in addition to the Skin-friction coefficients.
- S_r raise velocity also concentration profiles, with Skin-friction coefficients and Sherwood number coefficients are also included.
- P_r reduces the temperature profiles and Skin-friction coefficient while increases the Nusselt number coefficient.
- S_c reduces the Sherwood number coefficient as well as the concentration profiles.
- R An increase in R enhances the skin-friction coefficient, the Nusselt number, as well as the velocity and temperature profiles.
- To conclude, the numerical results obtained in this study are compared with previously published data, showing excellent agreement.

ABSTRACT

Kadaknath, a native poultry breed glorified as "Black Gold" because of its special black plumage colour, high quality meat and better adaptability has also recently gained importance in West Bengal in districts of Paschim Bardhaman (Asansol), South 24 Parganas and Bankura respectively. The present study was conducted to understand the management practices, perceptions and challenges of farmers on Kadaknath rearing in those regions as well as the farmers need assessment on the same. In survey areas, a total of nine blocks (three each from geographically closer districts of Paschim Bardhaman, South 24 Parganas, and Bankura districts) were chosen based on concentration of Kadaknath poultry farmers — Barabani, Jamuria and Salanpur from Paschim Bardhaman; Canning, Diamond Harbour and Kultali from South 24 Parganas; and Indpur, Onda and Taldangra from Bankura, respectively. Out of each block, three villages were picked randomly and from each of the villager 10 farmers were surveyed making a total sample of 270 respondents. Under local rearing conditions, the body weight of adult Kadaknath females averaged approximately 1.1 kgmales averaged 1.4 kg. The findings indicated an overall positive attitude among farmers with regards to Kadaknath rearing, with 61.85% of the participants having a favorable attitude which can be attributed to the potential for income generation and the adaptability of Kadaknath in the humid subtropical climate of West Bengal. The breed was viewed by farmers as profitable due to its good market price, high disease resistance, and good backyard performance with low input. Low brooding ability, susceptibility of chicks to Ranikhet disease, and lack of veterinary service were noted as the major constraints. Abstract Overall, the results indicate the potential of Kadaknath poultry in improving rural livelihoods through its adoption in both potentially suitable districts, but also suggest that better extension services and health management strategies could further improve adoption of the breed in more districts.

Keywords: Kadaknath poultry, indigenous breed, rural livelihoods, West Bengal, farmer perception

INTRODUCTION

Kadaknath, a rare indigenous poultry breed endemic to Madhya Pradesh with a nearly completely black skin, feathers, meat, and viscera caused by fibro melanosis (Jaishankar *et al*. 2020). Known as Kala Masi, this breed has started becoming popular in some parts of West Bengal, particularly in Paschim Bardhaman (Asansol region), South 24 Paraganas and Bankura districts, as small and marginal farmers have started rearing Kadaknath for livelihood sustainability. The black color of the Kadaknath, as part of hyperpigmentation, is not merely an aesthetic and cultural property after all the color linked to the unique nutritious meat properties of the bird (Haunshi *et al*., 2021). The breed has been classified into three color types—Jet Black, Pencilled, and Golden—each of which has shown similar capacity and adaptability to withstand backyard conditions (Parmar *et al*., 2006).Kadaknath Rearing trials have been successfully performed in the agro-climatic zones of Paschim Bardhaman, South 24 Parganas, and Bankura where Kadaknath has been found to be tolerating ambient temperature variation, humidity and exposure to diseases. The high market price associated with Kadaknath, along with its fine meat palatability, low fat content and higher protein content (~25% compared to 18% in normal broiler meat (Pathak *et al*., 2006)) have attracted farmers from these districts. It is said that the meat and eggs are high in iron and amino acids which serve as an addition in nutrition for local consumers (Ezhil Valavan *et al*., 2016) In addition, the breed has the adaptability to local feeding system such as kitchen waste, azolla and grains like maize and soybean, which make it economic viable (Mohan *et al*., 2008).In terms of culture, the households in rural areas from the selected districts of the study have the economic income generation as well as the mental as a symbol of health and vigor by means of Kadaknath. The demand for this species has further increased among urban consumers and niche markets due to the high reputation of its medicinal and aphrodisiac properties (Haunshi *et al*., 2021). This multidimensional advantage has now made Kadaknath poultry farming an integral part of the strategies for rural development and nutritional security in Paschim Bardhaman, South 24 Parganas and Bankura districts. The study was conducted in selected districts of West Bengal, namely Paschim Bardhaman (Asansol), South 24 Parganas, and Bankura (Figure 1.0).

METHODOLOGY AND METHODS

The current study was conducted focusing on three districts of West Bengal namely Paschim Bardhaman (Asansol), South 24 Parganas and Bankura, which have attracted recently for the sustainable rural enterprise through the rearing of Kadaknath poultry. Hence, the objectives of the study were—i) attitude of Kadaknath farmers towards rearing of Kadaknath poultry birds; ii) perception of Kadaknath farmers on management practices, productivity and economic feasibility of Kadaknath poultry rearing.

Selection of Study Area

The study areas were purposively selected where Kadaknath poultry rearers in good number and rural poultry development activities are in progress. For instance, Barabani, Jamuria and Salanpur in Paschim Bardhaman, Canning, Kultali and Diamond Harbour in South 24 Parganas and Indpur, Onda and Taldangra in Bankura. These blocks reflect a fairly wide range of agro-climatic condition and smallscale poultry rearing practices, as perceived from their examination in earlier surveys on the indigenous breeds (Parmar *et al*., 2006; Mohan *et al*., 2008).

Sampling Procedure

Then, we selected randomly three villages from each of selected blocks and thus covered 27 villages in 3 districts. In total, a random sampling technique was applied to identify 10 Kadaknath poultry farmers per village, which leads to a sample size of 270 respondents. Stratified random sampling was used to achieve representation from different socio-economic and environmental conditions (Jaishankar *et al*., 2020; Haunshi *et al*., 2021).

Data Collection

Primary Data was collected using pre-tested structured interview schedule using Personal interviews. It has been prepared in consultation with poultry scientists, veterinarians and agricultural universities in West Bengal. The

interview schedule included both closed and open-ended questions on socio-economic profile, management practices, disease management, and marketing pattern.

Measurement of Attitude and Perception

A teacher-made test was developed to assess farmers' attitudes towards Kadaknath rearing under the Likert-type five-point continuum: Strongly Agree, Agree, Undecided, Disagree, and Strongly Disagree, respectively rated as 5, 4, 3, 2, and 1 for positive statements and in reverse direction for negative statements. A pool of 30 attitude statements was elicited by consulting experts in the field and review of relevant literature (Ezhil Valavan *et al*., 2016; Pathak *et al*., 2006) and from that only 8 statements were finalized after validation by 50 poultry specialists from 28 states of India. Perception was assessed through frequency and percentage analysis of responses for economic returns, disease resistance, feed adaptability and market potential.

Data Analysis

Data obtained were tabulated and analyzed using descriptive statistical techniques i.e., frequency, mean and standard deviation to interpret the attitude and perception of farmers. Quantitative data were processed into useful information for comparisons between districts (inferred from Microsoft Excel and SPSS).The methodological framework developed in this study helped in objectively measuring socio-economic characteristics affecting the rearing of Kadaknath and the potential to adopt it as a sustainable livelihood option among the rural population of Paschim Bardhaman, South 24 Parganas and Bankura districts.

RESULTS AND DISCUSSION

Attitude of Kadaknath Farmers Towards Rearing

Attitude is the degree of positive or negative effect associated with a psychological object (a person, place, or thing) (Ajzen, 1991). A scaled attitude score reflecting the positive or negative attitude of Kadaknath farmers towards rearing of Kadaknath poultry birds were envisaged through a structured attitude scale developed and the result is given in Table 1. Results revealed that majority of the Kadaknath farmers, i.e., (62.96%) possessed favorable attitude regarding rearing of Kadaknath poultry birds, besides, the proportion of farmers with highly favorable attitude stood at 22.59% along with 14.45% with less favorable attitude. Therefore, a total of 143 (>85.55 percent) respondents exhibited either favorable or highly favorable orientation towards Kadaknath rearing. Most likely the combination of excellent management ease of the breed, climate adaptability and a strong market potential for this breed in both monopoly of regional and urban poultry markets. With its ability to withstand and resist disease and spend little on feed, Kadaknath was seen as a regular source of extra income, farmers of Paschim Bardhaman and Bankura said. Relevantly, respondents from South 24 Parganas emphasized its nutritional and medicinal importance of breed; this was concurrent with past findings of Haunshi *et al*. to (2021) and Ezhil Valavan *et al*. (2019), and Kadaknath being a potential meat for health-conscious people because of its high protein and low fat content (Sankhala *et al*.

Perception of Kadaknath Farmers

The definition of perception itself is the mental process of interpreting or making sense of stimuli (Robbins and Judge, 2019). The Table 2 shows the perception of Kadaknath farmers on different aspects of poultry production. The findings indicated that approximately 100 % of the respondents considered Kadaknath rearing as profitable and economically feasible. Farmers said Kadaknath birds provide more net returns and its meat is of quality which attracts health-conscious consumers. The breed identification of birds were performed by a large number of respondents based on the specific morphological features such as black plumage, skin, tongue, beak and legs which agrees with fibro melanosis trait described by Jaishankar *et al*. (2020) and Haunshi *et al*. (2021).In terms of resistance to diseases, most of the farmers stated that Kadaknath birds are more resistant to common poultry disease and heat stress compared to the broiler and local fowl (Table 2). Ranikhet disease was the most routinely reported infection in Kadaknath chicks, especially at the time of seasonal changes, as reported by 61.11% of the respondents. Mohan *et al* 12 reported similar observations. (2008), and stress the importance of early chick preventive care. About 96.30% of the

farmers expressed that Kadaknath birds do not need much care on being matured and can live easily with other poultry in normal backyard conditions without any housing system. Also, 95.93% respondents agreed that Kadaknath birds can be maintained in local environment for better body weight and health. On the contrary, 93.33% of respondents mentioned that the brooding tendency of Kadaknath hens is low and in natural incubation and chick rearing farmers depend on indigenous desi hens(Table5).The results suggest that Kadaknath rearing can be a sustainable and remunerative enterprise for farmers in the selected districts of Paschim Bardhaman, South 24 Parganas and Bankura, given an effective management of disease and proper care of chicks on farm. Thus, the breed could be a very important part of rural poultry development programs at different place in West Bengal by its resistance against diseases, meat quality and high demand in market.

CONCLUSION

A study conducted in the Paschim Bardhaman (Asansol), South 24 Parganas and Bankura districts of West Bengal has shown that Kadaknath poultry farming can be a sustainable and profitable livelihood option for rural farmers in the state. All the farmers in the three regions of the study had a poor impression of Kadaknath rearing with respect to its suitability, management inputs, and marketing cost, but these impressions were highly advantageous owing to the adaptability of Kadaknath, less input needed to manage the birds, and better return value. This research shows that Kadaknath birds are highly resistant to various prevalent poultry diseases and also to heat stress, as there is no significant reduction in chick or egg production during periods of high temperature. Ranikhet disease was a significant health issue, particularly for chicks during seasonal changes. Nonetheless, most farmers reported mortality rates to be lower in this breed than in commercial broiler breeds with an implication, based on farmer judgement, of a natural resistance and hardiness in the breed. Also, since the Kadaknath hen has a very low desire to brood, farmers effectively brought desi hens for natural hatching into the method. The farmers from the three districts also emphasized that under normal backyard housing and feeding conditions, general body weight and health of Kadaknath birds remain optimal, and under such conditions, an intensive rearing system involving higher costs is not necessary. Due to high market demand for Kadaknath meat in other states of India, several rural households have taken up this enterprise for livelihood diversification and income stability. The results indicate that Kadaknath poultry farming in Paschim Bardhaman, South 24 Parganas, and Bankura has great potential for economic resilience, climate adaptation and rural empowerment as part of sustainable agricultural development in the state.

ABSTRACT

On account of the concurrent evaluation of Darunavir Ethanolate (DAR) and Ritonavir (RIT) in tablet dosage form, a straightforward, specific, accurate, and precise RP-HPLC method has been devised. An Enable C18 column (250 x 4.6 mm, 5 µm particle size) and a mobile phase consisting of acetonitrile and water (80:20 v/v) at a flow rate of 1 ml/min were used to achieve the separation in this particular RP-HPLC procedure. The detection was made at 247 nm. It was found that the DAR and RIT retention times were 2.939 and 3.537 minutes, respectively. The linearity ranges for DAR and RIT are 25–125 µg/ml and 10–50 µg/ml, respectively. The proposed method was demonstrated to be simple, precise, and accurate for the concurrent estimation of DAR and RIT in their combined dose form. It can be used for regular

analysis as well. The method was validated for several characteristics, such as linearity, accuracy, precision, robustness, ruggedness, LOD, and LOQ, in accordance with ICH requirements.

Keywords: Darunavir Ethanolate; Ritonavir; RP-HPLC, Tablet dosage form, ICH.

INTRODUCTION

In pharmaceutical industry, there are various drugs which have characteristic uses. In some cases, two or more active drugs are combined results in combination dosage or fixed-dose combination (FDC) to achieve better therapy. These combination drugs provide better therapy and improve medication compliance. With greater therapeutic activity, these drugs also provide challenges in the development of analytical methods and their validation parameters. Upon investing a lot of time on research, analytical methods are developed by researchers, scholars etc., around the globe. These techniques are employed to determine a drug's identity, potency, safety, and other attributes. The molecular formula for darunavir ethanolate (DAR) is (3R,3aS,6aR)-hexahydrofuro[2,3-b].[(2S,3R)] furan-3-yl-N-[N-(2-methylpropyl)4-aminobenzenesulfonamido] -3-hydroxy-4-[[-1-phenylbutan-2yl] carbamate. Darunavir suppresses HIV-1 protease's catalytic activity by binding to and specifically targeting the enzyme's active site when taken orally.

Another powerful medication used in antiretroviral therapy is ritonavir. 1,3-thiazol-5- ylmethyl-N-[(2S,3S,5S)-3-hydroxy-5[(2S)-3-methyl-2-{[methyl({[2-(propan-2-yl)-1,3-thiazol-4- yl] methyl}) carbamoyl] amino}butanamido]1,6-diphenylhexan-2-yl] carbamate is the chemical formula for ritonavir (RIT). Ritonavir mainly acts by inhibiting HIV-1 and HIV-2 proteases thereby interferes with the reproductive cycle of HIV thus acts as a antiviral agent. These two drugs were initially developed as independent anti viral drugs but further research about these drugs revealed that these are much more effective in the antiretroviral therapy when used in combination. The literature review reveals that Darunavir and Ritonavir alone or in combination with other drugs were determined through various methods like HPLC [1-12], LC-MS/MS [13]. Only few analytical methods reported for its quantification includes LC-MS/MS [14-15] and HPLC [16-17]. We have found that there is a need for a simple yet cost effective as well as exact and reliable method. The goal of this study is to create a routine analysis of the concurrent estimation of Ritonavir and Darunavir in bulk and combination dosage forms that is easy to use, accurate, exact, and economical. For better estimation and routine analysis of a chemical entity or a drug, RP-HPLC dominates other methods with its ability to find active constituents and impurities in the sample.

MATERIALS AND METHODS

Chemicals and reagents

Darunavir ethanolate and Ritonavir with a purity > 100.1 % w/w was obtained as a gift samples and formulation of Darunavir and Ritonavir combination dosage form (DANAVIR-R) was procured from the local market, chemicals and reagents used are of analytical grade. Chemicals like acetonitrile and water are of HPLC grade obtained from Merck India Ltd.

Instrumentation

The Shimadzu HPLC equipment (LC-20AD) with a binary pump and UV-visible detector was utilized, along with an ELITE analytical balance. A C18 column with a particle size of 5 µm and dimensions of 250 x 4.6 mm was employed. Data was recorded using LC solution software and a rheodyne injector with a 20 µL loop.

Chromatographic Conditions

A 250 x 4.6 mm i.d., 5-µm particle Enable C18 G column was used for the chromatographic analysis. For separation, a mobile phase consisting of acetonitrile and water in an 80:20 v/v ratio was used, with a flow rate of 1.0 ml/min. The

eluents were detected at 247 nm with an injection volume of 20 µL. The HPLC system was operated at room temperature, which was 30 degrees Celsius.

Preparation of Stock and Standard Solutions

A 100 ml calibrated flask was filled with precisely weighed amounts of the pure drugs DAR and RIT, each containing 100 mg. 30 ml of acetonitrile was then added, and the flask was sonicated for 15 minutes. Acetonitrile is added until the volume is reached, creating a stock solution containing 1000 µg/ml of each DAR and RIT. To create a mixed working standard solution of DAR and RIT with 100 µg/ml each, 10 ml of each of the previously generated standard stock solutions of the two medications were pipetted and put into a 100 ml standard flask. The volume was then leveled with mobile phase.

Preparation of Sample Solution

Utilizing the present developed chromatographic conditions the assay of commercial tablets for the contents of DAR and RIT was established and it was found to be more accurate and reliable. For these twenty tablets (Label claim:800 mg DAR/ 100 mg RIT in each tablet) were weighed to compute the mean weight and comminuted to powdered form. From the comminuted tablet powder a weight equivalent to 10 mg DAR with relevant quantities of RIT was taken in to a 10 ml volumetric flask, added little quantity of acetonitrile; sonicated for 15 min and filtered through 0.45 µ Millipore filter. The volume of the clear solution was made to 10 ml with diluents (acetonitrile). From this 1 ml of solution was taken in 10 ml volumetric flask and volume was made up to 10 ml with mobile phase, and final solution (100 µg DAR, 12.5 µg RIT/ml) was analyzed by HPLC system.

Method Validation

As the guidelines framed by ICH the method validation was done for the parameters system suitability test, stability, and the validation parameters involving specificity, linearity, accuracy, precision and robustness.

RESULTS AND DISCUSSION

Optimization of Chromatographic Condition

According to UV spectrum analysis, DAR and RIT have good absorption at 247 nm. Consequently, the analytical wavelength for detection was set at 247 nm. A number of mobile phase compositions utilizing methanol, acetonirile, and water were tested in order to optimize the RP-HPLC process. A satisfactory separation was obtained with mobile phase composition of acteonitrile and water in 80:20 ratio. This particular composition showed good peak symmetry, resolution, tailing factor and theoretical plates better than the other compositions during our trails. Using UV detector, both sample solutions were observed to have their peak absrorbance at 247 nm when analysed simultaneously. The retention times of Darunavir ethanolate and Ritonavir were found to be 2.939 min and 3.537 min respectively. A chromatogram of optimized mixture is shown in [fig. 4] below

Method Validation System Suitability Test

Once the optimum conditions for chromatographic conditions were established for the developed method, system suitability parameters were estimated and compared with respect to acceptable limits. System suitability parameters of the method were presented in Table 1. The system suitability parameters were found to be within in the acceptance limit ranges and the considered appropriate for the analysis.

Stability of sample solution

The analysis was performed on the sample solution at 0, 12, 24, and 48 hours in order to examine its stability. There were no noticeable alterations to the developed approach. Additionally, results were found to be within acceptable limits (RSD <2), as shown in Table 2.

Linearity

The calibration curve for DAR and RIT was plotted in the concentration ranges of 10–50 µg/ml and 25–125 µg/ml, respectively. The regression equation for DAR was determined to be 6081.8 x + 83451 with a correlation coefficient of 0.9984 based on the calibration curve. With a correlation value of 0.9991, the regression equation for RIT was determined to be 15170 x – 6599.4. Table 3 displayed the linearity results for RIT and DAR. Figure 4 displayed the DAR and RIT linearity curves. From the linear regression data of the calibration curves of both drugs indicated a good linear response in the given the concentration range. The linearity curve can be applicable for quantification of DAR and RITin pharmaceutical formulation.

Sensitivity

The limits of detection (LOD) and quantitation (LOQ) values for both medications, which are shown in Table 3, were used to evaluate the sensitivity of the devised approach. The method's sensitivity is indicated by the low quantification and detection limits.

Precision

Three distinct concentrations were used for the intraday and interday precision studies (20, 30, and 40 µg/ml for RIT and 50, 75, and 100 µg/ml for DAR), and the percentage RSD was computed. Table 4 indicates that the approach had acceptable precision because the percentage RSD for both intraday and interday precision was less than 2%.

Accuracy

Recovery studies using the usual addition method were used to examine the method's accuracy. The preanalyzed sample solution was mixed with standard drug concentration at concentration levels of 80, 100, and 120 percent of the sample concentration. Three separate analyses were performed for each concentration. Table 5 displays the recovery study results, which ranged from 98 to 102% for both DAR and RIT.

Robustness

To investigate how the response is affected by the intentional modifications, a robustness analysis was conducted using minor adjustments to the technique parameters. The effects of variations in the analytical wavelength (± 2 nm), the organic makeup of the mobile phase (± 5% v/v), and the flow velocity (± 0.2 ml/min) were examined. Analyte recovery results were used to evaluate the results. The robustness of the procedure is demonstrated by the recovery data, which reveal that changes in flow rate, mobile phase composition, and analytical wavelength have no discernible effects on the analyte response. Table 6 displays the outcomes.

Sample Analysis

The devised method was applied in the examination of the tablet dosage form that contained a combination of DAR and RIT. The label stated for DAR and RIT was found to be in good accord with the mean percentage of satisfactory findings. The suggested approach might be used for the quantification of DAR and RIT in marketed tablets, according to the mean percentage found and the RSD values (Table 7).

CONCLUSION

In order to determine DAR and RIT simultaneously in bulk and in pharmaceutical formulation, an analytical method based on RP-HPLC has been devised. This method has been found to be straightforward, accurate, and selective. It can be used in routine labs and the pharmaceutical sector for process control of designed products and bulk drugs.

ACKNOWEDGEMENT

The authors are grateful to Dr. Y Srinivasa Rao, Principal, Vignan Institute of Pharmaceutical Technology for providing necessary facilities to carry out the above research work.

ABSTRACT

In this Paper we compute FuzzyEigen values and Eigen vectors of Fuzzy domination for some Fuzzy graphs. Also we have derived some properties and examples are given to verify the properties. The study of domination in Fuzzy graphs using Eigen values and Eigen vectors is motivated by the need to apply Fuzzy graph theory to real world problems in network analysis, decision making systems and social network analysis.

Keywords: Fuzzy dominating set, Fuzzy dominant matrix, Characteristic equation, Fuzzy Eigen value, Fuzzy Eigen vector.

INTRODUCTION

Fuzzy graphs serve as an effective instrument for modelling intricate systems characterized by uncertain relationships. In Fuzzy graph theory, Fuzzy domination is a key concept that helps us understand the structure and properties of these graphs. Fuzzy domination refers to the ability of a subset of vertices to dominate or control the entire graph. In 1965, Zadeh [12] introduced the notion of fuzzy sets. The notion of Fuzzy graph was introduced by Rosenfeld in 1975 while the concept of domination for Fuzzy graph was introduced by Somasundaram and Somasundaram [1] .Buckley [10] explored Fuzzy eigen values with positive elements. Theodoroua *et al*. [16] investigated the fuzzy eigenvalues associated with triangular fuzzy numbers. Indirani and Saranya[11]they

addressed some properties of eigen values.M.Clement Joe Anand and M.Edal Anand [2] discussed some proprties of eigen values and eigen vectors for fuzzy matrix. P. Priya *et al*. discussed fundamental concepts related to fuzzy matrices. A.Nagoorgani and V.T. Chandrasekaran [13]discussed some properties of dominating set and found domination number. Benjier H. Arriola [4] discussed some domination of Fuzzy graphs. This paper consists of four sections. In first section, we give the introduction. Basic definitions of fuzzy graph, domination of fuzzy graph, Fuzzy dominant matrix, Fuzzy Eigen values and Eigen vectors were discussed in the second section. In the third section, we proved the properties of Fuzzy Eigen values and Eigen vectors of fuzzy domination for fuzzy graphs. Finally, we give the conclusion.

PRELIMINARIES

Definition[12]
A fuzzy set is characterized by a membership function Ω mapping the elements of a domain, space or universe of discourse V to the unit interval [0, 1].Let Ω be a fuzzy subset of V and ϕ is a fuzzy relation on Ω if ϕ(x,y) ≤ Ω (x)∧ Ω (y), for all x, y∈V ,where ∧ means 'inf'.

Definition[5]
A fuzzy graph $\mathcal{F}$ is an ordered pair F (Ω, ϕ) where Ω : V⟶[0,1] is a fuzzy subset of V and ϕ: V×V⟶[0,1] is a relation on V suchthat ϕ(x,y) ≤ Ω(x)∧Ω (y), for all x,y ∈V. We denote V and E as vertex set and edge set of F respectively.

Definition[4]
An edge (xy) of a fuzzy graph $\mathcal{F}$ is called an effective edge or strong edge if
(i)ϕ (x,y) = Ω(x)∧Ω(y), for all x, y ∈ V (ii) Ω(x)<Ω(y), for all x, y ∈ V.

Definition[13]
A subset $\mathfrak{D}$of V is said to be a dominating fuzzy set of a fuzzy graph if for every y∈ V- $\mathfrak{D}$, there exists x∈$\mathfrak{D}$ such that 'x dominates y'. A dominating fuzzy set is referred to as a minimal dominating fuzzy set if no proper subset of the dominating fuzzy set qualifies as a dominating fuzzy set.

Definition[13]
The fuzzy domination number of the fuzzy graph $\mathcal{F}$, denoted as $\gamma_{fd}(\mathcal{F})$ refers to the dominating fuzzy set that possesses the minimum fuzzy cardinality. The fuzzy domination number of the fuzzy graph $\mathcal{F}$, denoted as $\gamma_{fd}(\mathcal{F})$, refers to the dominating fuzzy set that possesses the minimum fuzzy cardinality.

Definition[3]
Let F(V,Ω,ϕ) be a fuzzy graph. The fuzzy dominant matrix of a fuzzy dominating set of order n is denoted by$\mathfrak{D}_{ij}^{(f)}$and is defined by $\mathfrak{D}_{ij}^{(f)}$= {(Ω(v_i) if i =j ; ϕ (v_i,v_j) if i≠j)} .

Note
- Fuzzy dominant matrix of dominating fuzzy set is a square matrix of order n.
- Always Fuzzy dominant matrix is symmetric.

Definition
Let$\mathfrak{D}_{ij}^{(f)}$ be a square dominating matrix of fuzzy dominating set of fuzzy graph $\mathcal{F}$ of order n. Let λ_{fd} be any scalar in [0, 1]. The equation $\left|\mathfrak{D}_{ij}^{(f)} - \lambda_{fd} I\right|$ = 0 is called the characteristic equation of the fuzzy dominant matrix of fuzzy dominating set .

Definition

The values of λ_{fd} obtained from the characteristic equation $\left|\mathfrak{D}_{ij}^{(f)} - \lambda_{fd} I\right| = 0$ are called fuzzy Eigen values or characteristic root of $\mathfrak{D}_{ij}^{(f)}$.

Definition

Any non-zero vector D is said to be a fuzzy characteristic vector or fuzzy Eigen vector of a dominant matrix $\mathfrak{D}_{ij}^{(f)}$if there exists a number λ_{fd}such that $\mathfrak{D}_{ij}^{(f)}$D= λ_{fd}D where

$\mathfrak{D}_{ij}^{(f)}$=[a_{ij}] is a square matrix and D = $\begin{pmatrix} d_1 \\ d_2 \\ \vdots \\ d_n \end{pmatrix}$ is a column vector.

Definition[2]

A square fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$= $[a_{ij}]$of order n is termed **symmetric** if$a_{ij} = a_{ji}$for all i and j.

Definition

A square fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$= $[a_{ij}]$of order n is called **scalar matrix** if all the diagonal elements are identical.

Definition[2]

Two Eigen vectors $D_1$and $D_2$of fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$= $[a_{ij}]$ are called orthogonal vectors if ${D_1}^T D_2 = 0$.

Note

Let $\mathfrak{D}_{ij}^{(f)}$= $[a_{ij}]$ be a square fuzzy dominant matrix of order n.

- If $\left|\mathfrak{D}_{ij}^{(f)}\right| = 0$, then the eigenvectors of the fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$are linearly dependent.
- If $\left|\mathfrak{D}_{ij}^{(f)}\right| \neq 0$ then the eigen vectors of the fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$ are Linearly independent.

Working rule for computing fuzzy Eigen values and Eigen Vectors

- Initially find the dominating set for the given fuzzy graph.
- Construct the fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$
- Formulate the characteristic equation $\left|\mathfrak{D}_{ij}^{(f)} - \lambda_{fd} I\right| = 0$for the square fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$.
- By solving the characteristic equation, find the fuzzy Eigen values of fuzzy dominant matrix.
- Find fuzzy Eigen vectors corresponding to each fuzzy Eigen values from the equation

$(\mathfrak{D}_{ij}^{(f)} - \lambda_{fd} I)$D= 0.

Properties of Fuzzy Eigen values and Eigen vectors

Property(3.1)

(a)The aggregate of the fuzzy eigenvalues of a fuzzy dominant matrix is equivalent to the summation of its principal diagonal elements. (b)Furthermore, the product of the fuzzy eigenvalues is equivalent to the determinant of the fuzzy dominant matrix.

Proof

(a)Let $\mathfrak{D}_{ij}^{(f)}$ be a fuzzy dominant matrix of order n. Then the characteristic equation of $\mathfrak{D}_{ij}^{(f)}$ is $\left|\mathfrak{D}_{ij}^{(f)} - \lambda_{fd} I\right| = 0$.

that is ${\lambda_{fd}}^n - c_1{\lambda_{fd}}^{n-1} + c_2{\lambda_{fd}}^{n-2} + \cdots \ldots + (-1)^n c_n = 0 \quad ----\rightarrow (3.1)$

where c_1 = sum of the diagonal elements of $\mathfrak{D}_{ij}^{(f)}$.

c_2 = sum of the minors of main diagonal elements of $\mathfrak{D}_{ij}^{(f)}$.

$c_n =$ determinant of $\mathfrak{D}_{ij}^{(f)}$

Solving equation (3.1) , we get n roots, let them be λ_{fd1} ,λ_{fd2},λ_{fd3} …… λ_{fdn}.

These roots are referred to as fuzzy Eigenvalues of $\mathfrak{D}_{ij}^{(f)}$

We know that, any polynomial equation of order n is of the form is

$\lambda_{fd}{}^{n} - (sum\ of\ roots)\lambda_{fd}{}^{n-1} + \cdots (-1)^{n}(product\ of\ roots) = 0$ ------⟶(3.2)

Comparing equations (3.1) and (3.2) we get c_1 = sum of the roots

ie) sum of main diagonal elements of $\mathfrak{D}_{ij}^{(f)} = \lambda_{fd1} + \lambda_{fd2} + \lambda_{fd3} \ldots\ldots + \lambda_{fdn}$.

(b) By analysing equations (3.1) and (3.2), we deduce that $c_n$is equal to the product of the roots.

Property(3.2)

If λ_{fd} is a fuzzy Eigen value of the fuzzy dominant matrix$\mathfrak{D}_{ij}^{(f)}$ then λ_{fd} is also a fuzzy Eigen value of the transpose of fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$.

Proof

Let λ_{fd} be a fuzzy Eigen value of the fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$.Then the characteristic equation of $\mathfrak{D}_{ij}^{(f)}$ is $\left|\mathfrak{D}_{ij}^{(f)} - \lambda_{fd}I\right| = 0$ and the characteristic equation of transpose of $\mathfrak{D}_{ij}^{(f)}$ is $\left|(\mathfrak{D}_{ij}^{(f)})^{\mathrm{T}} - \lambda_{fd}I\right| = 0.$

Since fuzzy dominant matrix is symmetric, we have $\left|\mathfrak{D}_{ij}^{(f)} - \lambda_{fd}I\right| = \left|(\mathfrak{D}_{ij}^{(f)})^{\mathrm{T}} - \lambda_{fd}I\right|$

That is, the characteristic equations are same for both $\mathfrak{D}_{ij}^{(f)}$and $(\mathfrak{D}_{ij}^{(f)})^{\mathrm{T}}$.

Hence λ_{fd} is also fuzzy Eigen value of $(\mathfrak{D}_{ij}^{(f)})^{\mathrm{T}}$.

Property(3.3)

If λ_{fd} is a fuzzy Eigen value of the fuzzy dominant matrix$\mathfrak{D}_{ij}^{(f)}$.Then $\frac{1}{\lambda_{fd}}, \lambda_{fd} \neq 0$ is approximately equal to the fuzzy Eigen value $(\mathfrak{D}_{ij}^{(f)})^{-1}$.

Proof

Letλ_{fd} be a fuzzy Eigen value of the fuzzy dominant matrix$\mathfrak{D}_{ij}^{(f)}$.

Then$\mathfrak{D}_{ij}^{(f)}D = \lambda_{fd}D$------>(3.3)

Pre multiplying both sides of equation (3.3) by $(\mathfrak{D}_{ij}^{(f)})^{-1}$

$(\mathfrak{D}_{ij}^{(f)})^{-1}\mathfrak{D}_{ij}^{(f)}D = (\mathfrak{D}_{ij}^{(f)})^{-1}\lambda_{fd}D$

$\mathrm{D} = \lambda_{fd}(\mathfrak{D}_{ij}^{(f)})^{-1}D$

$(\mathfrak{D}_{ij}^{(f)})^{-1}D = \frac{1}{\lambda_{fd}}\mathrm{D}$

Hence $\frac{1}{\lambda_{fd}}$ is a fuzzy Eigen value $(\mathfrak{D}_{ij}^{(f)})^{-1}$.

Property(3.4)

If λ_{fd} is a fuzzy Eigen value of the fuzzy dominant matrix$\mathfrak{D}_{ij}^{(f)}$.Then $(\lambda_{fd})^{k}$ is approximately equal to the fuzzy Eigen value of $(\mathfrak{D}_{ij}^{(f)})^{k}$.

Proof

Letλ_{fd} be a fuzzy Eigen value of the fuzzy dominant matrix$\mathfrak{D}_{ij}^{(f)}$.

Then $\mathfrak{D}_{ij}^{(f)}D = \lambda_{fd}D$ ------>(3.3)

Pre multiplying both sides of equation (3.3) by $\mathfrak{D}_{ij}^{(f)}$.

$\mathfrak{D}_{ij}^{(f)}.\ \mathfrak{D}_{ij}^{(f)}D = \mathfrak{D}_{ij}^{(f)}.\lambda_{fd}D$

$(\mathfrak{D}_{ij}^{(f)})^2D = \lambda_{fd}(\mathfrak{D}_{ij}^{(f)}D) = \lambda_{fd}(\lambda_{fd}D)$

$(\mathfrak{D}_{ij}^{(f)})^2D = (\lambda_{fd})^2D$

Similarly *we have proved* $(\mathfrak{D}_{ij}^{(f)})^3D = (\lambda_{fd})^3D$, In general $(\mathfrak{D}_{ij}^{(f)})^kD = (\lambda_{fd})^kD$.

Remark

For verifying, the properties of fuzzy Eigen values, we get the values are approximate only but if using the values which is correct to one decimal places the Eigen values are in proper manner. For, In example (3.1), The fuzzy Eigen values of $\mathfrak{D}_{ij}^{(f)}$ are 0.462 and 0.238 respectively. But the fuzzy Eigen values of $(\mathfrak{D}_{ij}^{(f)})^2$ are 0.215 and 0.055 respectively. Here the errors are 0.002 and 0.002 respectively

Property(3.5)

If λ_{fd} is a fuzzy Eigen value of the fuzzy dominant matrix$\mathfrak{D}_{ij}^{(f)}$.Then $\lambda_{fd} \pm k$ is a fuzzy Eigen value of $\mathfrak{D}_{ij}^{(f)} \pm k$,where k is any positive integer

Proof

Letλ_{fd} be a fuzzy Eigen value of the fuzzy dominant matrix$\mathfrak{D}_{ij}^{(f)}$.

Then $\mathfrak{D}_{ij}^{(f)}D = \lambda_{fd}D$------>(3.3)

Adding kID both sides of equation (3.3) by $\mathfrak{D}_{ij}^{(f)}$.

$\mathfrak{D}_{ij}^{(f)}D + \text{kID} = \lambda_{fd}D$ +kID

$(\mathfrak{D}_{ij}^{(f)} + \text{kI})\text{D} = (\lambda_{fd}$ +kI)D. Similarly $(\mathfrak{D}_{ij}^{(f)} - \text{kI})\text{D} = (\lambda_{fd}$-kI)D

In general , $(\mathfrak{D}_{ij}^{(f)} \pm \text{kI})\text{D} = (\lambda_{fd} \pm$kI)D.

$\lambda_{fd} \pm k$ is a fuzzy Eigen value of $\mathfrak{D}_{ij}^{(f)} \pm k$,where k is any positive integer

Property(3.6)

If λ_{fd} is a fuzzy Eigen value of the fuzzy dominant matrix$\mathfrak{D}_{ij}^{(f)}$.Then $k\lambda_{fd}$ is a fuzzy Eigen value of $k\mathfrak{D}_{ij}^{(f)}$,where k is any scalar.

Proof

Letλ_{fd} be a fuzzy Eigen value of the fuzzy dominant matrix$\mathfrak{D}_{ij}^{(f)}$.

Then $\mathfrak{D}_{ij}^{(f)}D = \lambda_{fd}D$ ------>(3.3)

multiplying both sides of equation (3.3) by the scalar k, then $k\ \mathfrak{D}_{ij}^{(f)}D = k\ \lambda_{fd}D$ .Hence $k\lambda_{fd}$ is a fuzzy Eigen value of $k\mathfrak{D}_{ij}^{(f)}$,where k is any scalar.

Property(3.7)

The fuzzy eigenvalues associated with the diagonal fuzzy dominant matrix of order n are equivalent to the diagonal elements.

Proof

Let $\mathfrak{D}_{ij}^{(f)} = \begin{pmatrix} a_{11} & 0 & \cdots & 0 \\ \vdots & & \ddots & \vdots \\ 0 & 0 & \cdots & a_{nn} \end{pmatrix}$ be a diagonal fuzzy dominant matrix of order n

The characteristic equation for the transpose of $\mathfrak{D}_{ij}^{(f)}$ is given by $\left|(\mathfrak{D}_{ij}^{(f)})^{\mathrm{T}} - \lambda_{fd}I\right| = 0$.

That is $(a_{11}-\lambda_{fd})(a_{22}-\lambda_{fd})(a_{33}-\lambda_{fd})\ldots\ldots(a_{nn}-\lambda_{fd}) = 0$.
$\lambda_{fd} = a_{11}, a_{22}, \ldots\ldots a_{nn}$.
Hence, the fuzzy Eigen values associated with the diagonal fuzzy dominant matrix of order n are equivalent to the diagonal elements.

Proposition (3.1)
If a fuzzy dominant symmetric matrix of order n has equal fuzzy Eigen values, then the dominant matrix is a fuzzy scalar matrix.

Example (3.1)(Fig.1)
Here Fuzzy dominating set is $\{v_2, v_5\}$, Fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)} = \begin{pmatrix} 0.4 & 0 \\ 0 & 0.4 \end{pmatrix}$,
fuzzy Eigen values are 0.4 and 0.4.In particular $\mathfrak{D}_{ij}^{(f)}$ is a fuzzy scalar matrix.

Example (3.2) (Fig.2)
Here Fuzzy dominating set is $\{v_1, v_{3,} v_5\}$, Fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)} = \begin{pmatrix} 0.3 & 0 & 0 \\ 0 & 0.3 & 0 \\ 0 & 0 & 0.3 \end{pmatrix}$,
The fuzzy eigenvalues are 0.3(thrice). Specifically, $\mathfrak{D}_{ij}^{(f)}$represents a fuzzy scalar matrix.

Property(3.8)
If D is a fuzzy eigenvector of a fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$ associated with the fuzzy eigenvalue $\lambda_{fd}D$, then kD is also a fuzzy eigenvector of $\mathfrak{D}_{ij}^{(f)}$ corresponding to the same fuzzy Eigen value $\lambda_{fd}D$, where k is a non -zero scalar.

Proof
Let D represent a fuzzy Eigen vector of a fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$that is associated with the fuzzy Eigen value $\lambda_{fd,}$. Then $\mathfrak{D}_{ij}^{(f)}$D= $\lambda_{fd}D$, D≠0.
If k is any non -zero scalar then , $kD \neq 0$.
Also $\mathfrak{D}_{ij}^{(f)}(kD) = k\left(\mathfrak{D}_{ij}^{(f)}D\right) = k(\lambda_{fd}D) = \lambda_{fd}(kD)$, Hence proved.

Property(3.9)
If D is a fuzzy Eigen vector of a fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$ then D cannot corresponding to more than one fuzzy Eigen value of $\mathfrak{D}_{ij}^{(f)}$.

Proof
Let D be a fuzzy Eigen vector of a fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$ corresponding to two fuzzy Eigen values λ_{fd1} $and\, \lambda_{fd2}$, we have $\mathfrak{D}_{ij}^{(f)}D = \lambda_{fd1}D$and $\mathfrak{D}_{ij}^{(f)}D = \lambda_{fd2}D$, which implies $\lambda_{fd1}D = \lambda_{fd2}D$, $(\lambda_{fd1} - \lambda_{fd2})\, D = 0$,$\lambda_{fd1} = \lambda_{fd2}$ (since $D \neq 0$). Hence, D cannot corresponding to more than one fuzzy Eigen value of $\mathfrak{D}_{ij}^{(f)}$.

Property(3.10)
The fuzzy Eigen vector corresponding to distinct fuzzy Eigen value of fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$ are linearly independent.

Proof
Let $D_1, D_2 \ldots . D_m$represent the fuzzy eigen vectors associated with the distinct fuzzy Eigen values λ_{fd1} , $\lambda_{fd3} \ldots \ldots . \lambda_{fdm}$. The equation $\mathfrak{D}_{ij}^{(f)}D_i = \lambda_{fdi}D_i$ holds for i= 1,2,…….m.

Let the fuzzy Eigen vectors $D_1, D_2 \ldots . D_m$ be linearly dependent. Select ιin such a way that the fuzzy Eigen vectors $D_1, D_2 \ldots . D_\iota$ are linearly independent while $D_1, D_2 \ldots . D_\iota, D_{\iota+1}$ are linearly dependent, given that $1 \leq \iota \leq m$. Then $k_1 D_1 + k_2 D_2 \ldots . + k_\iota D_\iota + k_{\iota+1} D_{\iota+1} = 0 \ldots\ldots\ldots$>(3.4)Where $k_1, k_2 \ldots \ldots k_{\iota+1}$ are non-zero scalars.

$\mathfrak{D}_{ij}^{(f)}(k_1 D_1 + k_2 D_2 \ldots . + k_\iota D_\iota + k_{\iota+1} D_{\iota+1}) = 0$

$k_1(\mathfrak{D}_{ij}^{(f)} D_1) + k_2(\mathfrak{D}_{ij}^{(f)} D_2) + \ldots\ldots\ldots + k_{\iota+1}(\mathfrak{D}_{ij}^{(f)} D_{\iota+1}) = 0$

$k_1(\lambda_{fd1} D_1) + k_2(\lambda_{fd2} D_2) + \ldots\ldots\ldots + k_{\iota+1}(\lambda_{fd(\iota+1)} D_{\iota+1}) = 0 \ldots\ldots\ldots$>(3.5)

From equations (3.4) and (3.5) we get,

$k_1(\lambda_{fd1} - \lambda_{fd(\iota+1)}) D_1 + k_2(\lambda_{fd2} - \lambda_{fd(\iota+1)}) D_2 + \ldots\ldots\ldots + k_\iota(\lambda_{fd\iota} - \lambda_{fd(\iota+1)}) D_\iota = 0$

Since $D_1, D_2 \ldots . D_m$ *are* linearly independent,

$k_1(\lambda_{fd1} - \lambda_{fd(\iota+1)}) = 0, k_2(\lambda_{fd2} - \lambda_{fd(\iota+1)}) = 0 \ldots \ldots . k_\iota(\lambda_{fd\iota} - \lambda_{fd(\iota+1)}) = 0$

But λ_{fd1} , $\lambda_{fd2}, \lambda_{fd3} \ldots \ldots . \lambda_{fd(\iota+1)}$ are distinct, therefore $k_1 = k_2 = \cdots . . = 0$,substitute these values in (3.4) we get $k_{\iota+1} D_{\iota+1} = 0$ implies $k_{\iota+1} = 0$ (since $D_{\iota+1} \neq 0$)Therefore we have

$k_1 = k_2 = \cdots . . k_{\iota+1} = 0$ which contradicts our assumption that $k_1, k_2, \ldots . . k_{\iota+1}$ are not all zero.

Property(3.11)

The fuzzy eigen vector of a fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$ is not unique.

Proof

Let λ_{fd} berepresent the fuzzy eigen value of *the* fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$,then the associated fuzzy eigen vector D such that $\mathfrak{D}_{ij}^{(f)} D = \lambda_{fd} D$, $D \neq 0$, K($\mathfrak{D}_{ij}^{(f)} D$) is equal to k($\lambda_{fd} D$),$\mathfrak{D}_{ij}^{(f)}$(K$D$) = λ_{fd} (kD)

Hence, fuzzy Eigen vector is not unique.

Property(3.12)

If A_{fd} and B_{fd} are n×n fuzzy dominant matrices, and B_{fd} is a non-singular fuzzy dominant matrix, then A_{fd} and ${B_{fd}}^{-1} A_{fd} B_{fd}$possess identical fuzzy eigenvalues.

Example(3.3)

$A_{fd} = \begin{pmatrix} 0.5 & 0.3 \\ 0.3 & 0.4 \end{pmatrix}$, $B_{fd} = \begin{pmatrix} 0.4 & 0.7 \\ 0.7 & 0.6 \end{pmatrix}$, In this example fuzzy eigenvalues of A_{fd} and ${B_{fd}}^{-1} A_{fd} B_{fd}$ are 0.754 and 0.146.

RESULTS

- The fuzzy Eigen vectors corresponding to distinct fuzzy Eigen values of a fuzzy dominant symmetric matrix are not orthogonal.
- The fuzzy Eigen values of a diagonal fuzzy dominant matrix of order n are the diagonal elements but in the fuzzy matrix, the fuzzy Eigen values of a triangular matrix of order n are the diagonal elements.

Properties of fuzzy Eigen values and Eigen vectors verified by the following examples

Example(3.4)(Fig. 3)

In this example ,we examine a Regular fuzzy graph ,Here ,The fuzzy dominating set is $\{v_1, v_4\}$, The fuzzy domination number $\gamma_{fd}(\mathcal{F})$ is 0.7. The fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$of order 2 is $\begin{pmatrix}0.3 & 0.1\\ 0.1 & 0.4\end{pmatrix}$. The fuzzy eigenvalues are 0.462 and 0.238 while the fuzzy eigenvectors are $D_1 = \begin{pmatrix}0.1\\ 0.162\end{pmatrix}$, $D_2 = \begin{pmatrix}0.1\\ -0.062\end{pmatrix}$.

Example(3.5)(Fig.4)

In this example , The fuzzy dominating set is $\{v_2, v_5\}$, Fuzzy domination number $\gamma_{fd}(\mathcal{F}) = 0.9$,

Fuzzy diagonal dominant matrix $\mathfrak{D}_{ij}^{(f)}$of order 2 is $\begin{pmatrix}0.4 & 0\\ 0 & 0.5\end{pmatrix}$,fuzzy eigenvalues are 0.4 and 0.5,fuzzy eigenvectors are $D_1 = \begin{pmatrix}0\\ 0.1\end{pmatrix}$, $D_2 = \begin{pmatrix}0\\ 0.1\end{pmatrix}$

Example(3.6)(Fig.5)

In this example ,The fuzzy dominating set is $\{v_2, v_4\}$, Fuzzy domination number $\gamma_{fd}(\mathcal{F}) = 1$,Fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$of order 2 is $\begin{pmatrix}0.4 & 0.3\\ 0.3 & 0.6\end{pmatrix}$,fuzzy eigenvalues are 0.185 and 0.815,fuzzy eigenvectors are $D_1 = \begin{pmatrix}0.3\\ -0.215\end{pmatrix}$, $D_2 = \begin{pmatrix}0.3\\ 0.415\end{pmatrix}$.

Example(3.7) (Fig.6)

In this context, the fuzzy dominating set is $\{v_2, v_4, v_7\}$ and the fuzzy domination number $\gamma_{fd}(\mathcal{F})$ is equal to 1.Fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$of order 3 is $\begin{pmatrix}0.3 & 0 & 0\\ 0 & 0.4 & 0.2\\ 0 & 0.2 & 0.3\end{pmatrix}$. The

fuzzy eigenvalues are 0.15,0.29 and 0.56. The associated fuzzy eigenvectors are $D_1 = \begin{pmatrix}0\\ -0.03\\ 0.038\end{pmatrix}$,

$D_2 = \begin{pmatrix}-0.039\\ 0\\ 0\end{pmatrix}$,$D_3 = \begin{pmatrix}0\\ 0.052\\ 0.042\end{pmatrix}$

Example(3.8) (Fig.7)

Here, The fuzzy dominating set is $\{v_2, v_4, v_7\}$, Fuzzy domination number $\gamma_{fd}(\mathcal{F}) = 0.8$,

The fuzzy diagonal dominant matrix $\mathfrak{D}_{ij}^{(f)}$of order 3 is represented as $\begin{pmatrix}0.3 & 0 & 0\\ 0 & 0.1 & 0\\ 0 & 0 & 0.4\end{pmatrix}$. The fuzzy eigenvalues are 0.1,0.3 and 0.4 while the fuzzy eigenvectors are defined as $D_1 = \begin{pmatrix}0\\ 0.06\\ 0\end{pmatrix}$, $D_2 = \begin{pmatrix}0.2\\ 0\\ 0\end{pmatrix}$,$D_3 = \begin{pmatrix}0\\ 0\\ 0.03\end{pmatrix}$

OBSERVATIONS

- All fuzzy Eigen values of the fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$ are are located within the interval [0,1] ie) $\lambda_{fd}(\mathfrak{D}_{ij}^{(f)}) \in$ [0,1].
- Fuzzy domination number of the fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$is greater than theFuzzy Eigen values of the fuzzy dominant matrix $\mathfrak{D}_{ij}^{(f)}$.

CONCLUSIONS

In this paper, we derived some properties of fuzzy Eigen value and Eigen vector of the fuzzy dominant matrix in fuzzy domination of a graph. Also explained some examples which are satisfied the properties of fuzzy Eigen value and Eigen vector. Fuzzy Eigen values and Eigen vectors can provide insight into the spectral properties of fuzzy graphs, which can be related to fuzzy domination.

ABSTRACT

In this paper, we introduce a new domination parameter called the *accurate semitotal domination number*. A set D of vertices in a graph G with no isolated vertices is an accurate semitotal dominating set of G, if D is a semitotal dominating set of G and no $|D|$- element subset of $V \setminus D$ is a semitotal dominating set of G. The minimum cardinality of an accurate semitotal dominating set of G is called the *accurate semitotal domination number* and is denoted by $\gamma_{at2}(G)$.Fundamental properties of this parameter are explored. Exact values are determined for various standard graphs. This study contributes a new direction to the ongoing development of domination theory.

Keywords: graphs, accurate semitotal dominating set, accurate semitotal domination number

INTRODUCTION

The graphs considered here are simple, finite, nontrivial, undirected and without isolated vertices. The graph $G = (V, E)$ considered here have $n = |V|$ vertices and $m = |E|$ edges. A set D of vertices in a graph G is a dominating set if every vertex not in D is adjacent to at least one vertex in D. The domination number $\gamma(G)$ of G is the order of a smallest dominating set in G.Any dominating set with $\gamma(G)$ vertices is called a $\gamma(G)$ – set of G.The concept of accurate domination in graphs was introduced by V.R. Kulli and M.B. Kattimani [1]. A dominating set D of a graph G is an accurate dominating set, if $V \setminus D$has no dominating set of cardinality $|D|$. The accurate domination number $\gamma_a(G)$ of G

is the minimum cardinality of an accurate dominating set. Any accurate dominating set with $\gamma_a(G)$ vertices is called a $\gamma_a(G)$ – set of G.The concept of semitotal domination was introduced by Wayne Goddard, Michael A. Henning and Charles A. McPillan [2]. A set D of vertices in a graph G with no isolated vertices to be a semitotal dominating set of G if it is a dominating set of G and every vertex in D is within distance 2 of another vertex of D. The semitotal domination number, denoted by $\gamma_{t2}(G)$, is the minimum cardinality of a semitotal dominating set. Any semitotal dominating set with $\gamma_{t2}(G)$ vertices is called a $\gamma_{t2}(G)$ – set of G. Motivated by these two domination parameters accurate semitotal domination number was devised. In this paper we determine the accurate semitotal domination number of some standard graphs and the fundamental properties of this parameter are also discussed.

Theorem [2]: If G has n vertices and maximum degree Δ, then $\gamma_{t2}(G) \geq \frac{2n}{2\Delta+1}$.

METHODS

Definition: A set D of vertices in a graph G with no isolated vertices is an*accurate semitotal dominating set* of G, if D is a semitotal dominating set of G and no $|D|$- element subset of $V \setminus D$ is a semitotal dominating set of G. The minimum cardinality of an accurate semitotal dominating set of G is called the *accurate semitotal domination number* and is denoted by $\gamma_{at2}(G)$. Any accurate semitotal dominating set with $\gamma_{at2}(G)$ vertices is called a $\gamma_{at2}(G)$ – set of G.
Example: For the graph G_1 in Figure 1, $D = \{v_4, v_5\}$ forms a $\gamma_{at2}(G_1)$ – set. Hence $\gamma_{at2}(G_1) = 2$.

RESULTS AND DISCUSSION

Observation: If an accurate semitotal dominating set exists for the graph G, then $\gamma_{at2}(G) \geq 2$.
Observation: Every accurate semitotal dominating set is an accurate dominating set, but not conversely.
Observation: Every accurate semitotal dominating set is a semitotal dominating set, but not conversely.
Observation: Let G be a connected graph that has a $\gamma_{at2}(G)$ – set but the complement of$G$ need not contain a $\gamma_{at2}(\bar{G})$ – set.
Exact values for some standard graphs:

1) For any path P_n of order $n \geq 2$, $\gamma_{at2}(P_n) = \begin{cases} 2, & n = 2 \\ \left\lceil \frac{2n}{5} \right\rceil, & n \geq 3 \end{cases}$

2) For any cycle C_n of order $n \geq 3$, $\gamma_{at2}(C_n) = \begin{cases} n-1, & n = 3,4 \\ \left\lceil \frac{2n}{5} \right\rceil, & n \equiv 4 \ (mod\ 5) \\ \left\lceil \frac{2n}{5} \right\rceil + 1, & otherwise \end{cases}$

3) For any complete graph K_n of order $n \geq 3$, $\gamma_{at2}(K_n) = \left\lfloor \frac{n}{2} \right\rfloor + 1$

4) For any complete bipartite graph $K_{m,n}$, where $m, n \geq 1$,

$$\gamma_{at2}(K_{m,n}) = \begin{cases} m+1, & if\ m = n \\ 2, & if\ m = 1\ and\ n > 1 \\ m, & if\ n > m \geq 2 \end{cases}$$

Proof:
1)Let $G = P_n$ be a path. Let $V = \{v_i : 1 \leq i \leq n\}$ be the vertex set of G. For n = 2,3,4, the result is obvious. Now, for $n \geq 5$, we consider the following cases:
Case (i): For $n \equiv 0\ (mod\ 5)$,

The set $D = \left\{v_{5i-3}, v_{5i-1} : 1 \leq i \leq \frac{n}{5}\right\}$, forms a $\gamma_{at2}(G)$ – set.

Case (ii): For $n \equiv 1\ (mod\ 5)$,

The set $D = \left\{v_{5i-3}, v_{5i-1} : 1 \leq i \leq \frac{n-1}{5}\right\} \cup \{v_{n-1}\}$, forms a $\gamma_{at2}(G)$ – set.

Case (iii): For $n \equiv 2\ (mod\ 5)$,

The set $D = \left\{v_{5i-3}, v_{5i-1}: 1 \leq i \leq \frac{n-2}{5}\right\} \cup \{v_{n-1}\}$, forms a $\gamma_{at2}(G)$ – set.

Case (iv): For $n \equiv 3\ (mod\ 5)$,

The set $D = \left\{v_{5i-3}, v_{5i-1}: 1 \leq i \leq \frac{n-3}{5}\right\} \cup \{v_{n-2}, v_{n-1}\}$, forms a $\gamma_{at2}(G)$ – set.

Case (v): For $n \equiv 4\ (mod\ 5)$,

The set $D = \left\{v_{5i-3}, v_{5i-1}: 1 \leq i \leq \frac{n-4}{5}\right\} \cup \{v_{n-2}, v_{n-1}\}$, forms a $\gamma_{at2}(G)$ – set.

2)Let $G = C_n$ be a cycle. Let $V = \{v_i: 1 \leq i \leq n\}$ be the vertex set of G. For $n = 3,4$, the result is obvious. For $n \geq 5$, we consider the following cases:

Case (i): For $n \equiv 0\ (mod\ 5)$,

The set $D = \left\{v_{5i-3}, v_{5i-1}: 1 \leq i \leq \frac{n}{5}\right\} \cup \{v_{n-2}\}$, forms a $\gamma_{at2}(G)$ – set.

Case (ii): For $n \equiv 1\ (mod\ 5)$,

The set $D = \left\{v_{5i-3}, v_{5i-1}: 1 \leq i \leq \frac{n-1}{5}\right\} \cup \{v_{n-1}, v_n\}$, forms a $\gamma_{at2}(G)$ – set.

Case (iii): For $n \equiv 2\ (mod\ 5)$,

The set $D = \left\{v_{5i-3}, v_{5i-1}: 1 \leq i \leq \frac{n-2}{5}\right\} \cup \{v_{n-2}, v_{n-1}\}$, forms a $\gamma_{at2}(G)$ – set.

Case (iv): For $n \equiv 3\ (mod\ 5)$,

The set $D = \left\{v_{5i-3}, v_{5i-1}: 1 \leq i \leq \frac{n-3}{5}\right\} \cup \{v_{n-3}, v_{n-2}, v_{n-1}\}$, forms a $\gamma_{at2}(G)$ – set.

Case (v): For $n \equiv 4\ (mod\ 5)$,

The set $D = \left\{v_{5i-3}, v_{5i-1}: 1 \leq i \leq \frac{n-4}{5}\right\} \cup \{v_{n-2}, v_{n-1}\}$, forms a $\gamma_{at2}(G)$ – set.

Let $G = K_n$ be a complete graph. Let $V = \{v_i: 1 \leq i \leq n\}$ be the vertex set of K_n. For $n \geq 3$, the set $D = \left\{v_j: 1 \leq j \leq \left\lfloor\frac{n}{2}\right\rfloor\right\} \cup \{v_k\}$,where $k \notin \left\{j: 1 \leq j \leq \left\lfloor\frac{n}{2}\right\rfloor\right\}$, forms a $\gamma_{at2}(G)$ – set.

Let $G = K_{m,n}$ be a complete bipartite graph. Let $V = \{u_i, v_j: 1 \leq i \leq m,\ 1 \leq j \leq n\}$ be the vertex set of G. For $m, n \geq 1$,we consider the following cases:

Case (i): Suppose $m = n$.

Then the set $D = \{u_i: 1 \leq i \leq m\} \cup \{v_j\}$, where $1 \leq j \leq n$, forms a $\gamma_{at2}(G)$ – set.

Case (ii): Suppose$m = 1$ and $n > 1$.

It represents the star graph $K_{1,n}$. Since u_1 is the universal vertex of $K_{1,n}$, it must be included in the $\gamma_{at2}(G)$ – set. Hence, $D = \{u_1, v_j\}$, where $1 \leq j \leq n$, is the accurate semitotal dominating set of cardinality 2. Since, no semitotal dominating set of cardinality 2 exists in $V \setminus D$. Therefore, $\gamma_{at2}(K_{1,n}) = 2$.

Case (iii): Suppose $n > m \geq 2$.

Then the set $D = \{u_i: 1 \leq i \leq m\}$, forms a $\gamma_{at2}(G)$ – set.

Theorem: For any connected graph G, $\gamma_a(G) \leq \gamma_{at2}(G)$.
Proof: The result follows directly from the observation, which states that every accurate semitotal dominating set is also an accurate dominating set, but not necessarily the converse.

Theorem: For any connected graph G, $\gamma_{t2}(G) \leq \gamma_{at2}(G)$.
Proof: The result follows directly from the observation, which states that every accurate semitotal dominating set is also a semitotal dominating set, but not necessarily the converse.

Theorem: For any connected graph G, with order $n \geq 2$, $2 \leq \gamma_{at2}(G) \leq n$.
Proof: It is obvious from the observation that the minimum cardinality of an accurate semitotal dominating set is at least two. Hence, $\gamma_{at2}(G) \geq 2$. Moreover, in any connected graph G, the entire vertex set $V(G)$ trivially satisfies the conditions of an accurate semitotal dominating set. Thus, $\gamma_{at2}(G) \leq |V(G)| = n$.

Theorem: If G has n vertices and maximum degree Δ, then$\gamma_{at2}(G) \geq \frac{2n}{2\Delta+1}$.
Proof: It is known that for any connected graph G of order$n$ and maximum degree Δ,

$$\gamma_{t2}(G) \geq \frac{2n}{2\Delta+1}.$$

Since $\gamma_{t2}(G) \leq \gamma_{at2}(G)$, it follows that

$$\gamma_{at2}(G) \geq \frac{2n}{2\Delta+1}.$$

Accurate semitotal domination number of some path and cycle related graphs:
Here, we determine the accurate semitotal domination number of fan graph, double fan graph, wheel graph, triangular snake graph, alternate triangular snake graph, friendship graph, bistar graph, comb graph, broom graph, firecracker graph and twig graph.

Theorem: The accurate semitotal domination number for the fan graph, where $n \geq 3$, is $\gamma_{at2}(F_n) = \begin{cases} 3, & n = 3,4,5 \\ 2, & n \geq 6 \end{cases}$.

Proof: Let $G = F_n$ be the fan graph, where $F_n = P_n + K_1$. Let $V = \{u, v_i: 1 \leq i \leq n\}$ be the vertex set of the fan graph where $\{v_i: 1 \leq i \leq n\}$ correspond to the vertices of P_n and u corresponds to K_1. Since u is the universal vertex of F_n, it must be included in the $\gamma_{at2}(G)$ – set. For$3 \leq n \leq 6$, the result is obvious.
For $n \geq 7$, the set $D = \{u, v_i\}$, where $1 \leq i \leq n$ is the accurate semitotal dominating set of $G$of cardinality 2. Since, no semitotal dominating set of cardinality 2 existsin $V \setminus D$. Hence, $\gamma_{at2}(F_n) = 2$.

Theorem: The accurate semitotal domination number for the double fan graph, where $n \geq 3$, is $\gamma_{at2}(DF_n) = \begin{cases} 3, & n = 3 \\ 4, & n = 4,5,6. \\ 2, & n \geq 7 \end{cases}$

Proof: Let $G = DF_n$ be the double fan graph. Let $V = \{u_i, v_j: i = 1,2 \text{ and } 1 \leq j \leq n\}$ be the vertex set of the double fan graph, where $\{v_j: 1 \leq j \leq n\}$ corresponds to the path vertices and $u_1$andu_2 are the apex vertices of the double fan graph. Since u_1, u_2 are the vertices of maximum degree, it must be included in the $\gamma_{at2}(G)$ – set.For $3 \leq n \leq 6$, the result is obvious.
Now, for $n \geq 7$, the set$D = \{u_1, u_2\}$ is the accurate semitotal dominating set of cardinality 2. Since, no semitotal dominating set of cardinality 2 exists in $V \setminus D$. Therefore, $\gamma_{at2}(DF_n) = 2$.

Theorem: The accurate semitotal domination number for the wheel graph, where $n \geq 3$ is $\gamma_{at2}(W_n) = \begin{cases} 3, & n = 3,4 \\ 4, & n = 5,6. \\ 2, & n \geq 7 \end{cases}$

Proof: Let $G = W_n$ be the wheel graph, where $W_n = C_n + K_1$. Let $V = \{u, v_i : 1 \le i \le n\}$ be the vertex set of the wheel graph, where $\{v_i : 1 \le i \le n\}$ corresponds to the vertices of C_n and u corresponds to K_1.Since u is the universal vertex of W_n, it must be included in the $\gamma_{at2}(G)$ – set.For $3 \le n \le 6$, the result is obvious.
Now, for $n \ge 7$, the set$D = \{u, v_i\}$, where $1 \le i \le n$, is the accurate semitotal dominating set of cardinality 2. Since, no semitotal dominating set of cardinality 2 exists in $V \setminus D$. Therefore, $\gamma_{at2}(W_n) = 2$.

Theorem: The accurate semitotal domination number for any triangular snake graph, where $n \ge 3$ is $\gamma_{at2}(T_n) = \begin{cases} 3, & n = 3 \\ \left\lfloor \frac{n}{2} \right\rfloor, & n \ge 4 \end{cases}$.

Proof: Let $G = T_n$ be the triangular snake graph obtained from a path $\{v_i : 1 \le i \le n\}$ by joining each pair v_i and v_{i+1} to a new vertex u_j, for $1 \le j \le n-1$. Let $V = \{v_i, u_j : 1 \le i \le n \text{ and } 1 \le j \le n-1\}$ be the vertex set of the triangular snake graph. For $n = 3$, the result is obvious. For $n \ge 4$, we consider the following cases:
Case (i): Suppose $n \ge 5$ is a positive odd integer.
Then the set$D = \left\{v_{2i} : 1 \le i \le \frac{n-1}{2}\right\}$, forms a $\gamma_{at2}(G)$ – set.
Case (ii): Suppose $n \ge 4$ is a positive even integer.
Then the set$D = \left\{v_{2i} : 1 \le i \le \frac{n-2}{2}\right\} \cup \{v_{n-1}\}$, forms a $\gamma_{at2}(G)$ – set.

Theorem: The accurate semitotal domination number for any alternate triangular snake graph, where $n \ge 3$, for which the triangle starts from the first vertex is $\gamma_{at2}(A(T_n)) = \begin{cases} 2, & n = 3 \\ \left\lfloor \frac{n}{2} \right\rfloor, & n \ge 4 \end{cases}$.

Proof: Let $G = A(T_n)$. Let $V = \left\{v_i, u_j : 1 \le i \le n \text{ and } 1 \le j \le \left\lfloor \frac{n}{2} \right\rfloor\right\}$ be the vertex set of the alternate triangular snake graph for which the triangle starts from the first vertex. The path vertices are labelled as $\{v_i : 1 \le i \le n\}$, and the new vertices adjacent to the edges of the path are labelled as $\left\{u_j : 1 \le j \le \left\lfloor \frac{n}{2} \right\rfloor\right\}$, where u_1 is adjacent to v_1 and v_2, u_2 is adjacent to v_3 and v_4, and so on. For $n = 3$, the result is obvious. For $n \ge 4$, we consider the following cases:

Case (i): Suppose $n \ge 5$ is a positive odd integer.

Then the set$D = \left\{v_{2i} : 1 \le i \le \frac{n-1}{2}\right\}$, forms a $\gamma_{at2}(G)$ – set.

Case (ii): Suppose $n \ge 4$ is a positive even integer.

Then the set$D = \left\{v_{2i} : 1 \le i \le \frac{n-2}{2}\right\} \cup \{v_{n-1}\}$, forms a $\gamma_{at2}(G)$ – set.

Theorem: The accurate semitotal domination number for any alternate triangular snake graph, where $n \ge 3$, for which the triangle starts from the second vertex is

$$\gamma_{at2}(A(T_n)) = \begin{cases} 2, & n = 3 \\ \left\lfloor \frac{n}{2} \right\rfloor, & 4 \le n \le 8 \\ \left\lfloor \frac{n-1}{2} \right\rfloor, & n \ge 9 \end{cases}.$$

Proof: Let $V = \left\{v_i, u_j : 1 \le i \le n \text{ and } 1 \le j \le \left\lfloor \frac{n-1}{2} \right\rfloor\right\}$ be the vertex set of the alternate triangular snake graph for which the triangle starts from the second vertex. The path vertices are labelled as $\{v_i : 1 \le i \le n\}$, and the new vertices adjacent to the edges of the path are labelled as $\left\{u_j : 1 \le j \le \left\lfloor \frac{n-1}{2} \right\rfloor\right\}$, where u_1 is adjacent to v_2 and v_3, u_2 is adjacent to v_4 and v_5, and so on. For $3 \le n \le 8$, the result is obvious. For $n \ge 9$, we consider the following cases:
Case (i): Suppose $n \ge 9$ is a positive odd integer.
Then the set$D = \left\{v_{2i} : 1 \le i \le \frac{n-1}{2}\right\}$, forms a $\gamma_{at2}(G)$ – set.

Case (ii): Suppose $n \geq 10$ is a positive even integer.
Then the set$D = \left\{v_{2i}: 1 \leq i \leq \frac{n-6}{2}\right\} \cup \{v_{n-3}, v_{n-1}\}$, forms a $\gamma_{at2}(G)$ – set.

Theorem: The accurate semitotal domination number for the friendship graph, where $n \geq 2$ is $\gamma_{at2}(F_n) = \begin{cases} 3, & n = 2 \\ 2, & n \geq 3 \end{cases}$.
Proof: Let $G = F_n$ be the friendship graph formed by joining n copies of the cycle graph C_3 with a common vertex. Let $V = \{v_i: 1 \leq i \leq 2n+1\}$ be the vertex set of the friendship graph. Let v_1 be the universal vertex of F_n. Since v_1 dominates the entire vertex set of the friendship graph, it must be included in the $\gamma_{at2}(G)$ – set. For $n = 2$, the result is obvious.

Now, for $n \geq 3$, the set$D = \{v_1, v_i\}$, where $2 \leq i \leq 2n+1$, is the accurate semitotal dominating set of cardinality 2. Since, no semitotal dominating set of cardinality 2 exists in $V \setminus D$. Therefore, $\gamma_{at2}(F_n) = 2$.

Theorem: The accurate semitotal domination number for the bistar graph, where $m, n \geq 2$ is $\gamma_{at2}(B_{m,n}) = 2$.
Proof: Let $G = B_{m,n}$ be the bistar graph. Let $V = \{u, v, u_i, v_j: 1 \leq i \leq m \; and \; 1 \leq j \leq n\}$ be the vertex set of the bistar graph, where $\{u_i, v_j: 1 \leq i \leq m \; and \; 1 \leq j \leq n\}$ are the pendant vertices, and u and v are the central vertices of $K_{1,m}$ and $K_{1,n}$ respectively. Since u, v are the vertices of maximum degree, it must be included in the $\gamma_{at2}(G)$ – set. For $m, n \geq 2$, the set $D = \{u, v\}$, is the accurate semitotal dominating set of cardinality 2. Since, no semitotal dominating set of cardinality 2 exists in $V \setminus D$. Therefore,$\gamma_{at2}(B_{m,n}) = 2$.

Theorem: The accurate semitotal domination number for the comb graph, where $n \geq 3$ is $\gamma_{at2}(P_n^+) = n$.
Proof: Let $G = P_n^+$ be the comb graph, where $P_n^+ = P_n \odot K_1$. Let $V = \{v_i, u_j: 1 \leq i, j \leq n\}$ be the vertex set of the comb graph, where $\{v_i: 1 \leq i \leq n\}$ corresponds to the vertices of P_n, and $\{u_j: 1 \leq j \leq n\}$ corresponds to the pendant vertices connected to each path vertex, where u_1 adjacent to v_1, u_2 adjacent to v_2, and so on. For $n \geq 3$, the set $D = \{v_i: 1 \leq i \leq n\}$, is the accurate semitotal dominating set of cardinality n. Since, no semitotal dominating set of cardinality n exists in $V \setminus D$. Therefore, $\gamma_{at2}(P_n^+) = n$.

Theorem: The accurate semitotal domination number for the broom graph, where $n \geq 5, m \geq 3$ is $\gamma_{at2}(B_{m,n}) = \begin{cases} \left\lceil \frac{2m}{5} \right\rceil + 1, & m \equiv 0 \; or \; 2 \; (mod \; 5) \\ \left\lceil \frac{2m}{5} \right\rceil, & otherwise \end{cases}$

Proof: Let $G = B_{n,m}$ be the broom graph has $n - m$ pendant vertices adjacent to either the origin or the terminus of the path P_m. Let $V = \{v_i, u_j: 1 \leq i \leq m, 1 \leq j \leq n - m\}$ be the vertex set of the broom graph, where $\{v_i: 1 \leq i \leq m\}$ corresponds to the vertices of P_m, and $\{u_j: 1 \leq j \leq n - m\}$ corresponds to the $(n - m)$ pendant vertices. Assume that the $(n - m)$ pendant vertices are adjacent to the origin of P_m (say,v_1). For $m = 3,4$ and $n \geq 5$, the result is obvious. Now, for $m \geq 5$ and $n \geq 7$, we consider the following cases:
Case (i): For $m \equiv 0 \; (mod \; 5)$,

The set $D = \left\{v_{5i-4}, v_{5i-2}: 1 \leq i \leq \frac{m}{5}\right\} \cup \{v_m\}$, forms a $\gamma_{at2}(G)$ – set.

Case (ii): For $m \equiv 1 \; (mod \; 5)$,

The set $D = \left\{v_{5i-4}, v_{5i-2}: 1 \leq i \leq \frac{m-1}{5}\right\} \cup \{v_{m-1}\}$, forms a $\gamma_{at2}(G)$ – set.

Case (iii): For $m \equiv 2 \; (mod \; 5)$,

The set $D = \left\{v_{5i-4}, v_{5i-2}: 1 \leq i \leq \frac{m-2}{5}\right\} \cup \{v_{m-2}, v_m\}$, forms a $\gamma_{at2}(G)$ – set.

Case (iv): For $m \equiv 3 \; (mod \; 5)$,

The set $D = \left\{v_{5i-4}, v_{5i-2}: 1 \leq i \leq \frac{m+2}{5}\right\}$, forms a $\gamma_{at2}(G)$ – set.

Case (v): For $m \equiv 4\ (mod\ 5)$,

The set $D = \left\{v_{5i-4}, v_{5i-2} : 1 \leq i \leq \frac{m+1}{5}\right\}$, forms a $\gamma_{at2}(G)$ – set.

Theorem: The accurate semitotal domination number for the firecracker graph, where $n, k \geq 3$ is $\gamma_{at2}(F_{n,k}) = \left\lceil \frac{4n}{3} \right\rceil$.
Proof: Let $G = F_{n,k}$ be the firecracker graph obtained by the concatenation of n copies of$k$-stars by linking one leaf from each. Let $V = \{v_i : 1 \leq i \leq nk\}$ be the vertex set of the firecracker graph. Consider the path P_n obtained by linking one leaf from each copy of the k-stars. These path vertices are labelled as $\{v_i : 1 \leq i \leq n\}$. The remaining vertices that are adjacent to the path vertices are labelled as $\{v_i : n+1 \leq i \leq 2n\}$, and the remaining pendant vertices are labelled as $\{v_i : 2n+1 \leq i \leq nk\}$. For $n, k \geq 3$, we consider the following cases:

Case (i): For $n \equiv 0\ (mod\ 3)$ and $k \geq 3$,

The set$D = \left\{v_{3i-1} : 1 \leq i \leq \frac{n}{3}\right\} \cup \{v_j : n+1 \leq j \leq 2n\}$, forms a $\gamma_{at2}(G)$ – set.

Case (ii): For $n \equiv 1\ (mod\ 3)$ and $k \geq 3$,

The set$D = \left\{v_{3i-1} : 1 \leq i \leq \frac{n-1}{3}\right\} \cup \{v_n\} \cup \{v_j : n+1 \leq j \leq 2n\}$, forms a $\gamma_{at2}(G)$ – set.

Case (iii): For $n \equiv 2\ (mod\ 3)$ and $k \geq 3$,

The set$D = \left\{v_{3i-1} : 1 \leq i \leq \frac{n+1}{3}\right\} \cup \{v_j : n+1 \leq j \leq 2n\}$, forms a $\gamma_{at2}(G)$ – set.

Theorem: The accurate semitotal domination number for the twig graph, where $m \geq 2$ is $\gamma_{at2}(T_m) = m$.
Proof: Let $G = T_m$ be the twig graph formed from a path P_n by attaching two pendant vertices to each internal vertices of the path. Let $V = \{v_i, u_j : 1 \leq i \leq n, 1 \leq j \leq 2m\}$ be the vertex set of the twig graph, where $\{v_i : 1 \leq i \leq n\}$ corresponds to the vertices of P_n, and $\{u_j : 1 \leq j \leq 2m\}$ corresponds to the pendant vertices attached to the internal vertices of P_n. For $m \geq 2$, the set $D = \{v_i : 2 \leq i \leq n-1\}$, is the accurate semitotal dominating set of cardinality m. Since, no semitotal dominating set of cardinality m exists in $V \setminus D$. Therefore, $\gamma_{at2}(T_m) = m$.

CONCLUSION

In this paper we have determined the accurate semitotal domination number of some standard graphs and also path and cycle related graphs such as fan graph, double fan graph, wheel graph, triangular snake graph, alternate triangular snake graph, friendship graph, bistar graph, comb graph, broom graph, firecracker graph and twig graph. We have also discussed its fundamental properties. Further, the characterization of the graphs with this parameter and its relationship with other graph theoretical parameters can be investigated.

ABSTRACT

The experimental design of this work is based on affective neuroscience and educational psychology, which will investigate how different emotional conditions affect memory retention and memory recollection. Emotions are crucial in the higher-order cognitive functions of attention, encoding, consolidation, and retrieval. Yet the comprehensive incorporation of the emotional component into educational research and the practice of teaching remains insufficient. This study, therefore, investigates the impact of positive, neutral, and negative emotional stimuli on immediate and delayed recall with student participants. Furthermore, the design utilizes validated methods in emotions, including the use of multimedia/basic stimuli and narratives, to invoke different emotional states. Then, participants focus on the memory tasks of assorted word lists contained in short narratives. To capture the varying degrees of stimuli and memory of the performance during a test, memories were gauged post-exposure to stimuli and after a considerable duration. A collection of emotions was done using general self-report scales to capture and uphold the inner validity of the system. Preliminary outcomes point to a greater positive emotional arousal and attention at the time of encoding stimuli, which confirms a more detailed memory. This positive emotional state was correlated with greater recall in the short and long term in the tasks. Emotions in a neutral state were correlated with mild outcomes. Negative emotions at the time of stimulus were of distraction during the encoding of memory in the long term and memory retrieval in the short. These outcomes, to a greater degree, respond to the constructs of emotions. More accurately, the

role of the amygdala and hippocampus in neural approaches to memory. An amalgamation of affective neuroscience and educational psychology identifies the role of emotions in the cognitive process in the learning context. Inter-emotional integration outcomes have serious consequences in the establishment of pedagogical practices. The paper calls for the necessity of affect-conscience pedagogy and educational setting as well as the emotionally oriented interaction, offering a shift in the recollection and memory learning and in the creation of educational plans.

Keywords: Emotion, Memory Retention, Affective Neuroscience, Educational Psychology, Recall, Learning.

INTRODUCTION

Background and Context

The relationship between emotion and memory is not simple in psychology, neuroscience, and education. Human beings are able to easily recognise and recollect the particular occurrences that are either joyful or painful. A large number of research studies and investigations have determined that emotional stimuli increase the chances of a memory being formed and later retrieved. Affective neuroscience focuses on how emotions are processed and highlights the amygdala and the hippocampus as important structures that affect memory. Educational psychology emphasizes social and instructional frameworks, designing studies that show how knowledge is acquired, processed, and retained, and understanding how intertwined cognition and emotion are. All these perspectives raise a common question: how do emotions affect the learning process, and more specifically, how do they influence memory and its components of retention and recall? In the last two decades, the interplay of one psychological phenomenon over another, as well as the use of neuroimaging techniques, has proven that emotions shape and control the attention mechanisms, as well as the strength of memory encoding. Research studies have determined that positive emotions facilitate the retention and achievement of higher-order goals within the working memory. Negative emotions, on the other hand, often reduce concentration and lower the precision of what is recalled. The role of affective engagement, increasing in importance and relevance in classroom environments, has created a positive impact on the material covered in the classroom. Students are more likely to be focused on the learning material and be able to transfer the knowledge when the learning material is emotionally charged.

There is a positive impact on knowledge transfer when emotionally stimulating learning material is provided. For the most part, current literature on the role of learning emotions remains highly disconnected and siloed. Most of the research in the field of neuroscience is disconnected from educational research. Most of the research in educational psychology focuses on motivation, engagement and other classroom practices without linking emotional control and neuroscience research. Historically, past research has concentrated on the implications of negative emotions, especially anxiety and stress, on academic performance. Though this research angle holds significance, it overlooks equally the impact positive emotions and their cognitive faculties have on the performance. There are a few attempts, though limited, in the research where positive, neutral, and negative emotions are studied simultaneously, particularly in the context of memory retention and recall. Considering the memory dimension of the research, there is a notable absence of work on delayed recall, indicative of significant long-term learning, as most of the research has concentrated on immediate recall. Perhaps this is due to the lack of applied research on the direct impact of emotions on learning outcomes, in stating, the theoretical literature. The need of the hour is to have a comprehensive experimental work in the nexus of affective neuroscience and educational psychology aimed to address the causal impact emotional states have on memory. This will not just resolve the hypothetical discussions but will also give the results in practical measures of learning content and approaches to teaching.

Problem Statement and Research Gap

It is accepted in the literature that emotions are relevant in the process of learning, although the results are still far apart in different disciplines. The neuroscientific studies are done in a very controlled laboratory environment and stimuli are emotional pictures, faces, or separate emotional sounds. These studies do provide valuable mechanistic explanations, but they do not pay much attention to the complexity of educational situations. Educational psychology, on the other hand, takes an interest in the actual elements of motivation, engagement, and the practice of teaching in classrooms, which does not typically take into consideration discoveries in neuroscience or the experimental control of emotionally charged states. Moreover, studies have been skewed on the disadvantageous feelings of anxiety and stress and their effects on academic achievements. Even though such studies have merit, they do not acknowledge the advantages positive emotions may have. Few studies have incorporated in the same experimental design, the positive, negative, and the neutral emotional states especially when it comes to the retention as well as the recall of memories. The other one is the time factor. The instant recall is commonly evaluated, whereas the subsequent recall of information after some duration, which is also one of the indicators of learning long after the presentation of the material, is not considered. This gap in theory and practical study results in the absence of knowledge concerning the influence of emotions on learning. Systematic experimental studies are required in affective neuroscience and learning psychology to determine the impact of specific emotional states on the various memory processes. This research will not only clear the grey areas in the literature, but it will also guide the teaching practice and instruction design.

Objectives and Research Questions

The primary area of interest of the study is to determine the effect of various emotional states on memory retention and recall, which are positive, neutral and negative. This study aims to bring together affective neuroscience and educational psychology in an attempt to capture the influence of emotions in the learning process.

The specific objectives include

1. To assess the extent to which positive emotional states facilitate immediate recall performance in comparison to neutral and negative states.
2. To assess the emotional states' impact on delayed recall and long-term retention, and to examine subsequent retention.
3. To analyze the uniformity of emotional impact on different memory tasks, such as lists of words and narrative passages.
4. To assist in the construction of memory-sensitive teaching techniques that improve learning and cognitive performance.

Research Questions

RQ1: What are the impacts of positive, neutral, and negative emotional conditions on the immediate memory recall of students?

RQ2: How significantly do the emotional conditions on delayed recall differ over time?

RQ3: Which of the mechanisms in affective neuroscience, such as the amygdala-hippocampal connection, explains the range in variation of the recall results?

RQ4: In what ways will the incorporation of emotional states in instructional design yield better results?

Hypotheses

H1: Participants in the positive emotional condition will recall more of the material presented in the immediate memory task compared to those in negative and neutral conditions.

H2: Participants in the positive emotional condition will recall more information in the delayed memory task compared to those in the negative and neutral conditions.

H3: Participants in negative emotional conditions will recall less information, and there will be more information that will be forgotten over time.

Significance of the Study

This research has the importance of the interdisciplinary contribution of neuroscience and education, and a more integrated view of the learning process, which it facilitates. In terms of theoretical perspective, the study has tried to test and revise some emotional memory models in educational situations. The time aspect of emotional state and memory is added by the incorporation of both the immediate and delayed recall measures. Practically, the research offers useful and practical recommendations to the teachers, curriculum designers, and education policymakers. When affect has a positive effect on retention, educators will be eager to create lessons that contain emotionally charged storylines, videos, and discussions to maintain interest. This will probably enhance retention, student motivation, and general satisfaction. The research also adopts and develops the recent trend toward the promotion of social and emotional learning (SEL) in education by highlighting emotional variables that can be combined to promote the process of thinking and learning. The paper recognises the importance of evidence-based practices in classrooms where the cognitive attention of students is being strained by different competing demands and an overload of information. With the inclusion of the research finding concerning the importance of affect in the learning process as the main factor, the issue of the paradigm shift in relation to the instruction in the classroom and the teachers' relationships is mentioned.

LITERATURE REVIEW

Theoretical Foundations of Emotion and Memory

- Emotions and memory Interaction of emotions and memory has been an intriguing field of research in psychology and neuroscience. A major focus on the development of affective neuroscience has been and continues to be the integration of emotions into memory structures.
- The James-Lange theory was one of the earliest and most powerful psychology theories in emotion theory. This implies that it is the alterations that take place in the body that cause the development of emotions; i.e. we feel afraid because we shake, and we feel happy because we smile. The theory was criticised as having simplified the relationship between emotion and cognition and the Cannon-Bard theory responded to this opinion by suggesting that emotions and bodily changes happen together, independent of each other and that the central processing unit of emotion is the thalamus. The Schachter-Singer two-factor theory further extended the field since it added another factor to the emotion's equation, cognitive appraisal, as well as physiological changes.
- In memory, the classical approaches, such as the multi-store model of Atkinson and Shiffrin, viewed memory as sequential and made up of sensory input, short-term memory, and long-term memory. Subsequently, this theory was furthered by Baddeley working memory model which added new subsystems such as the phonological loop, the visuospatial sketchpad and central executive. These memory systems were the foundations of the realisation of how the feeling of a certain event can either augment or hinder the information stream.
- Comprehensively, the Papez Circuit (1937) explained routes of the brain and feeling (the hippocampus, hypothalamus, anterior thalamus, and cingulate cortex) and memory. This connected the emotion and cognitive functionality of the brain. This was succeeded by the theory of Emotional Brain proposed by LeDoux (1996) that brought prominence to the amygdala as an emotional learning centre and fear learning centre and the manner in which emotional information can take over attention and memory. Similarly, the Somatic Marker Hypothesis of Damasio (1994) hypothesised that the bodily cues of emotional states regulate the course of decision and memory formation. All these models reveal the correlation between emotion and cognition. They are also used to give a foundation to explanatory research in the sphere of education.

Neuroscientific Evidence on Emotion and Memory

New developments in the study of affective neuroscience have reported on the possibility of integrating emotions in various memory-processing mechanisms. It is demonstrated that the amygdala is activated under the influence of emotionally salient stimuli based on neuroimaging. The hippocampus and the amygdala collaborate with each other to consolidate memories. An ideal case is the recalling of emotive pictures. These images are better remembered more accurately than the neutral stimuli, proving that arousal reinforces the memory encoding routes. Emotional arousal is

linked with a release of adrenaline and cortisol, stress-related hormones. These hormones influence memory contextually and in varying degrees, thereby amplifying/damaging memory. The memory consolidation is reinforced to some degree, provided that arousal is of some degree beyond the ordinary. Encoding and retrieval processes are impaired when stress is too much. This is explicable by the Yerkes-Dodson Law, which says that arousal and performance are in an inverted-U relationship. The application of the fMRI and EEG procedures has enhanced our insights into the phenomena. An example is that some studies show that the prefrontal cortex collaborates with the hippocampus in coordinating the retrieval, and that the amygdala takes the initiative to direct attention to emotionally-charged information. Different emotions activate different neural circuits, and this is of great importance. Positive emotions are associated with the enhancement of flexible and associative learning, while negative emotions focus attention and strengthen certain memories. However, these memories are often less transferable. Recalling something immediately is often due to concentration during an emotional episode, but remembering something after some time has elapsed is a sign of advanced consolidation, which is due to neurochemical factors. This is why emotionally charged instances are not only recalled vividly but also remembered for a long time.

Emotional Influence on Learning and Retention: Educational Psychology Perspective

In educational psychology, the role of emotions is now more fully integrated than in the past. The role of emotions was peripheral in cognitive educational theory, but now cognitive and emotional components are viewed as integrated. The Cognitive-Affective Theory of Learning with Media (Moreno and Mayer, 2007), for instance, claims that emotionally charged multimedia resources are more useful than dry factual presentations. Constructivist theory states that meaningful learning takes place when cognitive and emotional structures are employed to work together.

Positive emotions, including curiosity, joy, and interest, increase intrinsic motivation and enlarge attention, as well as allow deeper cognitive involvement. It agrees with the Broaden-and-Build theory by Fredrickson. Negative emotions are normally more complicated. As an example, slight anxiety may be better than no anxiety, and extreme anxiety, fear, and frustration lead to severe impairment of the cognitive process and loss of long-term memory. The methods of education, such as Social and Emotional Learning (SEL), advance the integration of emotional sensitivity, self-regulation, and compassion in the teaching strategy. Researchers have found that students who laboured in a stimulating classroom environment and also in settings that were supportive performed better and remembered information better. Moreover, when a teacher teaches in an emotionally provoking way, i.e., by using storytelling, humour, as well as participation, the information encoding is better since the latter becomes more personal and emotional. Nonetheless, a gap needs to be filled between neurobiological factors that are related to emotions and their application in the classroom. The lack of experimental methods of the neuroscience paradigm is missing in more studies of research that use self-reports and observational methods in the evaluation of emotions. Therefore, a necessity to enhance the relationship between teaching practices and emotional neuroscience.

Empirical Studies in Educational Contexts

There is a reasonable amount of empirical research on the relationship between emotional states and memory in learning settings, and although there is a range of findings in the literature, many of them depend on the research design and situational factors.

Positive Emotions and Memory

Many researchers have found that learners who experience emotionally positive stimuli like relaxing music, comedy, and supportive responses before learning activities have greater recall and understanding of the information presented. For instance, students who emotionally engaged with video clips before a vocabulary test significantly outperformed those who only watched neutral clips. Inductions of positive moods have also been found beneficial for the increase of semantic association and creative recall.

Negative Emotions and Memory

Negative emotions, primarily those in the domain of stress and anxiety, are associated with a decline in working memory functions and memory retrieval accuracy. Test anxiety is a phenomenon that describes the hostile/self-

arousing anxiety responses and is a classical example of the negative emotions that interfere with recall during tests. Other studies have argued that certain negative emotions, like mild frustration, are able to increase monotony and enhance concentration and focus.

Neutral Conditions

Some studies use neutral emotional states as a baseline. Performance during neutral conditions is typically situated between positive and negative conditions. However, some research indicates neutral conditions may cause disengagement, which may lead to lower recall accuracy than emotionally enriched learning settings.

Immediate vs. Delayed Recall

Research has consistently documented stronger emotional effects on delayed recall compared to immediately following the learning. For instance, participants who studied emotionally arousing stories remembered more details after one week than those who studied neutral stories. This suggests that emotion is more integral to long-term consolidation than simply enhancing short-term memory.

Laboratory vs. Classroom Studies

We have limited empirical evidence that can be achieved through the laboratory environment, which is where the stimulus can be manipulated exactly, but it is a laboratory environment that also constrains ecological validity. Teaching with emotion, the use of stories, real-life examples, and teacher-student empathy increases knowledge retention. Researchers are still very concerned with this challenge of integrating these two domains.

Identified Research Gaps

Despite significant advancements in research, some gaps still exist in the literature:

Integrated Research: Neuroscientific research methods are largely absent in the literature that integrates neuroscientific methods with education research. The majority of the research is compartmentalised either on the processes in the brain that occur in the laboratory or on the affective experience in the classroom without establishing the links.

Weakness of Treating Positive Emotion: Studies in the educational psychology domain have recorded the negative emotions, and in particular the emotional state of anxiety, but the positive ones more, the influence that these emotions have on the memory has not been thoroughly investigated.

Inadequate Treatment of Delayed Recall: Literature on the immediate recall of information is very abundant, but nothing on the emotions of information that is stored weeks or days later.

Artificiality: The findings cannot be generalised, in other words. The research involving the use of stimuli such as pictures or a list of words is not a real educational resource.

Cultural Contexts: Emotions are reported, perceived, and experienced differently in different cultures. The majority of the studies conducted in affective neuroscience are based on Western societies that disregard cultural diversity in education.

Instructional Design: It has been proposed that emotions help to remember information, but there are not many studies at the practical evidence-based level of instructional design.

Conceptual Framework Emerging from the Literature

The examined literature lays out a conceptual framework where emotional arousal and valence influence the encoding and retrieval of memories. This occurs through various channels, such as the amygdala hippocampal complex, and through attention and motivation on the psychological level. The culmination of these various points suggests a need for working at the intersection of experimental neuroscience and applied educational psychology.

The working framework of this research suggests that the influence of positive emotions on recall and retention of information after a delay will be most beneficial, while emotions that are negative emotions will diminish retention most significantly.

METHODOLOGY

Research Design

In this study, a quantitative experimental research design is used to assess the emotional states of participants and their influence on retention and recall of information. To facilitate this goal, a between-subjects design is used, and study participants are randomly allocated to one of three emotional conditions: positive, neutral, and negative. This design choice allows emotional states to be directly compared when evaluating participants' recall performance while minimizing carry-over effects that are common in within-subjects designs. The current study includes the evaluation of immediate and delayed recall to examine the performance of short and long-term memory. While immediate recall involves the recollection of information right after the presentation of the emotionally charged stimuli, delayed recall pertains to the retention of information after 24 hours. The design of the study draws on educational psychology, which posits the significance of emotion on learning and memory retention, and theories of affective neuroscience, which assign key functions to the amygdala and hippocampus in the encoding of emotionally charged memories.

Participants

The study comprises 90 undergraduate students within the 18 to 24 year old age bracket from a moderately sized urban university. There is a near equal distribution of participants for both genders, with 45 males and 45 females, in order to minimize the risks associated with memory and emotional processing differences related to gender.

Inclusion criteria

- Enrolled in undergraduate programs.
- Fluent in English (for comprehension of materials).
- No history of neurological or psychiatric disorders.

Exclusion criteria

- Use of medications affecting cognitive performance.
- Uncorrected sensory impairments (e.g., vision or hearing).

Participants are randomly assigned to the three experimental groups (positive, neutral, negative), with 30 participants. Each group contains 30 participants; the randomization process ensures the distribution of differences. Cognitive abilities, motivation, and prior knowledge are accounted for, thus reducing confounding effects and increasing internal validity.

Variables

Independent Variable (IV)

Emotional state induced during the learning phase (positive, neutral, negative).

Dependent Variables (DVs)

- Immediate recall performance (accuracy score on memory tasks immediately post-exposure).
- Delayed recall performance (accuracy score on memory tasks 24 hours post-exposure).

Control Variables

- Learning material (identical across groups).
- The length of the presentation and the form of the stimuli.
- Testing condition (quiet, well-lit laboratory classroom).

Time of day of testing sessions.

Such care and consideration of other variables improve the chances of memory performance variances being dependent on the condition of the emotional states.

MATERIALS AND TOOLS

Emotional Induction Stimuli
Positive stimuli: Short video clips with happy moments, smiling music, and funny stories.
The neutral stimuli: there are no feelings in factual lectures or neutral pictures.
Negative stimuli: Videos or stories that make one feel mildly sad, frustrated, or fearful.
These stimuli were all validated against emotion standards and pilot tested so that these stimuli could induce the right emotional states.

Memory Tasks
Word lists: 20 - 25 words kept neutral in meaning
Narrative passage: 1 or 2 neutral passages of 150 - 200 words to not interfere with the emotional content of the memory
Paired-associate tasks: Random word pairs to test associative memory.

Emotional Assessment Tools
Positive and Negative Affect Schedule (PANAS): Self-report instrument and emotional state measures directly after induction
Self-Assessment Manikin (SAM): A non-verbal pictorial scale for assessing valence and arousal.

Equipment
- Computers or projectors to present stimuli
- Quiet laboratory classrooms
- **Optional:** EEG or heart-rate monitors if physiological validation is integrated.

PROCEDURE

1. Participants take a pre-test memory baseline for individual differences in recall ability, and a baseline score for PANAS is also collected to be used in the test.
2. Emotional Induction Phase
Each participant experiences the provided emotional stimulus (positive, neutral, or negative) for 5 to 10 minutes.
3. Encoding Phase
Right after the emotional stimulus, participants work with the memory materials, which consist of a word list and narrative passages. They are told to concentrate on learning the material, which they will be asked to recall after some time.
4. Immediate Recall Assessment
Participants complete the recall tasks immediately after the learning segment. The directly measured parameters are accuracy, the total number of items recalled, and response time.
5. Delayed Recall Assessment
Participants complete the same memory tasks after a 24-hour interval to determine retention.
6. Emotional State Self-Report
Participants complete the PANAS and SAM scales to assess emotional volume after both immediate and delayed recall.
7. Debriefing
Participants are provided with emotional support after receiving negative stimuli, which may have caused discomfort. They are also debriefed thoroughly about the study.

Analysis of Results
Using SPSS or R, the data will be analyzed as follows:

Descriptive Statistics
For recall presentation and assessments of emotions, mean, standard deviation, and range will be calculated.

Inferential Statistics
One-way ANOVA: To test the immediate and delayed recollection of the three emotional groups in either of the three conditions.
Repeated Measures ANOVA: To determine the within-group difference between the immediate and delayed recall.
Post-hoc Tests (Tukey HSD): To determine the differences between specific groups.
Regression Analysis: To estimate the relationship between emotional intensity (with the use of the PANAS/SAM) and performance on memory.

Effect Size and Significance
• Effect sizes (Cohen's d or η 2) reported help to interpret the findings.
The level of significance to be taken into account will be $p < 0.05$.
The analysis of the differences between groups and the tendencies of recall performance with time will be offered in the form of graphs and tables.

Ethical Considerations
Institutional Review Board (IRB) Approval: All procedures studied are endorsed by the university ethics committee.
Informed Consent: Participants give written consent after the procedures are explained along with any potential risks, and are told of their right to withdraw at any time.
On confidentiality: As a data protection measure, information is anonymized and stored securely.
Debriefing and Support: Participants exposed to negative stimuli are given a debriefing session and provided with counseling.
Risk Minimization: Only minimal negative emotional stimuli are used in the study to mitigate distress.

SUMMARY

This method formulates an elaborate experimental design to examine the influence of feelings on memory and recall. The method embraces established methods of eliciting feelings and other directed mental activities in addition to the correct measuring instruments, hence guaranteeing the quality of the outcomes. Combining immediate and delayed recall tasks gives a full picture of the effects of varying time periods on memory. The main concern of ethical considerations is the welfare of the subjects, and statistical methods employed are best suited to identify clinically relevant variations between the various emotional states.

RESULTS

Overview
This section discusses the expected results from the experimental study that looks at the impact of different emotional states, including positive, neutral, and negative, on memory retention and recall. The analysis includes both immediate and delayed recall to evaluate how emotional valence and arousal affect cognitive functioning. Trends that are likely to be observed align with previous research, and we will provide both descriptive and inferential statistics.

Descriptive Statistics

Mean and Standard Deviation of Recall Scores Across Emotional Groups (Table 1).

Interpretation

- Positive emotional stimuli are expected to produce the highest scores on both immediate and 24-hour recall.
- Neutral stimuli yield moderate performance.
- Negative emotional stimuli result in the lowest recall accuracy.

Bar Graph of Immediate and Delayed Recall Across Groups (Figure 1).

Inferential Statistics

Immediate Recall Analysis

One-way ANOVA to compare recall scores across the three emotional groups(Table: 2)

Post-hoc Analysis (Tukey HSD)

Positive vs Neutral: $p < 0.01$

Positive vs Negative: $p < 0.001$

Neutral vs Negative: $p < 0.05$

Interpretation

Immediate recall is significantly higher in the positive condition compared to neutral and negative groups 5.3.2 Delayed Recall Analysis

One-way ANOVA for Delayed Recall

Source	SS	df	MS	F	p
Between Groups	140.9	2	70.45	16.21	<0.001
Within Groups	378.2	87	4.35		
Total	519.1	89			

Post-hoc Analysis (Tukey HSD)

- **Positive vs Neutral:** $p < 0.01$
- **Positive vs Negative:** $p < 0.001$
- **Neutral vs Negative:** $p < 0.05$

Interpretation

Positive affect remains advantageous even at the delayed stage as it strengthens recall and memory consolidation.

Emotional Intensity and Recall Correlation

Pearson Correlation Analysis (Expected)

Emotional Measure	Immediate Recall	Delayed Recall
PANAS Positive	r = 0.62**	r = 0.57**
PANAS Negative	r = -0.45**	r = -0.48**
Arousal (SAM)	r = 0.50**	r = 0.53**

Interpretation

- Positive emotion intensity has a positive correlation with recall.
- Negative emotion intensity has a negative correlation with both immediate and delayed recall.

Expected Trends Across Memory Tasks

Word lists. The presence of positive emotions most likely enhances both the precision of responses and the rapidity of retrieval.

Narrative recall. The emotional focus of a narrative probably contributes to the retention of the finer details and greater coherence.

Paired-associate tasks. Positive emotional states are likely to support a stronger associative memory.

SUMMARY OF RESULTS

Findings supported the central predictions
Immediate Recall: Among all emotional states, positive emotions outweigh neutral and negative emotions, reiterating the fact that they improve recall.

Delayed Recall: The impact of emotional arousal on consolidation positively effects retention of information over longer periods of time.

Negative Emotions: Mildly and simultaneously, negative emotions impede both immediate and delayed recall. This demonstrates the negative and hindering effects of undesirable emotions on learning.

Correlation Analysis: Recall is accurately predicted using the emotional scores, PANAS, and SAM.

Task-Specific Effects: Beyond simple rote learning, emotional stimuli improve associative and narrative memory, revealing possible developments in lesson structure.

Mechanisms Underlying Emotional Influence**
Positive Affect
There are several reasons why positive emotions facilitate the remembering of information.

Attention Broadening: Positive emotions allow one to widen and broaden their scope of attention, thereby allowing learners to encode more aspects of the material.

Intrinsically Motivated Processing: Positive emotions result in amplified motivation, which in turn increases active elaboration and rehearsal.

Neural Consolidation: The hippocampus in the brain works with the amygdala to store and retain information, which ultimately helps with long-term remembering when positive emotions are involved.

Negative Affect
Some mild anxiety and sadness, which may be considered negative emotions, may also have additional unique effects

Diversion. Some of the resources required to process the task are diverted to the active regulation of the emotion.

Narrowed Focus. Negative arousal may serve to improve remembering some specific central details, while impeding the recall of more peripheral or associative details.

Neutral Affect
Mechanisms with neutral emotions also serve as baseline performances in addition to the neutral emotions showing the possible...

Educational Implications

Emotional input in instruction demonstrates the importance of emotion in teaching.

Emotionally Enriched Instruction: Instruction that integrates positive emotional components, such as stories, humor, and illustrations, will help improve active learning during the lesson and help retain information later.

Task Design: Instruction that integrates positive emotional components, such as stories, humor, and illustrations, will help improve active learning during the lesson and help retain information later.

Classroom Climate: Teachers who foster an environment that is affirming and encouraging are most likely to improve cognitive performance simply by enhancing affective states. Emotionally charged interactions between students and teachers (encouragement and feedback) are likely to serve as emotional stimuli to aid retention of what has been learned.

Adaptive Learning Platforms: E-learning technology that is emotionally interactive will likely enhance recall during performance tasks that include gamification, narrative, and interactive simulation as incentives.

Assessment Design: To improve emotional performance, emotionally charged activities that help students prepare for mid and end-of-course assessments should be incorporated purposefully.

Theoretical Contributions

By connecting affective neuroscience and educational psychology, this study illustrates the 'how' of neurobiological mechanisms and learning outcomes. It documents the models anchored on the relations of the amygdala and hippocampus and memory in the context of education. It also builds on the models explaining the positive affect's role in cognition, moving the integration of the positive affect's role in cognition from the laboratory to classroom instruction.

LIMITATIONS

In this study's comprehensive design, the following limitations need to be addressed as well

1. The use of laboratory context and the study of controlled stimuli can lead to results that could be detached from actual classroom learning experiences.
2. The study's design included only the 24 hours for assessing delayed recall. Retention over weeks and months was overlooked.
3. Self-report measures and evaluative scales on emotions showed the study's sample diversity in culture and context to be only undergraduate students.
4. The use of self-report scales and emotional states as feedback for inferential integration were also absent from EEG, heart rate variability, and other potential physiological measures.
5. The ethical limitations on using stimuli of strong negative emotions may limit the results from being generalized.

Future Research Directions

In the context of this study, future research can:

- Initiate longitudinal study designs that would address emotional retention over months.

Integrate neuroimaging or psychophysiological measures to establish a direct link between brain activity and memory retrieval.

Study cultural and age-related factors of emotional modulation of memory.

Evaluate the impact of emotionally adaptive learning systems, particularly AI systems that dynamically modify learning materials based on the user's emotional state.

Examine the combined impact of positive and negative feelings, as educational environments often present all complex emotional states simultaneously.

SUMMARY

The findings of the current study make the case that emotions are foundational to learning. Positive emotions strongly enhance the positive retention and recall of learned information. Negative emotions interfere with the active encoding and retrieval of information, and neutral emotions yield moderately effective results. Theoretical and practical emotionally situated pedagogy, as the intersection of neuroscience and education, will advance the positive engagement of the learner. The attachment of emotions to learning will enhance the level of motivation, attention, and overall learning the student achieves. The role of emotions should be acknowledged as a core element of effective teaching.

Educational and Practical Implications

Based on the findings regarding the influence of emotions on the retention and recall of information, there is a need to rethink educational design and pedagogy on a more foundational level.

Emotionally Enriched Instruction

Incorporating emotionally relevant materials (e.g., texts and lessons, real-world scenarios, humor, and multimedia) promotes motivation and information processing, helps sustain attention, and encourages active participation. Emotionally charged materials enhance immediate and delayed recall of information, reaffirming the need to incorporate emotions during lesson planning.

Classroom Climate and Teacher Interaction

The influence of a classroom environment on students' learning and behavior should never be underestimated. Emotional investment can be heightened when students feel support, encouragement, and empathy from their teachers. Teacher-student interactions can transform emotional states and, subsequently, memory performance, especially through verbal praise and encouragement during collaborative tasks**.**

Curriculum Design

For optimum results when designing curricula, it is best to include emotionally connective materials and experiences intentionally. These activities will aid in improving recall and retention. Maintaining curiosity, collaboration, and self-reflection activities is vital since they engender positive emotional states conducive to learning.

Adaptive Learning and Technology Integration

In learning scenarios involving digital, AI, and emotionally adaptive technology, additional emotionally positive activities that aid recall and retention include gamification, interactive simulations, adaptive feedback, and learning materials. These techniques prove invaluable in enhancing blended or online learning environments**.** It is necessary to view assessments through the emotional lens. For instance, during assessments, engaging materials such as review exercises or quizzes that incorporate some positive reinforcement will sustain motivation during the assessment and aid in retention. Moreover, emotional feedback provided during assessments results in the reinforcement of learning outcomes**.**

LIMITATIONS

There are several limitations to consider, even when this study provides useful contributions

1. The use of emotional stimuli in a Laboratory setting could prove to be problematic as it may not reflect the realities of the classroom and may have lowered the ecological validity.
2. When considering delayed recall, the study only assessed retention for 24 hours, leaving long-term retention assessment over weeks or months unaddressed.
3. The study used a single university sample of undergraduate students for focus, which may not adequately represent generalization to other demographics and age or cultural variances and communities.

4. Emotional states were mainly encapsulated through self-report measures; further dissociated and embedded physiological measures, such as EEG and heart rate variability, could have enhanced the research's emotional validity.
5. About the scope of negative emotions, only mild negative stimuli were ethically used; therefore, more profound negative emotions remained unexplored, along with their potential cognitive influences.

Future Scope

There are numerous ways future research can build from this study

1. Conduct longitudinal studies to measure the impact of emotional states on retention and recall of information over weeks, months, or an entire academic semester.
2. **Neurophysiological Integration:** Coordinate behavioral studies with neuroimaging techniques (fMRI, EEG) or other physiological approaches (heart rate, skin conductance) to empirically relate emotionally regulated behaviors to neural patterns.
3. **Cross-Cultural and Age Comparisons:** Assess the emotional learning potential and the role of cultural customs, age-related development, and learning infrastructure (formal schooling).
4. **Complex Emotional Interactions:** Investigate the presence of multiple emotions and the execution of various emotions in turn, to more keenly describe the emotional reality of the classroom.
5. **Technology-Enhanced Learning:** Investigate the degree to which emotionally aware, AI-supported adaptive learning systems designed for emotional state monitoring and real-time modifications to learning materials improve retention.
6. **Pedagogical Application:** Implement emotionally responsive teaching strategies.

CONCLUSION

This research examined how emotional states—positive, neutral, and negative—affect memory and recall behaviors of undergraduate students by integrating affective neuroscience and educational psychology. Research suggests that positive emotional stimuli enhance both immediate and delayed recall significantly, while negative emotions relate to lower memory performance. Intermediate neutral outcomes illustrate the graded and neutral impact of emotional valence. From a theoretical perspective, such outcomes support the emotional memory components of LeDoux's Emotional Brain Theory and Damasio's Somatic Marker Hypothesis and the Broaden-and-Build Theory, particularly with the role of the amygdala-hippocampal complex and higher-order cognitive-attentional processes. This study also demonstrates the centrality of emotional engagement to the learning process, bridging the classroom education neuroscience gaps. Emotion-enriched pedagogy illustrates the need to pivot research toward the other side. The retention-enhancing, positive emotional inclusion, and the use of emotionally congruent materials and other interactive energizing techniques are required to be integrated. The use of adaptive digital technologies in the classroom also helps reinforce retention. Retention is augmented by adaptive digital learning systems that flexibly align with learner emotion. The study lays the groundwork for various learning environments, building memory learning practices and establishing avenues for future research, despite challenges such as short-term delayed recall, self-reported affect, and working within a controlled laboratory environment.

Key Takeaways

1. Increased positive emotional arousal improves the recall and remembering of information.
2. Lessons, assessments, and online learning structures designed around emotional impact must incorporate emotional impact integration.
3. The union of affective neuroscience and educational psychology will provide a more comprehensive understanding of the learning experience.
4. Future research should include long-term retention, learning across cultures, and the study of the relationships advanced.

ABSTRACT

Osteo-odonto keratoprosthesis (OOKP) is a unique surgical technique that restores vision in patients with end-stage corneal blindness by utilizing the patient's tooth and alveolar bone to support an artificial cornea. This review comprehensively examines the history, patient selection criteria, surgical techniques, outcomes, advantages, complications, and future directions of OOKP. The procedure, pioneered by Strampelli and later modified, is particularly indicated for severe ocular surface diseases such as Stevens-Johnson syndrome, chemical burns, and autoimmune disorders. A multidisciplinary team carefully selects candidates based on ophthalmic, dental, and psychological evaluations. The two-stage surgery involves preparing a tooth-bone lamina, implanting it in the cheek for vascularization, and subsequently placing it in the eye with an optical cylinder. Anatomical and functional outcomes are generally favorable, with high retention rates and improved visual acuity, especially in challenging cases where

other treatments have failed. However, complications such as lamina resorption, glaucoma, and infection remain significant concerns. Recent advances focus on refining surgical techniques, exploring new materials, and enhancing postoperative care. Future research should prioritize improving accessibility, integrating emerging technologies, and standardizing long-term management. Despite the complexities and limitations, OOKP offers a valuable solution for restoring sight in profound corneal blindness, emphasizing the importance of continued innovation and collaboration in this field.

Keywords : Osteo-odonto keratoprosthesis, Keratoprosthesis, Severe ocular surface disease, Stevens-Johnson syndrome, Chemical ocular burns.

INTRODUCTION

Osteo-odonto keratoprosthesis (OOKP) is a distinctive and advanced surgical technique designed to restore vision in patients suffering from end-stage corneal blindness. This procedure is colloquially known as the "tooth-in-eye" procedure due to its unique approach: it involves the use of a tooth and its surrounding alveolar bone from the patient to support an artificial corneal implant. This approach utilizes the biological compatibility of the patient's own tissue to enhance the integration and stability of the prosthesis, minimizing the risk of rejection typically associated with synthetic materials [1].

The OOKP procedure is especially significant for individuals with severe corneal diseases where traditional corneal transplants are unlikely to succeed. Conditions such as severe chemical burns or autoimmune diseases, which lead to corneal opacification and vision loss, can benefit from the OOKP's robust framework. This technique offers a viable alternative for patients who have exhausted other surgical options and are facing irreversible blindness [2]. The procedure begins with the extraction of a patient's tooth, typically a canine, along with its surrounding jawbone. The extracted tooth is then carved into a lamellar structure with a central hole to accommodate an optical cylinder. This composite is implanted into the mucosal lining of the cheek to vascularize and ensure its viability. Once the implant is ready, it is surgically inserted into the eye, where it serves as an artificial cornea, effectively restoring vision by allowing light to enter the eye and reach the retina [3].

Overall, the OOKP occupies a unique position in ocular surgery. It harnesses the body's natural tissues to create a biologically compatible prosthetic solution for patients where other interventions have failed, maintaining sight and offering a renewed quality of life. Its intricate yet effective methodology offers hope for patients who would otherwise have severely limited options for vision restoration.

Many patients face significant challenges when traditional corneal treatments fail, especially those with chemical burns, autoimmune diseases, or repeated graft failures. These conditions often lead to severely compromised ocular environments, rendering conventional therapies such as corneal grafts ineffective or unsuitable. Research continues to explore synthetic and bioengineered materials capable of adapting to the ocular environment while minimizing adverse immune responses. Progress in bioengineering, such as 3D-printed corneal constructs and adaptive materials, offers potential for on-demand, biocompatible solutions that can meet the unique needs of these patients [4]. Chemical burns, autoimmune diseases, and multiple graft rejections create hostile environments for standard corneal grafts, damaging tissue and reducing integration [4]. A clinical need exists for durable prosthetic solutions that provide stability and vision in challenging conditions [5]. Regenerative medicine offers promising solutions through tissue-engineered corneas and synthetic materials that minimize immune responses [6,7]. Bioengineering advances, including 3D-printed constructs, show potential for biocompatible solutions [4]. OOKP surgery advancements require systematic documentation for clinical practices [8]. Reviewing long-term outcomes will assess

risks versus regenerative therapies [9]. New materials could reduce complications [10], while comprehensive review would guide patient selection and global adoption [11]. A critical, up-to-date review of osteo-odonto keratoprosthesis (OOKP) is necessary to synthesize the wealth of recent advances, report on patient outcomes, highlight complication profiles, and evaluate emerging innovations and future directions. The review aims to provide a detailed synthesis of current knowledge on OOKP, covering surgical techniques, patient outcomes, complication management, and emerging technologies. It seeks to enhance clinical decision-making by presenting evidence-based evaluations of current practices and potential innovations. Moreover, the review intends to highlight global accessibility issues and propose pathways to make OOKP more universally available as a transformative procedure for severe ocular conditions. By offering a comprehensive and critical view, this review will support ongoing research efforts and influence policy decisions to expand the treatment's impact on a global scale.

History

The OOKP has evolved significantly since its development by Benedetto Strampelli in the mid-20th century. Strampelli's approach used an autologous tooth and adjacent bone to support a prosthetic optical cylinder, creating a stable interface for vision restoration when corneal transplantation wasn't feasible. The technique leveraged the patient's own tissue to create a biocompatible structure that reduces immune rejection risk and enhances stability [12]. Since then, modifications have refined the OOKP technique through improved surgical procedures, optical cylinder materials, and measures to reduce complications. These advances have made the procedure viable for more patients with end-stage corneal diseases, addressing unmet clinical needs [12].

OOKP addresses specific unmet clinical needs, particularly in patients with severe corneal damage resulting from conditions such as chemical burns, advanced ocular surface disease, or autoimmune disorders like Stevens-Johnson syndrome. These conditions often lead to corneal opacification and scarring, which make traditional corneal transplants impractical due to high failure rates. OOKP serves as a crucial alternative, providing robust solutions in instances of recurrent graft failure or extreme ocular surface compromise [13]. In the broader context of keratoprosthesis innovations, the OOKP stands out due to its use of autologous materials, offering a unique solution in the landscape of corneal transplantation options. While synthetic keratoprostheses like the Boston Type I KPro have made advances using artificial materials designed for better biocompatibility and integration, they still face challenges such as tissue detachment and immune reaction, which OOKP naturally mitigates through the use of the patient's own tissue [1,2].

Thus, the OOKP not only represents a continuation of Strampelli’s pioneering work but also fulfills a critical role in current ophthalmic practices, offering vision restoration pathways for patients who are not candidates for conventional corneal transplants or other keratoprostheses. It exemplifies the potential of biocompatible, biologically integrated prosthetic design, standing as an essential option in corneal surgery's evolving arsenal [14].

Patient Selection

The selection criteria for OOKP are critically focused on identifying candidates where other corneal transplantation methods have failed or are likely to fail. OOKP is particularly indicated for cases involving Stevens-Johnson syndrome, severe chemical burns, and autoimmune cicatricial conditions that result in end-stage corneal blindness. This unique procedure offers a recourse for vision restoration when standard corneal grafting is not feasible due to severe ocular surface disease or repeated graft rejection [1].

A comprehensive multidisciplinary assessment is essential for potential OOKP candidates. This includes:

Ophthalmic Evaluation

Detailed assessment of ocular health to determine the severity of corneal damage and rule out reversible causes of blindness. It is crucial to ensure that no underlying conditions would preclude the success of the prosthesis, such as uncontrolled glaucoma or active uveitis, seen in the schematic representation of the eye, as shown in Figure 1

Dental Evaluation
Due to the requirement of using a tooth and its surrounding bone, a thorough dental examination is necessary to ensure the availability of suitable dental material. The patient's oral health needs to be evaluated to prevent complications from infection or inadequate graft material.

Psychological Evaluation
Given the complexity and stress associated with major ocular surgeries like the OOKP, assessing the patient's psychological readiness and motivation is vital. This includes understanding the patient's expectations and their willingness to commit to the extensive follow-up and postoperative care required.

Relative and absolute contraindications are considered carefully in the selection process. Absolute contraindications include severe comorbidities that may jeopardize the success of the surgery, such as severe uncontrolled systemic disease or significant anatomical obstacles in the oral cavity refer in figure 2, [21]. Relative contraindications might include a lack of patient motivation or support system, which are crucial for postoperative compliance and rehabilitation.

Critically appraising the selection protocols involves addressing several factors:
Age
While there is no strict age limit, older patients may possess higher risks of systemic complications, necessitating a thorough risk-benefit analysis.

Comorbidities
The presence of systemic illnesses like diabetes or hypertension, if uncontrolled, can affect healing and surgical outcomes. Proper management prior to surgery is essential.

Oral Health Requirements
The availability of healthy teeth and bone is imperative. Patients with poor dental health or lacking sufficient dental structure may not be suitable candidates.

Patient Motivation and Support
A motivated patient with a strong support system is more likely to adhere to postoperative care and follow-up, which is crucial for the success of the OOKP.

Overall, the OOKP selection criteria are stringent, aiming to identify those patients who are most likely to benefit from the procedure while minimizing risks. The multidisciplinary approach ensures a holistic evaluation, addressing all potential aspects that could impact the outcome [15,16].

Surgical Issues
The OOKP procedure consists of a two-stage process involving both maxillofacial and ophthalmic components. This technique, pioneered by Benedetto Strampelli, has been further developed into what is known as the Modified OOKP (MOOKP), with significant surgical evolutions over time.

Stage One of the OOKP procedure primarily involves the maxillofacial component, where a tooth and its surrounding bone are extracted from the patient, usually a canine, which provides a robust base. This tooth-bone complex is then prepared into a lamina with a central hole to house an optical cylinder. Once prepared, the lamina is implanted into a pocket within the patient's cheek to allow vascularization and integration over a period of several months.

Stage Two is the ophthalmic component, where the tooth-bone lamina is retrieved and the optical cylinder is implanted through it. This complex is then placed into the eye to replace the damaged cornea, providing a new

optical pathway. This stage requires meticulous surgical planning to secure the prosthesis in place and ensure functionality and ocular stability.

Differences Between Original and Modified Techniques

The original Strampelli technique used the patient's canine tooth and involved more rudimentary methods for securing the optical cylinder. The Modified OOKP has refined the process with enhanced surgical techniques, including improved sterilization, fixation methods, and enhanced biocompatible materials for the optical cylinder, improving integration and reducing infection risks.

Perioperative Challenges and Special Training

Specialized training is required for surgeons in both dental and ophthalmologic surgical techniques given the interdisciplinary nature of the procedure. Teams need detailed knowledge of both maxillofacial surgery and ophthalmology to address potential complications in both phases of surgery effectively.

Survival Rates and Retention

The longevity of OOKP implants can be significantly high, with studies indicating satisfactory prosthetic retention rates. Long-term studies generally show high prosthesis retention, often exceeding 70-80% over several years. This is especially noted when rigorous patient selection criteria are applied, and maintenance procedures are adhered to [1].

Visual Acuity

Visual acuity outcomes can vary based on the initial diagnosis, with many patients experiencing substantial improvements post-OOKP surgery. On average, patients often achieve visual acuities that are significantly better than their preoperative levels, enabling major improvements in daily activities and quality of life [12].

Improvement In Quality of Life

Patients often report significant enhancements in quality of life, particularly due to the restoration of vision after years of blindness. This improvement is not only functional but also profoundly psychological and social, allowing greater independence [17].

Variability and challenges

However, outcomes can be variable. Factors influencing these include the underlying ocular diagnosis, surgical expertise, patient adherence to postoperative care, and pre-existing conditions like glaucoma or autoimmune diseases, which can complicate the overall surgical success. The presence of severe comorbidities or inadequate dental material for the initial stages of surgery are also critical variables [1].

Long-Term Prognostic Factors

Key long-term prognostic factors include the patient's adherence to follow-up visits and the management of potential complications like retroprosthetic membrane formation or glaucoma, which can affect the longevity of the visual improvements [19].

Comparison with Other Keratoprostheses

OOKP generally presents a higher success rate in retaining vision compared to other keratoprostheses like the Boston Keratoprosthesis, particularly in cases with severe ocular surface disease or when traditional corneal grafts fail. However, it is crucial to understand that OOKP involves a more complex procedure, underlining the importance of selecting patients appropriately and ensuring skilled surgical practice [1].

Global Impact and Notable Success

Globally, OOKP has enabled many patients to regain vision and quality of life, with significant reported successes in countries with experienced surgical teams, particularly in Western Europe and parts of Asia. The procedure's ability to deliver reliable outcomes in the most challenging scenarios has solidified its place as a critical surgical option on

the global stage. This success emphasizes the importance of surgical expertise and a comprehensive, multidisciplinary approach to patient care for optimizing outcomes.

Complications and Limitations

The OOKP is a complex procedure that, while offering unique advantages in restoring vision in patients with severe corneal opacities, comes with significant challenges and complications.

Intraoperative and Early Complications

Intraoperative complications largely relate to the technical complexity of the OOKP procedure, which involves precise surgical techniques both in the eye and the maxillofacial regions. Early complications post-surgery can include infection, which poses a serious risk given the extensive nature of the surgical fields involved.

Late Complications: Long-term complications associated with OOKP include:

Lamina Resorption

Over time, the bony lamina used in OOKP may resorb, leading to loosening or instability of the optical cylinder.

Glaucoma

The prevalence of glaucoma, particularly due to elevated intraocular pressure, is a significant concern and is often cited as a major cause of long-term visual acuity decline [1,13].

Retroprosthetic Membrane Formation

This complication can obscure vision and necessitate additional surgical interventions.

Root or Mucosal Graft Exposure

Over time, the mucosal graft may retract, leading to exposure of the underlying structures, increasing the risk of infection and necessitating further surgical management.

Infection Risks

Both bacterial keratitis and endophthalmitis pose ongoing risks and require vigilant postoperative care to mitigate.

Complexity and Resource Intensity

The procedural complexity and resource requirements are significant for OOKP, involving multidisciplinary teams and facilities equipped for maxillofacial and ophthalmic surgeries. The need for lifelong surveillance underscores the intensive follow-up required to manage complications and maintain prosthetic function.

Psychological and Functional Implications

Patients often face considerable psychological stress owing to the complexity of the surgical journey and the dramatic changes associated with regaining sight after prolonged blindness. Functionally, while OOKP can restore vision, the quality of the restored vision may not match natural vision, influencing patient satisfaction.

Impact on Long-term Success Rates

These complications can influence long-term success rates by necessitating additional surgeries and interventions, which can risk further decline in vision or prosthetic stability. Compared to synthetic alternatives like the Boston KPro, which also face complications like tissue melt and membrane formation, OOKP still offers advantages in cases of severe ocular surface disease but requires more intensive management of its unique risks [2,13].

Patient-Reported Outcomes

Patient-reported outcomes often reflect satisfaction with vision restoration but underscore the burdens of ongoing medical care and the psychological impact of potential complications. The requirement for frequent follow-ups and the psychological burden of managing a complex, lifelong condition can detract from the overall patient experience.

Overall, while OOKP remains an unrivaled option for restoring vision in the most challenging scenarios, its application is tempered by its high complication rate and the requirement for rigorous postoperative care. Comparatively, while other keratoprosthesis systems may have different complication profiles, they may offer less durability in severe disease contexts, highlighting OOKP's specific niche in complex ocular reconstructions. Studies show positive outcomes despite limited data quality. Varying expertise across centers necessitates multicenter prospective validation [18]. Prognosis depends on follow-up and managing complications like retroprosthetic membrane formation [19]. While OOKP restores sight in untreatable cases, its invasiveness and limited long-term data hinder broader adoption [20].

Recent Advances and Future Directions

Recent advancements in OOKP research and clinical practice have focused on refining surgical techniques, enhancing technological support, and exploring new materials to improve patient outcomes. These efforts are aimed at addressing complications, improving biointegration, and expanding the availability and applicability of OOKP as a treatment option for end-stage corneal blindness.

Surgical Technique Refinements

Improvements in surgical techniques have included enhanced precision in the harvesting and preparation of the tooth-bone complex, as well as innovations in the way the optical cylinder is positioned and secured. Implementing more sophisticated imaging technologies has aided surgeons in planning and executing these highly complex procedures with greater accuracy, reducing intraoperative risks.

Technological Adjuncts

Advancements in imaging technologies and materials have played a crucial role in OOKP. The incorporation of real-time imaging during surgery helps in precise placement, while new biocompatible materials are being tested to reduce inflammation and enhance integration. For instance, the use of nanohydroxyapatite coatings on keratoprosthesis models improves biointegration by reducing fibrotic and immune responses [2].

Perioperative Care Improvements

Emphasis on perioperative care has improved outcomes by standardizing protocols that manage potential complications such as infection and inflammation. These protocols include optimized postoperative regimens focused on maintaining ocular health and preventing prosthetic complications over the long term.

Experimental and Translational Research

Research efforts are underway to replace or augment the biological lamina with tissue-engineered or synthetic materials that mimic the biological properties of the tooth-bone structure. These innovations aim to enhance the durability and longevity of the keratoprosthesis, focusing on materials that offer greater resistance to resorption and inflammatory responses.

Challenges in Accessibility, Cost, and Expertise

Despite these advancements, significant challenges remain in terms of accessibility, cost, and the requirement for specialized surgical expertise. The complexity and cost of the procedure limit its availability to a few specialized centers, primarily in developed countries. Training and maintaining a cadre of skilled surgeons remain a barrier to broader implementation.

CONCLUSION

The osteo-odonto keratoprosthesis (OOKP) stands as a revolutionary and invaluable surgical option for restoring vision in patients with end-stage corneal blindness, especially when traditional transplants are not viable. Its unique use of autologous tooth-bone tissue ensures superior biocompatibility and stability, offering significant functional

and psychological benefits. Despite procedural complexity and risks such as glaucoma and lamina resorption, OOKP's long-term outcomes demonstrate substantial visual improvement and quality of life enhancement. Ongoing advances in surgical techniques, materials, and postoperative care promise to further enhance outcomes and accessibility, positioning OOKP as a cornerstone of treatment for severe ocular surface diseases worldwide.

ABSTRACT

Nanotechnology has revolutionized the food industry, offering innovative solutions to enhance food quality, safety, and shelf life. This review explores the diverse applications of nanoparticles across key areas such as food packaging, processing, and safety monitoring, highlighting their transformative impact. Metallic nanoparticles like silver, zinc oxide, and titanium dioxide are widely used in packaging to provide antimicrobial protection, improve barrier properties, and extend the freshness of perishable items. Organic nanoparticles, including nanocellulose and lipid-based structures, contribute to eco-friendly packaging and effective nutrient delivery systems. Intelligent packaging equipped with nanosensors allows real-time monitoring of food freshness and safety, ensuring that products meet quality standards throughout the supply chain. In food processing, nanotechnology has enhanced nutrient bioavailability, improved texture and flavor stability, and reduced the reliance on chemical preservatives through nanoencapsulation techniques. Nanosensors further strengthen food safety by detecting contaminants, pathogens, and spoilage indicators with high sensitivity and precision. These advancements contribute to reduced food waste, improved nutritional value, and greater consumer confidence. However, the integration of nanotechnology into food systems is accompanied by challenges, including the potential migration of nanoparticles into food, environmental impacts of nanomaterial production, and public skepticism regarding their safety. Regulatory frameworks, such as those from EFSA and FDA, are evolving to address these concerns, emphasizing the need for comprehensive risk assessments and sustainable practices. This review highlights the importance of balancing innovation with safety and sustainability. Future research should focus on developing green synthesis methods, standardizing regulatory protocols, and improving public awareness of nanotechnology's benefits. With

continued advancements, nanoparticles hold the potential to address global food security challenges, ensuring safer, healthier, and more sustainable food systems for the future.

Keywords: Nanotechnology, Food Industry, Food Processing, Food Safety, Food Packaging.

INTRODUCTION

Nanotechnology has emerged as a transformative force in the food industry, addressing long-standing challenges related to food packaging, processing, safety, and nutrition. Nanotechnology has significantly advanced food packaging by enhancing the functionality and efficiency of packaging materials. Nanoparticles are widely used to improve properties of packaging, protecting food from external factors such as moisture, gases, and UV radiation. Materials infused with nanoparticles like clay, silver, and zinc oxide provide better mechanical strength and thermal stability, ensuring the integrity of packaged goods during storage and transport [1, 2]. Additionally, antimicrobial nanoparticles prevent microbial contamination, reducing spoilage and extending the shelf life of perishable items [3]. For example, silver and zinc oxide nanoparticles have shown remarkable efficacy in inhibiting the growth of harmful pathogens, making them invaluable in active packaging systems. Beyond protection, nanosensors embedded in smart packaging enable real-time monitoring of food quality. These sensors detect changes in environmental conditions, such as temperature, humidity, and the presence of spoilage-indicating gases, providing actionable insights to maintain product freshness [2, 4]. This combination of antimicrobial properties and intelligent monitoring capabilities ensures food safety throughout the supply chain in food processing, nanotechnology has introduced innovations that improve the texture, flavor, stability, and nutritional profile of food products. Nanoemulsions and nanoliposomes are widely used to encapsulate and deliver bioactive compounds, preserving their stability and enhancing their bioavailability. These systems enable the controlled release of nutrients, flavors, and antioxidants, ensuring that their functional properties are retained throughout the processing and storage phases [4, 5].

Nano-coatings are another significant advancement, applied to food surfaces to protect them from spoilage and contamination. These coatings create a thin, protective layer that maintains freshness and prevents the growth of microorganisms, extending the shelf life of fresh produce and processed foods [6, 7]. Additionally, nanotechnology enables the production of healthier food options by reducing the fat, sugar, or salt content in processed foods without compromising their sensory attributes. This is achieved through the precise manipulation of nanoparticles to enhance flavor, texture, and mouthfeel, creating a more enjoyable eating experience. Nanotechnology has revolutionized food safety and quality monitoring through the development of advanced detection systems. Nanosensors and biosensors, which incorporate nanoparticles, offer unparalleled sensitivity and specificity in detecting pathogens, toxins, allergens, and chemical contaminants. These devices utilize unique properties such as fluorescence quenching and surface plasmon resonance to identify even trace amounts of harmful substances, ensuring the safety of food products [8, 4]. Metallic nanoparticles, such as gold and silver, play a crucial role in these sensors, enabling rapid and reliable detection through colorimetric assays. This allows for real-time monitoring of food quality, enabling manufacturers to address potential safety issues promptly. Moreover, the integration of nanosensors into food packaging provides continuous monitoring capabilities, ensuring that consumers receive safe and high-quality products. Nanoparticles improve the delivery and bioavailability of essential nutrients and bioactive compounds, making them more effective in promoting health and well-being. Encapsulation techniques, such as nanocapsules and nanoliposomes, protect sensitive ingredients like vitamins, minerals, and antioxidants from degradation, ensuring their stability during storage and digestion [9, 10].

These systems allow for the controlled release of nutrients, targeting specific areas of the body to maximize their benefits. Fortified foods, enriched with nanoscale delivery systems, address nutritional deficiencies by providing a precise and efficient means of nutrient intake. For example, iron or zinc nanoparticles can be incorporated into staple foods to combat anemia or micronutrient deficiencies, particularly in regions with limited access to diverse diets [11].

Despite its transformative potential, the use of nanotechnology in the food industry raises significant regulatory and safety concerns. One of the primary issues is the potential migration of nanoparticles from packaging materials into food products. Studies have shown that certain nanoparticles, such as silver and titanium dioxide, can leach into food under specific conditions, posing risks of cytotoxicity and genotoxicity [6, 12]. This has led to widespread debates about the long-term health implications of nanoparticle ingestion and their effects on human physiology. Additionally, the environmental impact of nanoparticles, including their accumulation in soil and water systems, raises concerns about ecological safety and sustainability. To address these challenges, regulatory bodies like the European Food Safety Authority (EFSA) and the United States Food and Drug Administration (FDA) are actively working to establish guidelines and testing protocols for the safe use of nanotechnology in food applications [13]. However, the lack of standardized evaluation methods and comprehensive risk assessments highlights the need for continued research and collaboration among stakeholders.

Types of Nanoparticles Used in the Food Industry (Figure 1).

Nanoparticles have found diverse applications in the food industry, leveraging their unique properties such as high surface area, reactivity, and functional versatility. These characteristics make them ideal for addressing challenges in food safety, packaging, processing, and nutraceutical delivery. Figure 1 shows detailed classification of the types of nanoparticles employed in this field.

Metal and Metal Oxide Nanoparticles

Silver Nanoparticles (AgNPs): Silver nanoparticles are highly regarded for their potent antimicrobial activity, making them a staple in food packaging to prevent microbial contamination and extend shelf life. AgNPs are often embedded into packaging materials to inhibit bacterial growth and protect perishable items. Additionally, they are integrated into nanosensors to enable real-time freshness monitoring, ensuring food quality throughout the supply chain [14, 15].

Titanium Dioxide (TiO_2): Titanium dioxide is widely used for its antibacterial properties and as a whitening agent in food additives. In food packaging, TiO_2 enhances product safety and aesthetic appeal by providing antimicrobial protection and maintaining the visual quality of packaged goods [15, 16].

Zinc Oxide (ZnO): Zinc oxide nanoparticles are another critical component in advanced food packaging materials. Their strong antimicrobial effects help prevent spoilage and contamination, contributing to longer shelf life for a wide range of food products. ZnO nanoparticles are particularly effective in maintaining food integrity during storage [16,17]

Iron Oxide (Fe_3O_4): Iron oxide nanoparticles are employed in magnetic separation technologies and food preservation processes. Leveraging their magnetic properties, Fe_3O_4 nanoparticles facilitate the removal of contaminants and improve the overall efficiency of food preservation methods [17].

Organic Nanoparticles

Protein Nanoparticles: Derived from natural sources such as whey, casein, or plant proteins, protein nanoparticles are highly valued for their biodegradability and biocompatibility. These nanoparticles are used to encapsulate bioactive compounds, enhancing the delivery of functional ingredients in nutraceuticals and functional foods. Their ability to stabilize emulsions and maintain nutrient integrity makes them indispensable in health-focused food products [18].

Lipid-Based Nanoparticles: Lipid nanostructures, including nanoliposomes and nanoemulsions, are commonly utilized for encapsulating vitamins, flavors, and antioxidants. These nanoparticles not only ensure the stability of sensitive compounds but also facilitate their controlled release, thereby improving their functional performance. Lipid nanoparticles are widely employed in enhancing the sensory qualities and nutritional profile of processed foods [19, 20].

Polymeric Nanoparticles

Biopolymeric Nanoparticles: Biopolymeric nanoparticles, synthesized from natural polymers such as chitosan and alginate, represent an eco-friendly alternative in food applications. These nanoparticles are extensively used in active food packaging to provide antimicrobial activity and as carriers for nutrients and bioactive compounds. Their biodegradability and compatibility with food systems make them an ideal choice for sustainable packaging solutions [20, 21].

Nanocarriers and Delivery Systems

Nanocapsules and Nanomicelles: Nanocapsules and nanomicelles are engineered to protect sensitive nutrients and bioactive compounds, significantly enhancing their bioavailability. These systems are particularly beneficial in nutraceuticals and functional foods, where precision in nutrient delivery is critical. Nanocapsules ensure the stability of encapsulated compounds, safeguarding them from environmental degradation [19].

Nanoemulsions: Nanoemulsions are widely employed for delivering hydrophobic bioactives, which are typically challenging to solubilize in aqueous environments. These systems improve the solubility, stability, and efficacy of nutrients, making them a popular choice for enhancing the functional performance of food additives and nutraceuticals [14, 18].

Carbon-Based Nanomaterials

Carbon Nanotubes (CNTs): Carbon nanotubes are known for their exceptional mechanical strength and barrier properties, making them suitable for advanced food packaging applications. These materials provide superior resistance to moisture and gases, ensuring the long-term preservation of food products. However, their use is limited due to regulatory concerns surrounding their potential health and environmental impacts [2].

Nanoparticles in Packaging

Nanotechnology has revolutionized the food packaging industry by introducing advanced materials and techniques to enhance food preservation, quality, and safety. By leveraging the unique properties of nanoparticles, such as high surface area, reactivity, and functional versatility, traditional packaging has evolved into improved, active, and intelligent systems capable of addressing modern challenges in the food industry. These advancements have made nanoparticles a cornerstone in extending shelf life, preventing contamination, and maintaining the nutritional value of food products [22,23]. Nanoparticles used in food packaging can be broadly classified into metallic, organic, polymeric, and carbon-based nanomaterials, each with unique applications.

Metal and Metal Oxide Nanoparticles: Silver nanoparticles (AgNPs) are renowned for their potent antimicrobial properties. They are widely embedded in packaging films to inhibit bacterial growth, safeguard perishable items, and extend shelf life [24, 22]. Zinc oxide (ZnO) and titanium dioxide (TiO_2) nanoparticles are also pivotal in food packaging due to their antibacterial, UV-blocking, and mechanical enhancement properties. ZnO nanoparticles ensure resistance to microbial growth during storage, while TiO_2 not only offers antimicrobial benefits but also functions as an oxygen scavenger and protects food from UV-induced degradation [25, 23]. Iron oxide (Fe_3O_4), with its magnetic properties, is used in food preservation processes to improve the efficiency of contaminant removal [17].

Organic Nanoparticles: Derived from natural sources, nanocellulose and protein nanoparticles are biodegradable and biocompatible, making them ideal for eco-friendly packaging. Nanocellulose improves mechanical strength and barrier properties, effectively protecting food from gases and moisture [26]. Protein nanoparticles, often derived from whey or plant proteins, encapsulate bioactive compounds, enhancing the functional properties of packaging [18].

Carbon Nanotubes (CNTs): CNTs enhance the mechanical strength and antimicrobial functionality of packaging materials. Their ability to integrate into oxygen sensors for modified atmosphere packaging has proven to be a significant innovation, enabling precise monitoring of food storage conditions [2].

Nanoclays: Nanoclays, integrated into packaging films, strengthen their barrier properties against moisture and gases. Their use in biodegradable films provides both functionality and environmental sustainability, making them a popular choice in sustainable packaging initiatives [27]. Nanoparticles have found diverse applications in food packaging systems, revolutionizing how food is preserved and monitored. Nanoparticles applications in food packaging (Figure 2).

Improved Packaging: Nanoparticles enhance the structural integrity of packaging materials. For example, nanoclay-reinforced films exhibit higher tensile strength and lower oxygen transmission rates, ensuring minimal spoilage and extended shelf life of packaged products. The use of these materials helps retain food texture, flavor, and nutritional content for longer durations [11,28]. packaging systems, enhanced with nanoparticles, offer advanced functionalities:

Antimicrobial Action: Metal nanoparticles like AgNPs and ZnO disrupt microbial membranes and DNA, effectively preventing bacterial growth and reducing the reliance on chemical preservatives. This contributes to longer shelf life and safer food [29,24]

Gas Scavenging: Nanoparticles such as TiO_2 and nanoclays control oxygen and ethylene levels in packaging, delaying the ripening process and minimizing spoilage, particularly in fruits and vegetables [22, 23].

Intelligent Packaging: Intelligent packaging systems utilize nanosensors to monitor environmental conditions and food quality in real time. For instance, nanosensors can detect gas emissions such as ethylene or volatile organic compounds, indicating spoilage or changes in freshness. Additionally, time-temperature indicators and freshness markers provide real-time updates to consumers, ensuring product reliability and reducing food waste [30,31]. The integration of nanoparticles in food packaging offers numerous advantages that address critical challenges in food preservation, sustainability, and consumer satisfaction. Nanoparticles revolutionize food packaging by enhancing barrier properties, strengthening material durability, supporting eco-friendly alternatives, and improving consumer trust through intelligent monitoring systems. These advancements not only ensure food safety and quality but also address environmental and societal challenges in the food industry.

Enhanced Barrier Properties: One of the most notable benefits of nanoparticle incorporation in food packaging is the significant improvement in barrier properties. Nanoparticles, such as nanoclays and metal oxides, reduce the permeability of packaging materials to gases, moisture, and UV light. This feature is essential in slowing down food spoilage caused by oxidative reactions and microbial growth. By creating a more robust barrier, nanoparticles help maintain the freshness, texture, and flavor of food products over extended periods, ultimately reducing food waste and contributing to economic savings [32,33].

Mechanical Strength: Nanoparticles like nanoclays also enhance the mechanical strength and flexibility of packaging materials. This improvement ensures that the packaging can withstand the stresses of storage, handling, and transportation without compromising its integrity. Stronger and more durable packaging not only protects food from physical damage but also enhances its usability and reliability across the supply chain [25].

Eco-Friendliness: Sustainability is a pressing concern in modern packaging solutions, and the use of biodegradable nanoparticles like nanocellulose and nanoclays provides a promising alternative to traditional plastic materials. These nanoparticles are derived from renewable resources and are fully compostable, significantly reducing the environmental impact associated with packaging waste. By offering a greener solution, nanoparticle-infused packaging aligns with global initiatives to reduce plastic pollution and support a circular economy [26].

Consumer Benefits: Nanotechnology has also introduced intelligent packaging systems that incorporate nanosensors to monitor food quality and freshness in real time. These systems detect spoilage indicators such as gas emissions or temperature fluctuations, providing consumers with accurate information about the safety and condition of their food. This transparency enhances consumer trust in packaged products and reduces unnecessary food disposal,

promoting more responsible consumption habits [31]. Table 1 highlights the applications of nanoparticles in food packaging, emphasizing their contributions to food safety, quality, and sustainability.

Nanoparticles in Food Safety and Quality Monitoring

Nanotechnology has revolutionized food safety and quality monitoring by introducing highly sensitive and selective detection methods and improving packaging technologies. Table 4.1 provides a overview of how nanoparticles contribute to food safety and quality monitoring. Nanoparticles are integral to developing nanosensors and biosensors that detect pathogens, toxins, allergens, and chemical contaminants with high precision. These sensors utilize properties such as fluorescence quenching and surface plasmon resonance for enhanced sensitivity [34,35,36]. Gold and silver nanoparticles are particularly effective due to their optical and electronic properties, enabling the detection of trace amounts of contaminants [37, 38]. They are widely used in colorimetric assays, ensuring rapid and reliable results in food safety testing [37, 39].

Food Packaging

Nanoparticles such as silver, zinc oxide, and titanium dioxide are incorporated into packaging materials to inhibit microbial growth. This extends the shelf life of food products by preventing spoilage and contamination [40-42]. Nanotechnology has enabled smart packaging systems that monitor environmental conditions and food quality in real-time. These systems often include freshness indicators or RFID-enabled devices that detect changes in temperature, humidity, or the presence of spoilage gases [43-44]

Quality Monitoring

Nano-biosensors allow for the rapid and real-time monitoring of food quality across the supply chain. This includes detecting spoilage markers, such as volatile organic compounds or ethylene gas, ensuring prompt corrective actions [39,45]. The integration of nanomaterials enhances the sensitivity and selectivity of analytical devices, allowing for the detection of contaminants at extremely low concentrations [39,46]. Nanoparticles in Food Safety and Quality Monitoring (Table2).

Nanoparticles in Improving Food Preservation and Shelf Life

Nanoparticles are instrumental in extending the shelf life of food products (figure 3) by preventing spoilage and contamination. Metal and metal oxide nanoparticles, such as silver (AgNPs), zinc oxide (ZnO), and titanium dioxide (TiO_2), exhibit potent antimicrobial properties that inhibit the growth of harmful microorganisms, thus reducing foodborne illnesses and maintaining product freshness [47-48]. These nanoparticles disrupt microbial membranes and cellular processes, effectively neutralizing bacteria and other pathogens that contribute to food spoilage. Nanoencapsulation further enhances food preservation by protecting sensitive bioactive compounds from degradation. This technique involves encapsulating vitamins, antioxidants, and other functional ingredients within nanoparticles, ensuring their stability and controlled release during storage and consumption [49-50]. Nanoencapsulation is particularly effective in maintaining the sensory and nutritional qualities of food, such as flavor, texture, and nutritional content. Additionally, nanoparticles improve the barrier properties of food packaging materials, preventing the ingress of oxygen and moisture, which are primary factors in food spoilage. For instance, TiO_2 and ZnO nanoparticles enhance the impermeability of packaging films, protecting food products from environmental factors that could compromise their quality and shelf life [12,51]. These advancements not only prolong freshness but also minimize food waste by ensuring that products remain safe and consumable for extended periods. The application of nanosensors in food safety has revolutionized the detection of pathogens and contaminants. Nanosensors are capable of identifying minute amounts of harmful microorganisms, such as Escherichia coli and Salmonella, with high sensitivity and specificity. These sensors provide rapid and accurate detection, ensuring timely interventions to prevent the spread of foodborne illnesses [43,52]. Nanotechnology has significantly contributed to improving the nutritional quality of food through enhanced bioavailability and the development of functional foods. Nanoparticles can encapsulate nutrients and supplements, such as vitamins and minerals, ensuring their stability and targeted delivery. This allows the body to absorb these nutrients more efficiently, optimizing their health benefits [53-54]. Functional foods fortified with nanoparticles offer additional

health benefits by delivering bioactive compounds directly to the target site within the body. For example, nanoencapsulation ensures that probiotics, omega-3 fatty acids, and antioxidants remain stable during digestion and are released only when needed, enhancing their efficacy and functionality [7-54]. The integration of nanoparticles into the food industry has resulted in several key advantages. First, nanoparticles improve food preservation and shelf life, reducing waste and ensuring product availability over longer periods. Second, nanosensors enhance food safety by providing rapid, accurate, and cost-effective detection of contaminants and spoilage markers. Third, nutritional enhancement through nanotechnology has led to the development of innovative functional foods that cater to the growing demand for health-focused dietary solutions.

Potential Health Implications of Consuming Food Products Containing Nanoparticles

The incorporation of nanoparticles (NPs) into food products offers numerous functional benefits, but it raises significant health concerns due to their unique physicochemical properties. Current research highlights the following potential health implications:

Gastrointestinal Effects: Nanoparticles primarily interact with the gastrointestinal (GI) tract upon ingestion, potentially disrupting gut homeostasis. Studies indicate that NPs can alter gut microbiota composition and interact with mucus, impairing its protective functions. For example, silver (Ag) and titanium dioxide (TiO_2) nanoparticles have been linked to gut inflammation and reduced barrier integrity [55-56].

Cellular and Molecular Toxicity: Nanoparticles like silicon dioxide (SiO_2) and tricalcium phosphate (E341) have demonstrated cytotoxic effects, including reduced cell viability, mitochondrial dysfunction, and increased production of reactive oxygen species (ROS). ROS-induced oxidative stress can upregulate apoptosis-related genes, leading to cellular damage [57-58].

Systemic Toxicity: Due to their small size, nanoparticles can traverse biological barriers, entering systemic circulation and accumulating in organs. Chronic exposure has been associated with hepatotoxicity, nephrotoxicity, immunotoxicity, and endocrine disruption. Long-term health risks, such as carcinogenesis and neurodegenerative conditions, remain areas of concern [59-60].

Association with Chronic Diseases: Emerging evidence links chronic exposure to nanoparticles with diseases like Alzheimer's, Parkinson's, and Crohn's disease. These effects may arise from their ability to induce systemic inflammation and oxidative stress [55-56].

Environmental Impacts of Using Nanoparticles in Food Production Processes

The application of nanoparticles (NPs) in food production processes presents numerous benefits but also significant environmental challenges. Below is a comprehensive analysis of these impacts.

Potential Benefits

Nanoparticles act as delivery systems for essential nutrients, improving crop yield and preventing soil degradation. Nano-fertilizers and nano-pesticides provide targeted delivery, reducing the overall quantity of agrochemicals needed while minimizing environmental residues [61-62]. Nano-enabled agrochemicals offer controlled release mechanisms, increasing the efficacy of fertilizers and pesticides. These properties reduce run-off into water bodies, limit environmental contamination, and promote sustainable farming practices [63-64]. NPs enhance food products by improving their texture, nutritional content, and shelf life. They also prevent microbial contamination in packaging, reducing food waste and spoilage [65-66].

Environmental Concerns

The release of engineered nanoparticles into ecosystems can lead to cytotoxic, genotoxic, and oxidative stress effects on aquatic and terrestrial organisms. For instance, metal oxide nanoparticles have been linked to disruptions in the physiological processes of plants and fish [67-68]. NPs can enter the food chain through agriculture and packaging,

leading to bioaccumulation in plants, animals, and humans. This raises concerns about long-term ecological toxicity and effects on growth, reproduction, and survival of organisms [69-70]. NP residues in agricultural soil may alter nutrient mobility, disrupt microbial communities, and reduce soil quality. Water bodies exposed to nanoparticle runoff face risks of contamination, affecting aquatic ecosystems and food chains [71-72]. Consumption of food products containing NPs or water contaminated with NP residues poses risks of DNA damage, organ toxicity, and chronic diseases. This highlights the urgent need for safe usage guidelines [73-74].

Challenges and Safety Concerns

Nanotechnology has revolutionized food quality and safety, but its adoption comes with significant challenges and safety concerns that require attention and action.

Toxicity and Migration: One of the primary concerns is the potential migration of nanoparticles from packaging materials into food products. For instance, silver nanoparticles, while highly effective as antimicrobial agents, have been linked to health risks such as genotoxicity and neurotoxicity if they leach into food. Similarly, the high reactivity of metal oxide nanoparticles, like zinc oxide (ZnO) and titanium dioxide (TiO_2), can lead to oxidative stress and cellular damage in living organisms. Comprehensive safety evaluations and toxicological studies are critical to mitigating these risks and ensuring the safe application of nanoparticles in food systems [23, 75].

Regulatory Oversight: Regulatory frameworks play a pivotal role in the responsible implementation of nanotechnology in the food industry. Agencies such as the European Food Safety Authority (EFSA) and the United States Food and Drug Administration (FDA) are actively working to establish guidelines for evaluating the environmental fate, bioavailability, and toxicity of nanoparticles. However, the lack of standardized testing protocols and long-term data on nanoparticle behavior in food matrices presents a significant challenge [76].

Environmental Concerns: The production, usage, and disposal of nanomaterials raise critical environmental concerns. Nanoparticle synthesis often involves chemical processes that may contribute to pollution and resource depletion. Additionally, the disposal of nanoparticle-containing materials poses potential risks to ecosystems. The unintended release of nanoparticles into soil and water can disrupt microbial communities and harm aquatic organisms, emphasizing the need for comprehensive life cycle analyses and sustainable production practices [29, 33].

Commercialization Barriers: The cost and scalability of nanoparticle production present significant barriers to widespread adoption in the food industry. Developing cost-effective manufacturing methods and integrating nanotechnology into existing food systems remain challenges, particularly for small and medium-sized enterprises. Streamlining production processes and fostering collaborations between research institutions and industry stakeholders can help overcome these barriers [5].

Consumer Perception: Public skepticism and misconceptions about the safety of nanotechnology in food products pose hurdles to its acceptance. Concerns about potential health risks, combined with limited consumer understanding of nanotechnology's benefits, necessitate transparent communication and educational initiatives. Highlighting the safety assessments, regulatory compliance, and benefits of nanotechnology is essential to gaining consumer trust [41, 76].

Future Directions

The application of nanoparticles in the food industry holds immense potential for innovation, yet several avenues require exploration and refinement to maximize their impact. Future research should prioritize developing safer and eco-friendly nanoparticles through green synthesis methods, such as microbial or plant-based processes, to minimize environmental and health risks [64, 77]. These sustainable approaches can reduce the ecological footprint of nanoparticle production and address concerns about toxicological impacts [23, 33].

Enhancing the scalability and cost-effectiveness of nanoparticle integration into food systems is another critical direction. This includes optimizing production processes to make nanotechnology accessible to small and medium-sized enterprises, ensuring broader industry adoption [29, 5]. Additionally, standardized testing protocols and regulatory frameworks are essential for evaluating nanoparticle safety and efficacy across diverse food applications [45, 76]. Collaboration between regulatory agencies, industry stakeholders, and academic researchers will be pivotal in establishing these standards. The incorporation of smart and active packaging systems with advanced nanosensors can be further expanded to provide real-time data on food quality, freshness, and safety [22]. These innovations can help reduce food waste and improve supply chain transparency. Finally, public education and awareness campaigns are necessary to address consumer concerns, emphasizing the benefits and safety of nanoparticles in food products [41]. Together, these efforts can ensure the responsible and sustainable use of nanotechnology in the food industry.

CONCLUSION

Nanotechnology has emerged as a transformative force in the food industry, offering innovative solutions to improve food quality, safety, and shelf life. Through the integration of nanoparticles into food packaging, processing, and quality monitoring systems, significant advancements have been achieved. Nanoparticles enhance barrier properties, inhibit microbial contamination, and provide real-time monitoring through nanosensors, ensuring food safety from production to consumption. In food packaging, nanoparticles such as silver, zinc oxide, and titanium dioxide have revolutionized preservation by reducing spoilage and contamination while maintaining the nutritional and sensory attributes of food. Intelligent packaging systems equipped with nanosensors enable real-time freshness monitoring and ensure that consumers receive high-quality products. In processing, nanoencapsulation technologies have improved nutrient bioavailability, extended shelf life, and reduced the need for chemical preservatives, contributing to healthier and more sustainable food options. Despite these benefits, the application of nanotechnology in the food industry is not without challenges. Concerns surrounding nanoparticle migration, potential toxicity, and environmental impacts underline the need for rigorous safety evaluations and sustainable practices. Regulatory bodies like the EFSA and FDA are working to establish comprehensive guidelines to address these issues. Further research is essential to develop eco-friendly nanoparticles, optimize scalability, and improve consumer trust through transparency and education. The potential of nanotechnology to address global food security challenges is immense. As innovation continues, a balanced approach that prioritizes safety, sustainability, and effectiveness will ensure the responsible integration of nanotechnology, fostering a future where food systems are both advanced and sustainable.

Table 1: The applications of nanoparticles in food packaging

Category	Application	Description	References
Metal and Metal Oxide Nanoparticles	Antimicrobial Action	Silver (AgNPs) and zinc oxide (ZnO) nanoparticles prevent bacterial growth, safeguarding perishable items and extending shelf life.	Todorova and Lasheva, 2017 [24]; Ashfaq *et al*., 2022 [22].
	UV Protection and Gas Scavenging	Titanium dioxide (TiO_2) blocks UV light, scavenges oxygen, and enhances antimicrobial properties, while ZnO protects from microbial growth.	Alizadeh Sani *et al*., 2022[25]; Santos *et al*., 2024 [23].
	Magnetic Applications	Iron oxide (Fe_3O_4) nanoparticles are used in magnetic separation and food preservation to remove contaminants efficiently.	Jagadish *et al*., 2018[17].
Organic Nanoparticles	Mechanical Strength and Barrier Properties	Nanocellulose improves structural strength and gas/moisture barriers, providing eco-friendly packaging solutions.	Singh *et al*., 2024[26].
	Encapsulation	Protein nanoparticles encapsulate bioactive compounds, enhancing the functional properties of packaging.	Gao *et al*., 2023 [18]
Carbon-Based Nanomaterials	Enhanced Mechanical Strength and Sensors	Carbon nanotubes (CNTs) enhance packaging durability and integrate oxygen sensors for modified atmosphere packaging.	Thirumalai *et al*., 2023 [2]
Nanoclays	Barrier Enhancement	Nanoclays strengthen packaging films by improving resistance to moisture and gases, offering environmental sustainability.	Sharma and Dhanjal, 2016 [27].
Improved Packaging	Structural Integrity	Nanoclay-reinforced films offer high tensile strength and low oxygen transmission rates, reducing spoilage and extending shelf life.	Almeida *et al*., 2015 [11]; Faudzi *et al*., 2020[28].
Active Packaging	Antimicrobial Properties	Metal nanoparticles like AgNPs and ZnO disrupt microbial membranes, enhancing food safety and shelf life.	Buledi *et al*., 2024[29]; Todorova and Lasheva, 2017[24].
	Gas Scavenging	Nanoparticles such as TiO_2 and nanoclays regulate oxygen and ethylene levels, delaying ripening and spoilage in fresh produce.	Ashfaq *et al*., 2022 [22]; Santos *et al*., 2024 [23].

Intelligent Packaging	Real-Time Monitoring	Nanosensors in packaging detect gas emissions and spoilage indicators, ensuring product reliability and reducing food waste.	Aswathanarayan and Vittal, 2015 [30]. Shams *et al*., 2021[31].
Advantages	Enhanced Barrier Properties	Nanoparticles reduce permeability to gases, moisture, and UV light, prolonging shelf life and maintaining food quality.	Nirmal *et al*., 2024[32]; Sabat *et al*., 2024[33].
	Mechanical Strength	Nanoparticles such as nanoclays enhance durability and flexibility, ensuring protection during storage and transportation.	Alizadeh Sani *et al*., 2022[25].
	Eco-Friendliness	Biodegradable nanoparticles like nanocellulose and nanoclays provide sustainable alternatives to conventional packaging.	Singh *et al*., 2024[26].
	Consumer Benefits	Intelligent packaging systems help consumers assess food freshness and safety, reducing waste and improving trust.	Shams *et al*., 2021[31].

Table 2: Nanoparticles in Food Safety and Quality Monitoring

Application Area	Description	Example/Details
Detection of Contaminants	Nanoparticles enhance the sensitivity and selectivity of nanosensors and biosensors for identifying harmful substances.	- Gold and silver nanoparticles used in colorimetric assays for detecting trace contaminants [37]. - Nanosensors detect pathogens, toxins, allergens, and chemical contaminants [34,35].
Food Packaging	Nanoparticles integrated into packaging materials inhibit microbial growth and extend shelf life.	- Silver, zinc oxide, and titanium dioxide nanoparticles prevent spoilage and contamination [40, 42]. - Smart packaging systems monitor temperature, humidity, and spoilage gases with RFID and freshness indicators [43].
Quality Monitoring	Nano-biosensors provide real-time monitoring of food quality across the supply chain.	-Detects spoilage markers like volatile organic compounds and ethylene gas [39,45]. - Enhances the sensitivity of analytical devices for low-concentration contaminants[46].

ABSTRACT

Since type 2 diabetes mellitus (T2DM) necessitates lifetime medical care, some patients look for alternative methods because they are worried about the adverse effects of traditional therapy. A 39-year-old man with poorly managed type 2 diabetes (HbA1c 12.5%) chose to stop using insulin on his own initiative and pursue only Ayurvedic treatment. He was treated with traditional Ayurvedic formulations such as Chandraprabha Vati, TriphalaVati, Madhumeha Kusumakara Rasa, and a standardized polyherbal formulation, along with customized dietary and lifestyle changes, comprehensive informed consent and the implementation of a safety procedure.Periodic blood glucose checks and established procedures for an emergency return to standard treatment were part of the ongoing monitoring. HbA1c dropped from 12.5% to 6.8%, postprandial glucose from 454 to 209 mg/dL, and fasting blood glucose from 261 to 129 mg/dL throughout a nine-month period. The symptoms of traditional diabetes went away entirely without any negative consequences. After insulin discontinuation, this case illustrates the

possible efficacy of structured Ayurvedic treatment for type 2 diabetes. However, before wider clinical use, bigger controlled trials are necessary to verify safety and efficacy.

Keywords: Madhumeha Kusumakar, insulin withdrawal, Madhumeha, case report, type 2 diabetes mellitus

INTRODUCTION

Type 2 diabetes mellitus (T2DM) affects about 537 million [1] people globally as of 2024, and estimates suggest that number will rise to almost 783 million [2] by 2045. India has the second-highest incidence [3] of diabetes in the world, with almost 74 million individuals dealing with this illness. Even though conventional medicines like insulin, metformin, and other antidiabetic medications are still the gold standard because to their demonstrated safety and effectiveness, long-term use can be problematic due to side effects, progressive pancreatic beta-cell degeneration, and issues with treatment adherence. According to recent systematic reviews, 15–30% of patients with type 2 diabetes are dissatisfied [4] with their therapy, which prompts some to look into complementary and alternative medicine [5-6]. High-quality data for standalone Ayurvedic treatment is still lacking, especially after insulin cessation, despite the fact that numerous research have examined Ayurvedic interventions [7] as supplemental therapies to traditional diabetes management [8]. This case study details a patient who, under strict safety supervision, stopped taking insulin on their own and improved their glycemic control by using just Ayurvedic treatment.

CASE PRESENTATION

Patient Information

A married man with poorly managed type 2 diabetes who was 39 years old, nonsmoking, and nonalcoholic arrived at an Ayurvedic clinic on April 5, 2024. He mentioned the typical symptoms of diabetes, such as weariness, blurred vision, polyuria, polydipsia, polyphagia, and recurrent UTIs. Anger and depression related to the burden of a chronic illness were additional psychological symptoms. The patient's body habitus was medium, with a sedentary occupation, irregular eating patterns that included a lot of processed foods, and little exercise. Maternal hypertension and paternal diabetes were significantly influenced by family history.

Medical History

Six months before the presentation, T2DM was diagnosed and was first treated with 500 mg of metformin twice a day. Treatment was raised to premixed insulin 30/70 (20 units twice daily) due to insufficient glycaemic control. Symptoms continued even after adherence was verified by glucose logs and prescription records. Three weeks before the presentation, the patient voluntarily stopped taking insulin and sought only Ayurvedic treatment.

Clinical Outcomes

Physical Inspection: Vital Signs: BMI 26.8 kg/m2, heart rate 88/min, respiration rate 20/min, oxygen saturation 96%, blood pressure 140/90 mmHg,
General examination: alert, focused, clinically stable, slightly dehydrated;
Systemic examination: no noteworthy neurological, cardiovascular, or respiratory findings

Ayurvedic Assessment

Dashavidha Pariksha (Tenfold Examination)
Prakriti (Constitutional type): Pitta Pradhan Kaphanubandhi
Vikriti (Current imbalance): Kaphapradhan Vata-Anubandhi
Sara (Tissue quality): Madhyam (Medium)
Samhanan (Structural strength): Madhyam (Medium)

Pramana (Body proportion): Madhyam (Medium)
Satmya (Adaptability): Hina (Low)
Satva (Mental strength): Madhyam (Medium)
Ahara Shakti (Digestive capacity): Madhyam (Medium)
Vyayama Shakti (Physical endurance): Hina (Low)
Vaya (Age group): Madhyam (Medium)

Ashtavidha Pariksha (Eightfold Examination)
Nadi (Pulse): Pitta Pradhan Kaphanubandhi
Mala (Stool): 2-3 times daily, sticky consistency
Mutra (Urine): 10-12 times daily
Jivha (Tongue): Saam (coated)
Shabda (Voice): Prakrita (normal)
Sparsha (Touch): Prakrita (normal)
Drika (Vision): Prakrita (normal)
Akruti (Appearance): Madhyam (medium)

Diagnostic Assessment

Baseline Laboratory Investigations: HbA1c: 12.5%; fasting blood glucose: 261 mg/dL; postprandial blood glucose: 454 mg/dL Triglycerides: 184 mg/dL, Total cholesterol: 198 mg/dL Creatinine in serum: 1.0 mg/dL; Ketones in urine: Negative. Clinical evaluation showed that Mutravaha Srotas had Kapha-Meda vitiation, as evidenced by the traditional Madhumeha characteristics [9-10] of Prabhuta Mutratva (polyuria), Pipasa (excessive thirst), Tandra (lethargy), and Angasada (weariness) [11]. By combining scientific results with Ayurvedic symptoms, Madhumeha—a form of Prameha that necessitates comprehensive treatment—was diagnosed.

Safety Procedures and Informed Consent

A thorough procedure for informed consent addressed

- The risks of insulin withdrawal;
- The course and complications of uncontrolled diabetes;
- The available conventional treatment alternatives;
- The monitoring protocols and emergency management procedures;
- The criteria for returning to conventional therapy
- The lack of evidence supporting standalone Ayurvedic management were all covered in a comprehensive informed consent procedure.
- Written consent was required for both treatment and publication purposes.

Emergency Management Plan

- Hospital admission procedures for acute complications
- Patient education regarding diabetes emergency warning indicators
- 24-hour physician contact availability Protocol for Therapeutic Intervention

Therapeutic Intervention

The patient received exclusive Ayurvedic management aimed at reducing glycemic load, correcting metabolic imbalance, and alleviating Madhumeha symptoms.

Pharmacological Interventions

Ayurvedic Medicines Used for the Management of Type 2 Diabetes Mellitus (Table 1).

Polyherbal Formulation Composition: Equal proportions of *Paṭola* (*Trichosanthes dioica*), *Guḍmara* (*Gymnema sylvestre*), *Karavellaka* (*Momordica charantia*), *Nimba* (*Azadirachta indica*), *Amalaki* (*Emblica officinalis*), *Jinsi* (*Salacia reticulata*), *Vijayasara* (*Pterocarpus marsupium*), *Haridra* (*Curcuma longa*), and *Saptarangi* (*Salacia chinensis*). All medications were procured from GMP-certified Ayurvedic manufacturers to ensure quality and safety standards.

Non-pharmacological Interventions

- Constitution-based dietary plan to regulate metabolism and minimize postprandial glucose fluctuations
- Regular exercise, 30 minutes of brisk walking and several yoga postures
- Lifestyle modifications to enhance metabolic balance and reduce stress

Follow-up Timeline Showing Clinical Outcomes during Ayurvedic Intervention (Table 2).

Follow-Up and Outcomes

The patient was monitored over a nine-month period from April through December 2024, during which substantial improvements in glycemic control were observed. Primary metabolic parameters demonstrated remarkable enhancement, with fasting blood glucose levels declining from an initial reading of 261 mg/dL to 129 mg/dL by the study's conclusion. Similarly, postprandial glucose concentrations showed significant reduction from 454 mg/dL to 209 mg/dL over the same timeframe. The most clinically relevant improvement was observed in long-term glycemic control, as evidenced by the reduction in HbA1c levels from 12.5% to 6.8%, indicating a transition from poor to acceptable diabetic control. Beyond laboratory parameters, the patient experienced progressive resolution of clinical symptoms characteristic of uncontrolled diabetes. By September 2024, approximately five months into treatment, both polyuria and polydipsia had completely resolved, marking a significant milestone in symptom management. Concurrent improvements included sustained enhancement in energy levels and overall quality of life, which the patient reported consistently throughout the monitoring period. Treatment tolerability proved exceptional, with no documented adverse events or side effects requiring intervention or modification of the therapeutic regimen. Patient compliance remained consistently high throughout the study duration, validated through multiple assessment approaches including medication review, symptom tracking, and correlation with clinical response patterns. Systematic adverse event inquiries and physical examinations at each visit confirmed the safety profile of the Ayurvedic intervention. No treatment modifications or discontinuations were required.

DISCUSSION

This case exemplifies the application of classical Ayurvedic principles in managing severe hyperglycemia following insulin withdrawal. The therapeutic success achieved through exclusive Ayurvedic intervention demonstrates the potential effectiveness of traditional medicine [12] approaches in T2DM management. According to Ayurvedic principles, Prameha represents a metabolic disorder with hereditary predisposition, predominantly involving Kapha dosha, Meda dhatu, and Mutravaha srotas [13]. The patient's sedentary lifestyle, irregular dietary habits, and processed food intake aggravated Kapha, increased kleda (fluid accumulation), and caused dhatu saithilya (tissue laxity) [14]. This pathological [15] cascade results in kleda accumulation, dhatu saithilya, Agni-mandya (digestive fire impairment), srotorodha (channel obstruction), and Oja-kshaya (vital essence depletion) [16]. Chandraprabha Vati [17] known for Vata-Kapha shamana activity across all dhatus and srotas. Its Laghu and Ruksha properties facilitate Bahudrava Shleshma shodhana and kleda reduction. Bioactive components including Shilajatu and Guggulu contribute virukshana, chedana, and rasayana actions, supporting metabolic regulation and homeostasis restoration. Triphala Vati [18] demonstrates significant hypoglycemic activity in experimental insulin resistance models and clinical studies. Its antioxidant and neuroprotective properties, along with its kledahara, rasayana, and Kaphapitta hara features, help glycaemic control [19] and the prevention of diabetic problems. Madhumeh Kusumakar Rasa, [20] exhibits significant antidiabetic activity. It reduces fasting blood glucose and insulin, improves OGTT performance, and enhances insulin sensitivity indices (HOMA-IR, HOMA-IS, FGIR), with efficacy comparable to or exceeding metformin. The formulation's actions include enhanced peripheral glucose uptake, reduced hepatic gluconeogenesis, and stimulation of insulin secretion. MKR also improves lipid metabolism by lowering triglycerides, LDL, VLDL, and total cholesterol, while elevating HDL, likely via restored insulin signaling and modulation of lipase activities. Histopathology validates protective effects on liver, kidney, and pancreas. These multimodal benefits position MKR as a promising alternative or adjunct therapy for insulin resistance–associated type 2 diabetes mellitus. The customized polyherbal formulation combines botanicals with complementary antidiabetic mechanisms [21]. Key components include *Gymnema sylvestre* (gymnemic acids for β-cell regeneration) [22], *Momordica charantia* (charantin

with insulin-mimetic activity) [23], *Pterocarpus marsupium* (pterostilbene for α-glucosidase inhibition) [24], and *Curcuma longa* (curcumin for insulin sensitization). *Azadirachta indica* offers hepatoprotective nimbin and azadirachtin compounds with documented glucose-lowering effects, while *Trichosanthes dioica* provides dietary fiber and bioactive compounds supporting gastrointestinal glucose regulation Salacia species provide salacinol compounds for carbohydrate enzyme inhibition, while *Emblica officinalis* contributes antioxidant protection for pancreatic cells. From an Ayurvedic perspective, the combination exhibits Kapha-Medohara properties, supporting metabolic fire (Agni) enhancement and toxin (Ama) elimination in Madhumeha pathophysiology. The equal-parts ratio ensures balanced therapeutic effects, though standardized active compound concentrations remain essential for reproducible outcomes. The marked HbA1c reduction from 12.5% to 6.8% within nine months represents clinically meaningful glycemic control achieved without conventional therapy. This outcome suggests potential effectiveness of individualized Ayurvedic management for T2DM, particularly in patients with treatment dissatisfaction or contraindications to conventional therapy.

LIMITATIONS

- This single-case report has inherent limitations including
- Absence of control group or randomized design
- Limited generalizability due to individual patient factors
- No C-peptide, insulin levels, or OGTT were performed, limiting mechanistic insight.
- Relatively recent diabetes diagnosis (6 months) potentially contributing to treatment responsiveness
- Need for detailed metabolic profiling and longer follow-up periods Safety Considerations Voluntary insulin discontinuation represents a high-risk clinical scenario requiring intensive monitoring and emergency protocols. Such approaches should only be considered under expert supervision with appropriate safety measures and patient selection criteria.

CONCLUSION

This case demonstrates the potential effectiveness of individualized Ayurvedic management in T2DM following insulin withdrawal, achieving significant glycemic and symptomatic improvements without adverse events. However, these findings require validation through larger controlled trials before integration into mainstream diabetes management protocols.

FUTURE RESEARCH SHOULD FOCUS ON

- Randomized controlled trials comparing Ayurvedic interventions with standard care
- Standardization of herbal formulations and dosing protocols
- Long-term safety and efficacy assessment
- Identification of patient selection criteria for alternative therapy approaches

Patient Perspective

"I was initially apprehensive about discontinuing insulin therapy, but comprehensive monitoring and gradual improvement gave me confidence in the Ayurvedic approach. The medicines were well tolerated, and I appreciated the focus on diet and lifestyle along with medications. The progressive reduction in my symptoms significantly improved my quality of life. I continue to follow the prescribed regimen and maintain regular monitoring as advised."

ABSTRACT

The fast adoption of Artificial Intelligence (AI) in learning institutions has revolutionised English language learning (ELL) in the global domain. The proposed study aims at examining how AI-enhanced tools, including adaptive learning platforms, speech recognition applications, and automated writing assistant, affect the English proficiency of senior secondary students in Hyderabad, India. With broad variances in types of schools, curriculum (CBSE, ICSE, and State Boards), and technological infrastructure, the study looks at how the AI usage can narrow down the learning gaps existent. A designed quantitative questionnaire was distributed among 248 students (two private and two government schools) gathering responses about the usage of tools, learner motivation, type of school and board affiliation. The correlation between AI engagement and language proficiency was analysed using statistical tools, specifically Pearson correlation, independent t-tests, ANOVA, and multiple regression. The findings describe that there exists a positive relationship between the frequent use of AI and positive gains in vocabulary, speaking, and writing abilities. Moreover, the motivational elements (real time feedback, gamification of the content) played a significant role in increasing the interest and engagement in learning especially among the government school students. Curriculum-specific alignments are also evident in the study and the recommendations indicate that board-wise adoption of AI tools can be used to make learning effective. Through an urban, yet varied setting, the study offers empirical data confirming the involvement of AI-based interventions in Indian secondary schools. It ends with policy recommendations at the level of scaling, inclusivity, and pedagogical effectiveness of AI integration to enhance English language proficiency along socio-economic and institutional lines.

Keywords: Artificial Intelligence in Education, English Language Learning (ELL), Secondary School Students, AI-Enabled Language Tools, Language Proficiency and Motivation

INTRODUCTION

Artificial Intelligence (AI) has been a game changer in the learning environment, particularly in the English language learning (ELL) in the secondary level in the recent years. Students are also receiving a more personalized and responsive type of education with the help of intelligent tutoring systems, AI-based chatbots, mobile learning applications, speech recognition software, and automated writing feedback systems (Wahyuni, Putro, and Efendi 74; Kristiawan, Bashar, and Pradana 102). Such innovations do not only complement traditional teaching but also embrace self-paced learning and adaptive learning which is proven to enhance engagement, retention, and language proficiency among learners (Cui *et al*. 58; Fathi and Khodabakhsh 243). A bibliometric analysis conducted by Wahyuni, Putro, and Efendi demonstrates that the world is seeing a steep rise in the application of AI in ELL between 2015 and 2023 due to its ability to provide personalization of language training depending on the profile of the learner (Wahyuni, Putro, and Efendi 76). Kristiawan, Bashar, and Pradana also state that AI technologies enhance speaking and writing skills as they can give instant and constructive feedback to the students immediately, particularly in large classrooms where it is harder to pay attention to each student individually (Kristiawan, Bashar, and Pradana 105). The results of Cui *et al*. show that secondary school students in Beijing who followed an AI-based grammar and vocabulary platform had a 21 percent higher average proficiency score than students in regular classrooms (Cui *et al*. 62). Evidence on this is however scant in the Indian context and especially in multicultural urban cities like Hyderabad where there exist broad differences in socio-economic status, school infrastructure, school curriculum boards (CBSE, ICSE and State Boards). In the context of Hyderabad, some AI initiatives have been currently piloted to solve the resource gap in government schools. IIIT Hyderabad has come up with a speech evaluation software named as SpeakAssist which is aimed at providing phoneme level pronunciation feedback to students who do not have fluent English teachers (New Indian Express; Deccan Chronicle).

A 6-month pilot in Moinabad Mandal indicated that Class 10 students who used the tool scored 31 per cent higher on oral fluency (IIITH). In 2023, the Telangana government, in cooperation with a local EdTech startup LinguaLeap, installed AI labs in 25 municipal schools in the city ("Hyderabad School Introduces AI"). However, the majority of scholarly research in India has been conducted on disjointed treatments like vocabulary acquisition. A six-week research project carried out by Chingakham and Tamuk in Arunachal Pradesh indicated that the vocabulary retention rates of Class 12 students who were subjected to AI flashcard applications showed statistically relevant improvement (Chingakham and Tamuk 88). On the global level, Fathi and Khodabakhsh implement a quasi-experimental study in Iran and reveal that AI-powered essay scoring systems can increase the accuracy of student writing by 28 percent and save teachers 40 percent of time on corrections (Fathi and Khodabakhsh 247). In 2023, a report published by Nature described how mobile AI-assisted writing tools were used in Indonesia to improve academic writing scores in English by almost one band level (Nature 54). The success of AI in education is also impossible to comprehend without taking into consideration psychological factors, including learner motivation, self-efficacy, and cognitive engagement (Ebadi and Amini 311; Liang *et al*. 207; Jin *et al*. 293). The capability of AI in offering experiences that are gamified, dynamically challenging, and offering individualized achievement routes enhance the intrinsic motivation and prolonged focus of learners (Wang and Lin 190). Nonetheless, there is virtually no research anywhere in the world, leave alone India, which has focussed on senior secondary school students (age 1618), a group that occupies a unique positioning point between national board exams and college entry-level competition. The paper seeks to fill that gap through a quantitative survey of 248 senior secondary students (Classes 11 and 12) in four schools in Hyderabad, two government schools and two private schools.

It explores the relationship between the AI tool frequency of use and levels of English language proficiency, other variables being the type of school, board, and motivational indices. The statistical tools employed are Pearson correlation, ANOVA, independent samples t-tests, logistic regression, and multiple regression analyses: the significant level was 0.05 (Wahyuni, Putro, and Efendi 78). The study will offer location-specific knowledge by concentrating on a demographically varied city, Hyderabad, and therefore, it will bring context-specific information on how AI can be used to democratise English education across social-economic and institutional boundaries.

Although it is consistent with the world literature, the study acknowledges the specificity of the Indian educational ecosystem and analyzes the possibility of AI interventions at scale, inclusivity, and effectiveness. Its results will be used to inform policymakers, EdTech builders, and teachers to build AI-powered technologies that are pedagogically sound, curriculum-mapped, and socially equitable.

Statement of the problem

Artificial intelligence (AI) is a strong educational tool that has changed language learning in recent years and has a potential to change it even more. Nevertheless, there is a lack of research on the effectiveness of the AI-based tools in enhancing English language proficiency among Indian senior secondary students. A large number of students particularly in the government schools and in the regional boards do not have proper access to personalised modes of learning and in many cases have difficulty in English proficiency. Although AI applications boast of providing adaptive and interactive learning processes, less is known about their explicit effects on language performance, motivation, and engagement of the students concerned. Hence, it is urgently needed to check whether the application of AI-based tools has the actual positive effect on the English language proficiency of students and whether it differs in relation to school types and academic boards.

Significance of the study

The proposed research is valuable because it will assess the effectiveness of AI-based tool use in improving the English language competency among senior secondary school learners in Hyderabad. English is considered very important in higher education, competitive exams and jobs in a multilingual country such as India. Understanding where AI makes a difference in this field can assist teachers, decision-makers, and organizations to implement new approaches to enhance the achievement of learning English. Through the comparison, the study would give an understanding of the digital divide and academic equity through the performances in the private and government schools, and various educational boards. Curriculum planners and teachers can use the findings to incorporate AI tools in the classroom instructions, which will eventually help promote student engagement, motivation, and academic achievement in learning the English language.

REVIEW OF RELATED LITERATURE

Chingakham and Tamuk (2023) conducted a study on AI-enabled vocabulary retention among Class 12 students in Arunachal Pradesh. Over a six-week period, students used AI flashcard applications designed to reinforce English vocabulary through spaced repetition and pronunciation feedback. The results showed significant improvement in vocabulary acquisition and retention, particularly among students from government schools with limited teaching resources. This study highlights the practical impact of AI tools in remote Indian regions where traditional language teaching methods fall short, proving the efficacy of technology-driven vocabulary instruction in enhancing outcomes (Chingakham and Tamuk 88).

Cui *et al*. (2023) evaluated the effectiveness of AI-based adaptive learning in improving English as a Foreign Language (EFL) performance among Chinese secondary school students. Their study employed a comparison group design, showing that learners using AI platforms achieved better grammar, comprehension, and writing scores than those in traditional classrooms. The adaptive algorithms adjusted content difficulty based on learner performance, encouraging active engagement. This research affirms the role of AI in personalising instruction, thereby boosting language learning in high-school settings. Its relevance to Indian urban classrooms remains high, given similar exam-oriented learning structures (Cui *et al*. 62).

Deccan Chronicle (2024) reported on IIIT Hyderabad's launch of a speech assessment tool aimed at improving English pronunciation among rural school children. Named "SpeakAssist," the tool gives phoneme-level feedback to users, allowing real-time corrections in accent and articulation. The initiative addresses a major problem in government schools—English teachers with limited fluency—and helps reduce dependency on human instruction.

By promoting pronunciation self-correction, the tool bridges linguistic gaps and democratizes learning. The article underscores how homegrown AI tools are being tailored to India's diverse linguistic landscape, offering scalable models for under-resourced educational contexts ("IIIT Hyderabad Develops…").

Ebadi and Amini (2023) explored learner engagement and motivation in AI-mediated language learning environments. Their study, focusing on high school ESL learners, revealed that AI-driven platforms enhanced both behavioural and emotional engagement. Features like immediate feedback, gamified tasks, and interactive visuals increased participation and interest. The authors suggest that AI fosters autonomy and self-regulation, essential qualities for academic success. Their findings are particularly useful for Indian classrooms, where student motivation can be a challenge due to rigid pedagogy. The study supports the integration of interactive AI elements in the secondary curriculum to boost learner involvement (Ebadi and Amini 311).

Fathi and Khodabakhsh (2024) performed a quasi-experimental study on how AI-powered writing assessment tools improve academic performance in ESL writing. Conducted among high school learners, the study showed a 28% improvement in writing quality and coherence, with reduced teacher workload. The AI system provided automatic suggestions on grammar, structure, and vocabulary, enhancing learner autonomy. The authors argue that such tools not only support learners but also assist teachers in time-constrained environments. This model could prove highly effective in Indian senior secondary classrooms where English essay writing remains a core part of assessments (Fathi and Khodabakhsh 247).

IIITH (2024) released an official update regarding the implementation of "SpeakAssist," an AI tool developed to enhance spoken English skills in Telangana's government schools. Deployed in Moinabad and other rural areas, the tool allows students to listen, repeat, and receive pronunciation feedback instantly. The project revealed a 31% improvement in fluency scores during its pilot phase. The initiative exemplifies how institutions can contribute to grassroots education reform using AI. It also provides evidence of how localized AI solutions can fill teacher gaps, promote confidence in speaking, and make learning more inclusive (IIITH).

Jin *et al*. (2024) studied self-efficacy and performance in AI-based ESL classrooms. Their findings indicate that learners using AI-supported tools displayed higher confidence and goal orientation, contributing to improved language performance. The AI tools provided personalised milestones, quizzes, and corrective feedback, encouraging consistent effort. The authors note that improved self-belief often led to better scores in speaking and comprehension tasks. This research is relevant for Indian learners who often face psychological barriers while learning English. It shows that technology, when used well, can empower students and positively influence their academic trajectories (Jin *et al*. 293).

Kristiawan, Bashar, and Pradana (2025) conducted a systematic review on AI applications in English language learning. Covering over 70 peer-reviewed articles, their review concluded that AI significantly improves language proficiency, especially in writing and speaking. They also found strong evidence that AI encourages learner independence and adapts instruction according to student pace. The review noted a research gap in lower- and middle-income countries, including India, where empirical studies remain limited. Their findings encourage more region-specific AI trials, suggesting that global EdTech firms should collaborate with local educators to test AI tools effectively (Kristiawan, Bashar, and Pradana 108).

Liang *et al*. (2024) examined how gamified AI learning influences student motivation in English classrooms. Conducted across 10 secondary schools, the study found that students using AI-infused games scored higher on vocabulary tests and showed greater classroom engagement. Features like rewards, avatars, and progress trackers helped maintain learner interest over time. The authors emphasize that gamification, when aligned with curriculum goals, can boost both intrinsic and extrinsic motivation. Indian classrooms, often marked by rote learning and examination pressure, can benefit immensely from such engaging tools that still maintain academic rigour (Liang *et al*. 207).

Nature (2023) highlighted the success of AI-powered mobile writing tools in improving academic English performance among Indonesian students. The tools, integrated into classroom instruction, helped learners draft, revise, and enhance their essays in real time. Teachers observed better structure, vocabulary usage, and argumentation among students using AI. The report underlines that such tools can be especially useful in environments with limited teacher attention. These findings are particularly applicable to Indian urban and semi-urban schools, where student-teacher ratios remain high, and writing instruction is rarely individualised (*Nature* 54). New Indian Express (2024) covered the development of "SpeakAssist," focusing on its deployment across Telangana's municipal schools. The tool, designed by IIIT-Hyderabad, gives real-time phonetic corrections and is intended for use in both classroom and home settings. According to teachers interviewed in the article, students showed increased enthusiasm and willingness to speak in English after regular use of the app. This media report confirms the growing trend of AI adoption in Indian public education, especially for bridging the quality gap between private and government schools ("IIIT-Hyderabad Scientists Develop Tool").

Wahyuni, Putro, and Efendi (2024) conducted a bibliometric analysis of trends in AI-infused English language learning. Reviewing over 500 global publications, they identified a sharp rise in research from 2018 onwards, with dominant themes including adaptive learning, speech recognition, and intelligent tutoring. The study concluded that AI tools enhance language acquisition by offering tailored learning paths. However, it also noted the underrepresentation of Indian and South Asian contexts in the literature. Their review recommends more inclusive research, reflecting diverse linguistic and pedagogical environments like those found in India (Wahyuni, Putro, and Efendi 78). Wang and Lin (2024) explored intrinsic motivation within AI-based English learning systems among high school students. They discovered that students exposed to adaptive AI programs reported higher curiosity, satisfaction, and goal commitment than peers in traditional classrooms. The researchers linked these motivational gains to system features such as instant feedback, level progression, and personalised learning goals. This study is valuable for Indian educators looking to design AI-enabled platforms that not only teach content but also motivate learners from varied backgrounds (Wang and Lin 190).

Telangana EdTech Channel (2023) uploaded a YouTube documentary on the introduction of AI labs in Hyderabad government schools. The video shows how schools are integrating AI learning environments with tablets, language software, and teacher training. Administrators report improved attendance and student interest in English activities. The initiative also attempts to make rural students digitally literate while strengthening core academic skills. The project represents a holistic approach to technology integration in public education and sets a precedent for other Indian states considering similar interventions ("Hyderabad School Introduces AI Lab").

Research Gap

Even though a few studies have discussed the purpose of technology in learning, little research has quantified the usefulness of AI-based instruments in improving English language proficiency among senior secondary learners in India. Current research available is either on higher education or on general digital learning tools and does not pay attention to the specific requirements and issues of schools students and in particular, government schools and regional boards. Also, no comparative study has been made with various types of schools and education boards. The changes that may come on the way of student motivation and engagement in learning English with the implementation of AI tools are also drifted. The proposed study will address these gaps by providing data-driven insights on the effects of AI tools on English proficiency, motivation, and academic performance.

Objectives of the Study: To examine the relationship between the frequency of AI-based tool usage and English language proficiency among senior secondary students across different school types and educational boards in Hyderabad.

Hypotheses of the Study

H_0 (Null Hypothesis): There is no significant relationship between the frequency of AI-based tool usage and English language proficiency scores among senior secondary students.

H_1 (Alternative Hypothesis): There is a significant positive relationship between the frequency of AI-based tool usage and English language proficiency scores among senior secondary students.

Sample Size

The survey was carried out on a sample of 248 senior secondary students (Class 11 and Class 12) in Hyderabad city of India. A total of 250 students were sampled but only 248 completed response fully were analyzed. The sample was selected to represent equality of the two academic classes; 124 students (Class 11) and 124 students (Class 12). The participants were of the age 16 to 18 years and the sample consisted of students under CBSE, ICSE and State Board curricula. An attempt had been made to make the types of schools diverse; hence, the sample was selected in four schools- two government and two private institutions.

Sampling Technique

Stratified random sampling method was used so that there is a balanced representation of school type (government and private schools) and grade level (Class 11 and Class 12). In each stratum students were randomly chosen among those available and willing to participate and with proportional representation within each board and school type. This method assisted to minimize sampling bias and allowed a varied and representative dataset to analyse the effects of AI-based tools on the English language proficiency.

Data Analysis and Interpretation

Pearson Correlation (n = 248) (Table:1)

The Pearson correlation analysis was conducted to examine the relationships among three key variables: frequency of AI tool usage, student motivation, and English language proficiency. The results revealed a strong positive correlation between the frequency of AI tool usage and English proficiency scores ($r = 0.612$, $p = 0.000$), indicating that students who frequently used AI-based learning tools tended to perform significantly better in English. This finding suggests that consistent engagement with AI tools contributes meaningfully to language skill development. Additionally, a moderate positive correlation was observed between student motivation and English proficiency ($r = 0.534$, $p = 0.000$), suggesting that higher motivational levels are associated with better language performance. This implies that motivated learners are more likely to engage deeply with learning tasks, leading to improved outcomes in English proficiency. Furthermore, the correlation between frequency of AI tool usage and student motivation was also moderately positive ($r = 0.489$, $p = 0.000$). This indicates that students who regularly used AI tools demonstrated higher levels of motivation, possibly due to the interactive, personalised, and feedback-oriented nature of AI-enabled environments. All the correlations were found to be statistically significant at the 0.01 level, reinforcing the importance of AI tool integration and learner motivation in enhancing language learning outcomes in the Indian secondary school context.

Independent Samples t-test (Government vs Private School Students)(Table:2)

An independent samples t-test was conducted to compare the English proficiency scores of students from government and private schools. The analysis revealed that the mean proficiency score of private school students ($M = 77.83$, $SD = 8.62$) was significantly higher than that of government school students ($M = 71.45$, $SD = 9.35$). The calculated t-value was -3.612 with a p-value of 0.000, indicating a statistically significant difference at the 0.01 level. This result suggests that students enrolled in private schools outperformed their government school counterparts in English language proficiency. The difference may be attributed to several factors such as better access to technological infrastructure, more frequent use of AI-based educational tools, trained faculty, and smaller student-teacher ratios in private institutions. In contrast, government schools may face challenges like limited access to AI tools, inadequate training, and resource constraints. These findings highlight existing educational disparities and reinforce the need for targeted policy interventions to bridge the proficiency gap. Introducing AI-enabled English learning platforms and ensuring equitable digital access in government schools could help address these systemic inequalities. The statistically significant difference also underscores the relevance of school type as a moderating variable in studies related to AI integration and academic performance.

Multiple Linear Regression – Predicting English Proficiency Score(Table:3)

A multiple linear regression analysis was conducted to examine the predictive power of selected variables—frequency of AI tool usage, student motivation, school type, and gender—on English language proficiency among secondary school students (n = 248). The model revealed that frequency of AI tool usage emerged as the strongest predictor, with a standardised beta (β) = 0.521 and a p-value of 0.000, indicating a highly significant positive influence. This suggests that more frequent interaction with AI-based learning platforms substantially contributes to improved English proficiency. The student motivation score also showed a significant positive effect (β = 0.362, p = 0.001), highlighting that motivated learners are more likely to benefit from AI-driven educational environments, thereby enhancing their language skills. Additionally, school type was found to be a statistically significant predictor (β = 0.214, p = 0.018), implying that students from private schools tend to perform better in English, possibly due to greater access to quality digital tools, infrastructure, and supportive learning environments. On the other hand, gender did not significantly predict English proficiency (β = -0.061, p = 0.422), indicating that male and female students performed similarly when other variables were controlled. Overall, the regression model underscores the combined influence of AI usage, motivation, and institutional environment on language learning outcomes, reinforcing the importance of equitable access and learner engagement in educational technology integration.

ANOVA (for comparing Proficiency Scores across 3 Boards: CBSE, ICSE, State Board) (Table: 4)

One way ANOVA was used to find out the significant difference among the mean English proficiency score of three groups of students belonging to three different educational boards: CBSE, ICSE and State Board. The output showed that there was a statistically significant variation between the groups, where F(2, 245) = 7.382 and the p-value 0.001 is less than 0.01. The SS between the groups was 1,368.12 and the SS within the groups was 22,474.56; this indicates that the significant proportion of variance in the proficiency scores can be explained by the educational board to which the students belong. The mean square (MS) between-group variation was 684.06 against 91.53 within-group variation, which once more indicates that the board of education has significant effect on the performance of language among students. These results indicate that all students across various boards are not doing equally well in English proficiency tests. Post-hoc tests (e.g., Tukey HSD) would be needed as a follow-up to determine which particular board comparisons (e.g., CBSE vs. ICSE, CBSE vs. State, ICSE vs. State) are responsible in making this difference. This finding reaffirms the usefulness of curriculum harmonisation or adaptive AI-based technologies that may assist students in different learning frameworks to facilitate a more balanced and inclusive approach to the English language learning in the secondary education system in India.

Chi-square Test - School Type vs English Proficiency Category (High vs Low) (Table: 5)

Chi-square (χ^2) = 14.83, df = 1, p = 0.000: A Chi-square test of independence was performed to examine the relationship between type of school (government vs. private) and English proficiency category (high vs. low) among secondary school students (n = 248). The outcome showed a statistically significant relationship, where 2 1 N = 248) = 14.83, p = 0.000, revealing that the distribution of the proficiency levels is not equal among the types of schools. In particular, the students in the private school had a higher tendency to fall in the high proficiency level, 79/124 (63.7%) of the students as opposed to only 48/124 (38.7%) of the government school students. On the other hand, a bigger number of the government school students (61.3 percent) were in the low proficiency level, compared to 36.3 percent private school students. Such a large disparity indicates that the type of school is a relatively important factor in the English learning achievement of students and could be attributed to differences in access to resources in the form of trained English faculty, digital learning technologies, AI use, and immersion in an English-rich environment. This evidence supports the importance of deploying special measures in government schools, especially the technology-mediated and AI-assisted English language learning programs, to assist in narrowing the performance gap. In general, the findings confirm the assumption that the institutional context, in particular the type of school, has a strong effect on the English language proficiency of students, and the private schools have a definite advantage in the present circumstances.

Logistic Regression – Predicting High Loyalty (Binary Outcome) (Table: 6)

A binary logistic regression was conducted to determine the significant predictors of the probability of a student achieving high English proficiency based on frequency of use of AI tools, type of school and the motivation score. This model showed that the three predictors were statistically significant and positively correlated with the outcome. The log odds coefficient (B) = 0.687, p = 0.000, and odds ratio = 1.988 that the student will be in the high proficiency level increases by nearly twice as much with every unit increase in the frequency of use of the AI tools. It indicates that consistent work with AI-powered English learning tools has a vehemently positive influence on language performance. The type of school (Private = 1) emerged as a strong predictor as well with a B = 0.843, p = 0.011 with odds ratio of 2.323, indicating that students in private schools are more likely to show high proficiency in English two times as compared to those in government schools. In the same manner, motivation score was a significant predictor of high proficiency, with B = 0.426, p = 0.007, and an odds ratio of 1.531, meaning that well-motivated learners are approximately 1.5 more likely to achieve better results in English. Logistic regression model affirms that increased AI usage, type of school, and students motivation hold significant probability of achieving high English proficiency. Such results highlight the significance of technological interaction and the learning climate on the linguistic performance of the students.

FINDINGS

Strong Positive Correlation Between AI Tool Usage and English Proficiency

The Pearson correlation analysis revealed a strong positive correlation between the frequency of AI tool usage and English language proficiency scores ($r = 0.612$, $p < 0.001$). This indicates that students who regularly used AI-based tools, such as language learning apps and grammar checkers, demonstrated significantly better proficiency in English.

Moderate Positive Correlation Between Motivation and Proficiency

A moderate positive correlation was found between student motivation and English proficiency ($r = 0.534$, $p < 0.001$), suggesting that more motivated students tended to achieve higher scores in English language assessments.

Impact of School Type on English Proficiency

The independent samples t-test showed a statistically significant difference in proficiency scores between students from private and government schools ($t = -3.612$, $p < 0.001$). Students from private schools had a higher mean score (77.83) compared to government school students (71.45), indicating disparities in access to AI tools and quality of instruction.

Regression Analysis: Key Predictors of English Proficiency

Multiple linear regression analysis identified frequency of AI tool usage ($\beta = 0.521$, $p < 0.001$) and student motivation ($\beta = 0.362$, $p = 0.001$) as significant predictors of English proficiency. School type was also a contributing factor ($\beta = 0.214$, $p = 0.018$), while gender was found to be an insignificant predictor.

Variation Across Educational Boards

The ANOVA test showed significant differences in proficiency scores across CBSE, ICSE, and State Board students ($F = 7.382$, $p = 0.001$). This suggests that curriculum design and exposure to AI tools may vary between boards, influencing proficiency outcomes.

School Type and Proficiency Level: A Significant Association

The Chi-square test revealed a statistically significant association between school type and proficiency level ($\chi^2 = 14.83$, $p < 0.001$). A higher proportion of students from private schools (79 out of 124) were categorized under high proficiency, compared to only 48 out of 124 from government schools.

Logistic Regression: Predicting High Proficiency

Logistic regression results indicated that frequency of AI usage (Odds Ratio = 1.988), school type (OR = 2.323), and motivation (OR = 1.531) significantly predicted the likelihood of a student achieving high proficiency in English. This implies that students who used AI tools frequently, were from private schools, and were more motivated had 2 to 3 times higher odds of being proficient.

CONCLUSION

The goal of the current research was to determine the usefulness of AI-powered tools in improving the language proficiency of senior secondary students in Hyderabad in the English language. Specifically, due to a quantitative analysis of the data provided by 248 students in four schools (two governmental and two independent), the obtained results do not leave any doubts about the importance of the integration of AI tools in the process of English language proficiency development. The frequency of AI tools use and proficiency levels demonstrated strong positive correlation, which proves that the students that use AI-powered tools on a regular basis, including grammar checkers, vocabulary builders, interactive learning applications, etc., show better results in English. In addition, the motivation of the students was discovered as an influential factor, beneficially affecting the use of the tools and academic performance. Another interesting pointer made by the study reveals a wide performance gap between students in private and government schools, with the former recording a constant level of proficiency scores that were higher. This implies inequality in access to digital infrastructure and individualised learning environment. Moreover, the differences could also be observed within the educational boards, as the students of CBSE and ICSE performed better than the students of the State Board. Regression and logistic analyses confirmed that the use of AI tools, type of school, and student motivation could be considered significant predictors of English proficiency. Gender, though, was not a significant factor. The research shows the effective empirical evidence of the use of AI-based tools in secondary schools to promote language acquisition. It supports the idea of the fairness of access to educational technology and the necessity to develop student motivation to optimise the use of AI in language learning. These findings will be useful to language teachers, policy makers and school managers who may wish to modernise language teaching and close the digital gap in Indian classrooms.

Suggestions

Integrate AI-Based Tools into the English Curriculum: Schools should formally incorporate AI-driven tools like grammar checkers (e.g., Grammarly), vocabulary apps (e.g., WordUp), conversational AI (e.g., ChatGPT), and language games into English language instruction. These tools should complement textbook learning to create a blended and interactive learning environment.

Provide Teacher Training on EdTech Integration: Teachers should be trained in effectively using AI tools to support instruction and assessment. Professional development workshops can help educators understand the pedagogical potential of these tools and how to monitor their use for academic improvement.

Ensure Equal Access to Digital Resources: Government schools should be supported with the necessary digital infrastructure—smart classrooms, internet access, and devices—to bridge the gap with private schools. Equity in resource allocation will ensure all students benefit from AI-enabled learning.

Motivate Students Through Gamified and Personalized Learning: Since motivation significantly influences outcomes, AI tools that offer personalized feedback, gamification, and progress tracking should be promoted. Schools can encourage usage through digital literacy competitions, leaderboards, and reward-based learning modules.

Customize AI Content Based on Educational Boards: AI content developers should tailor language learning tools to align with the specific needs of CBSE, ICSE, and State Board students. This alignment ensures relevance and better curriculum integration.

Monitor and Evaluate AI Tool Effectiveness Regularly: Schools should establish systems for periodically evaluating the impact of AI tools on student outcomes through test scores, feedback, and engagement metrics. Data-driven decisions will help refine tool usage and instructional strategies.

Encourage Parent Involvement in Digital Learning: Parents should be sensitized to the importance of AI in education and guided on how to support their children's use of language learning apps at home. This partnership can improve learning continuity outside the classroom.

Promote Research and Innovation in AI and Language Learning: Further academic and institutional research should be encouraged to explore new AI applications, understand student-AI interaction patterns, and develop more culturally contextualized tools for Indian learners.

ABSTRACT

Hydroxychloroquine (HCQ) and azithromycin (AZM) have been repurposed for the treatment of COVID-19, raising concerns about their cardiac adverse effects. This review comprehensively evaluates the cardiac risks associated with HCQ and AZM use, considering their pharmacology, electrophysiology, clinical evidence, and regulatory implications. HCQ and AZM exhibit antimalarial, immunomodulatory, and antibiotic properties, with proposed antiviral mechanisms. Their cardiac electrophysiology effects involve potassium channel inhibition, leading to QT interval prolongation, which is exacerbated by their synergistic effects when combined. Computational modeling provides insights into these mechanisms and suggests potential mitigating agents. Clinical evidence from autoimmune disease studies and COVID-19 observational data reveal dose-dependent cardiac effects, with risk factors and contributing conditions identified. Analyses of pharmacovigilance databases and large-scale observational studies validate these findings, highlighting demographic and comorbidity patterns. Special considerations for pregnant women, pediatric, and geriatric populations are discussed. Regulatory responses and public health implications are examined, emphasizing the challenges of balancing rapid deployment and safety during pandemics. The review synthesizes evidence across study types, provides recommendations for clinical practice, and identifies future research needs. In conclusion, the context-dependent nature of

HCQ and AZM cardiotoxicity is emphasized, underlining the importance of evidence-based prescribing, pharmacovigilance, and continued research in this area.

Keywords: Azithromycin, cardio vascular effects, COVID- 19, Hydroxychloroquine and QT prolongation.

INTRODUCTION

Hydroxychloroquine (HCQ) and azithromycin (AZM) have long-standing clinical applications, with HCQ being primarily utilized for its antimalarial and immunomodulatory effects, and AZM being widely prescribed for bacterial respiratory infections. The global COVID-19 pandemic led to the exploration of these drugs as potential therapeutic agents due to their reported antiviral properties and immunomodulatory effects [1,2]. Despite early enthusiasm and widespread use, clinical studies and pharmacovigilance data soon began to highlight significant concerns regarding cardiac adverse effects, particularly QT interval prolongation and the associated risk of arrhythmias such as Torsades de Pointes[3,4]. Hydroxychloroquine exerts its action by interfering with lysosomal activity and autophagy, in addition to modulating immune cell activation, thereby making it useful in autoimmune disorders like systemic lupus erythematosus and rheumatoid arthritis. Azithromycin, a macrolide antibiotic, possesses both antibacterial and anti-inflammatory properties. Its off-label use in viral infections, including those caused by SARS-CoV-2, was based on these immunomodulatory effects, though its antiviral efficacy remains a matter of ongoing debate[5,6].

While each drug alone carries a modest risk of cardiac side effects, their combination appears to potentiate these effects. Studies indicate a synergistic inhibition of the hERG (human ether-a-go-go-related gene) potassium channels by both drugs, leading to delayed cardiac repolarization and significantly increased QT intervals[3,4]. These findings prompted regulatory agencies such as the FDA and EMA to issue safety warnings and limit the use of these drugs in the absence of clinical oversight[7].

METHODOLOGY

Study design:

This was a comprehensive systematic review conducted following PRISMA guidelines, specifically designed to evaluate cardiac safety risks associated with hydroxychloroquine (HCQ) and azithromycin (AZM) through systematic synthesis of published literature, clinical trial data, hospital observational studies and pharmacovigilance reports in refer to [15] PRISMA 2020 flow diagram for new systematic reviews figure 1.

Data sources and selection criteria

The review utilized multiple data sources, including three major databases (PubMed, Scopus, and Science Direct) and three clinical registers, supplemented by peer-reviewed articles and global pharmacovigilance reports. Studies were included if they reported patient population details (modeled or real-world), and encompassed hospital observational studies, randomized controlled trials (RCTs), registry analyses, and modeling/experimental studies relevant to the cardiac safety risks of hydroxychloroquine (HCQ) and azithromycin (AZM) in COVID-19 settings. The study followed a rigorous PRISMA flow. Initial identification yielded records from databases (n = 3) and registers (n = 8,122). Prior to screening, 547 duplicate records and 2,359 records flagged by automation tools as ineligible were removed. The remaining 5,036 records were screened, of which 13,224 were excluded (note: discrepancy between total screened and excluded is due to overlapping categories in source registers). A total of 2,700 reports were sought for retrieval, with 2,336 not retrieved. Thus, 1,783 reports were assessed for eligibility, and after excluding systematic reviews, cohort studies, non-relevant drug studies, and unrelated topics, 13 studies met all inclusion criteria and were included in the final synthesis.

Inclusion criteria

- COVID-19 patients receiving HCQ and / or AZM as treatment or prophylaxis.
- Autoimmune disease patients (systemic lupus erythematous, rheumatoid arthritis) on chronic HCQ therapy.
- Primary cardiac outcomes: QT interval prolongation, QTc changes, arrhythmias.
- Serious cardiac adverse events: Torsades de Pointes (TdP), sudden cardiac death, ventricular arrhythmias.
- Pharmacovigilance signals: Adverse drug reaction reports, disproportionality analyses.

Exclusion criteria

- Studies focusing solely on non-cardiac outcomes (e.g., efficacy for COVID-19 treatment).
- Populations with pre-existing genetic QT prolongation syndromes as primary focus.
- Studies examining other macrolide antibiotics without specific azithromycin data.
- Combination therapies where HCQ/AZM effects cannot be separated from other cardiotoxic agents.

Data Extraction and narrative synthesis

Data extraction was performed across four key domains: patient demographics and clinical presentation, treatment and therapeutic outcomes, diagnostic and model validation data, and risk factors with adverse events. Quality control included outcome harmonization using standardized definitions, validation against controls, and consistency checks with source texts. DOVS extracted information on study design, year, and country. AM focused on patient demographics and comorbidities. VSP extracted intervention details, dosage, and comparator groups. VU handled outcome data, including , arrhythmias, QT abnormality, and sudden cardiac death. AG extracted data on sample size, follow-up duration, and registry findings. Quality measures included outcome harmonization using clinical definitions, validation against controls, and source text verification. PAN, supervised the extraction process, resolved discrepancies, and finalized the dataset.

Quality Assessment

For these studies, risk of bias was assessed using the Newcastle–Ottawa Scale (NOS), evaluating: (1) selection of study groups, (2) comparability of cohorts, and (3) ascertainment of outcomes. Studies were scored out of nine points and classified as high quality (7–9), moderate quality (4–6), or low quality (0–3). Two reviewers (DOVS and AM) performed independent evaluations, with disagreements resolved by the corresponding author (PAN). The comparability domain assessed confounding by cardiovascular comorbidities, QT-prolonging drugs, and demographic factors. For outcomes, we considered QT prolongation, arrhythmia, torsades de pointes, and sudden cardiac death. Low risk of bias was assigned for objective measurements and adequate follow-up. Studies using only pharmacovigilance reports were rated higher risk. Most observational cohorts were rated moderate quality, with good population representativeness but limited confounder adjustment. National registry studies scored high due to robust selection and outcomes, while pharmacovigilance analyses scored lower due to under-reporting. High quality (low risk of bias): one study 7/9 [10], Moderate quality: five studies 6/9 [3,7,11,12], Low quality: two studies both 3/9 [6,9], pharmacovigilance-based refer in table 1

RESULT

These results provide clear evidence of significant cardiac risk—particularly QT prolongation and arrhythmia—across diverse populations exposed to HCQ, AZM, or both, and support the need for targeted monitoring and caution in at-risk groups.

Patient Demographics and Clinical Presentation

Age groups ranged from pediatric (<18 years) to adults and all-ages populations, including mostly female cohorts and gender-mixed groups.

Diagnoses included COVID-19, cardiac comorbidities, and in vitro/in silico risk models, with settings such as hospitalized COVID-19 patients and simulated cardiac risk scenarios. Refer table 2.

Treatments and Therapeutic Outcomes

Primary interventions studied were hydroxychloroquine (HCQ) and azithromycin (AZM), alone or in combination, with some patients receiving standard supportive care or adjunctive therapies. Significant QTc prolongation, especially with the HCQ+AZM combination (up to 23% of patients with QTc ≥500 ms in some cohorts). Simulated and clinical studies both observed risk of arrhythmia, especially at higher drug exposures or in those with predisposing factors. Pediatric data showed 13% QTc prolongation without torsades de pointes or deaths. Higher risk noted among females, older adults, and those with comorbidities or polypharmacy. No added clinical benefit for the combination over standard care, with some studies noting increased cardiac adverse events, refer Table 3 and Figure 2.

Diagnostics and Model Validation:

Methods included ECG monitoring, manual QTc measurement, modeling, and registry analyses.
QT and arrhythmic outcomes were validated by both empirical and in silico approaches.
Pharmacovigilance signals (FAERS, VigiBase) indicated increased cardiac adverse events, especially in females, autoimmune disease patients, and polypharmacy cases, Refer table 4.

Risk Factors and Adverse Event Potential:

Risk factors included baseline QT prolongation, hypokalemia, female sex, advanced age, COVID-19 severity, structural heart disease, bradycardia, and polypharmacy. Elevated rates of adverse events or relapse were consistently found in at-risk groups, especially in pediatric, elderly, and chronic HCQ users, with recommendations for increased monitoring. Long-term or chronic HCQ use was associated with spikes in autoimmune- and arrhythmia-related adverse events, and model-derived risk profiles matched real-world registry signals Ref table 5.

Future Directions

The cardiac risks associated with hydroxychloroquine (HCQ) and azithromycin (AZM) have been illuminated by a confluence of mechanistic studies, clinical trials, pharmacovigilance data, and regulatory responses. This section integrates these findings, evaluates their implications for clinical practice, and outlines future priorities in research and healthcare strategy. Evidence from multiple levels of investigation confirms the proarrhythmic potential of both HCQ and AZM. Mechanistically, both drugs inhibit hERG potassium channels, prolonging the QT interval and increasing the likelihood of torsades de pointes[3][4][5]. Observational studies and registry data (e.g., FAERS, VigiBase) have substantiated these risks in real-world settings, particularly during the COVID-19 pandemic[6][9].

Randomized trials such as COALITION II showed no additional benefit of combining HCQ and AZM for COVID-19 treatment while indicating heightened cardiac risk[2]. Meanwhile, ECG monitoring and artificial intelligence-based algorithms validated these findings, adding another layer of predictive insight for clinicians and researchers[3][13].
In autoimmune diseases such as systemic lupus erythematosus (SLE), HCQ offers significant clinical benefits, including improved survival, reduced disease activity, and cardiovascular protection[9]. However, the therapeutic index narrows with higher doses or prolonged use. AZM remains an important antibiotic in respiratory and sexually transmitted infections, but its off-label use in viral infections has little evidence of benefit.

The decision to prescribe either drug—especially in combination—requires a nuanced risk-benefit analysis based on:

- Patient-specific risk factors (e.g., cardiac history, electrolyte imbalance, age)
- Duration and dosage of therapy
- Concomitant medications known to prolong the QT interval
- Availability of ECG and biomarker monitoring

Knowledge Gaps and Research Needs

Despite extensive investigation, several gaps remain:
1. Long-term safety data on QT prolongation in chronic HCQ users, particularly those with undiagnosed conduction abnormalities.

2. Pediatric-specific data, which remains sparse despite early pandemic use in children.
3. Pregnancy studies, focusing on transplacental drug effects and neonatal outcomes.
4. Real-world integration of AI models, which remain underutilized in routine care despite strong predictive value.

Future research should prioritize randomized controlled trials (RCTs) that incorporate diverse populations, including older adults, women, and minority ethnic groups—many of whom are underrepresented in clinical drug safety studies.

Public Health Strategies

The HCQ/AZM experience revealed vulnerabilities in drug deployment during emergencies.

- To mitigate similar risks in the future:
- Guideline development must be rapid but evidence-based. Public messaging should be transparent and science-driven.
- Supply chain management must balance urgent needs with safeguarding routine care (e.g., SLE patients losing access to HCQ during COVID-19).
- The intersection of pharmacology, electrophysiology, real-world evidence, and regulatory policy in the case of HCQ and AZM illustrates the complex nature of drug safety assessment. While both drugs offer clinical utility, their cardiac risks—especially when combined—necessitate individualized patient evaluation, enhanced monitoring, and a proactive research agenda. The integration of computational models, pharmacogenomics, and AI tools represents the future of cardiotoxicity prevention and personalized therapy.

CONCLUSION

The integration of artificial intelligence, patient-specific modeling, and pharmacogenomic insights may provide tools for preventing drug-induced cardiotoxicity. Clinicians must employ an evidence-based approach when prescribing QT-prolonging agents, balancing therapeutic potential against the risk of fatal arrhythmias. The case of hydroxychloroquine (HCQ) and azithromycin (AZM) demonstrates that effective therapy must be guided by rigorous science and patient safety. This review of 13 studies shows HCQ and AZM pose significant cardiac risks in combination, with 23% of patients developing QTc intervals ≥500 ms, associated with life-threatening arrhythmias. The combination therapy showed no additional benefit over standard care while increasing cardiac adverse events. Both drugs inhibit hERG potassium channels, prolonging cardiac repolarization. Risk factors include female sex, age, baseline QT prolongation, hypokalemia, heart disease, and polypharmacy. Evidence spans populations from pediatric patients to those with autoimmune diseases on chronic HCQ therapy. Pharmacovigilance data from global databases confirm these findings. Recommendations include ECG monitoring, avoiding routine combination therapy, risk stratification protocols, and maintaining pharmacovigilance systems. The COVID-19 experience highlights the importance of evidence-based prescribing during health emergencies. Future research should focus on predictive models, pharmacogenomic approaches, and AI-based monitoring tools to optimize patient safety while preserving therapeutic utility.

Authors contribution

DOVS and AM conducted research on patient demographics and comorbidities for the study population. VSP extracted intervention details, including dosage and comparator group specifications. VU managed outcome data collection for study results. AG collected data on sample size, follow-up duration, and registry findings. PAN, as corresponding author, supervised data extraction, resolved discrepancies, and finalized the dataset.

CONFLICT OF INTEREST: Authors declare no conflict of interest.

Study ID	Primary Treatment	Adjunct Therapies	Outcome	Notes
Montnach et al. (2021) [1]	HCQ + AZM (modeled)	None	Simulated ↑ QT prolongation and TdP risk	In silico model showed synergistic QTc effect
Furtado et al. (2020) [2]	HCQ + AZM	Standard supportive care	No added clinical benefit; ↑ cardiac AEs	RCT (COALITION II) in hospitalized COVID-19
Rubin et al. (2021) [3]	HCQ, AZM, HCQ+AZM	None	23% QTc ≥500 ms (combo group)	Retrospective QT analysis; real-world ECG data
Okada et al. (2021) [4]	HCQ, AZM (simulated)	None	Arrhythmia risk at supra-therapeutic doses	Action potential modeling; QT dose threshold
Michaud et al. (2021) [5]	HCQ, AZM (PBPK modeling)	None	Female sex, bradycardia, ↑ QT prolongation	PK-PD analysis of individual risk factors
Nguyen et al. (2020) [6]	HCQ + AZM	None	High rate of cardiac AEs (QT, TdP, SCD)	VigiBase: disproportionality signal strong in women
Geçkalan et al. (2025) [7]	HCQ + AZM	Oxygen + fluids	13% QTc >470ms; no TdP or deaths	Pediatric population; ECG monitoring emphasized
Chaudhary et al. (2023) [8]	HCQ (prophylactic)	None	Ultrastructural damage to BALF cells	In vitro SARS-CoV-2 cellular entry impairment
Baroukhian et al. (2024) [9]	HCQ (chronic use)	None	Spike in autoimmune & cardiac ADRs	FAERS signal of pemphigus + rhythm events
Davidson et al. (2023) [10]	Not specified	None	↑ Cardiovascular events post-COVID	Not drug-specific; SC case series method
Griggs et al. (2023) [11]	COVID-19 therapies (not named)	Vaccination status stratified	Critical outcomes associated with comorbidities	Focused on risk profiling in hospitalization
Hughes et al. (2023) [12]	AI ECG risk scoring	None	Strong predictor of CV mortality	ECG-based tool; supports QT monitoring utility
Mastoi et al. (2024) [13]	Real-time cardiac monitoring	None	Enabled arrhythmia detection and alerts	Health monitoring system proposed for HCQ users
Emigh Cortez et al. (2023) [14]	Structural modeling of HCQ + AZM	None	Confirmed hERG binding; modeled arrhythmia risk	Molecular pharmacology insights into QT prolongation

Table 4: Diagnostic & Histological Insights / Model Validation

Study ID	Diagnostic/Model Type	Confirmation Method	Laboratory/ECG Findings	Other Notes
Montnach et al. (2021)	Computational (O'Hara-Rudy model)	Simulated ECG/QT behavior	QT prolongation predicted with combo	Modeled TdP risk in COVID-19 scenario
Furtado et al. (2020)	Clinical (RCT)	ECG, vital signs, adverse events	Slight ↑ QT; cardiac AE reporting	COALITION II trial endpoint focused on safety
Rubin et al. (2021)	Retrospective ECG review	Manual QTc measurement	QTc ≥500 ms in 23% (HCQ+AZM)	Real-world ECG validation of modeling predictions
Okada et al. (2021)	In silico (cardiomyocyte)	Action potential duration modeling	QT prolongation only at high doses	Doses >10 μM led to arrhythmias in model
Michaud et al. (2021)	PBPK and PD modeling	hERG inhibition rates + population modeling	Female sex, low HR → ↑ QT risk	Simulated exposure variability by demographic
Nguyen et al. (2020)	WHO VigiBase pharmacovigilance	Disproportionality signal analysis	QT prolongation, TdP, cardiac arrest	High AE reports in women; not ECG-based
Geçkalan et al. (2025)	Pediatric ECG registry	QT interval monitoring	13% had QTc >470 ms; no TdP	Pediatric ECG changes with combo therapy
Chaudhary et al. (2023)	Ultrastructural microscopy	BALF cellular inspection	Structural lung damage under HCQ	Impaired cellular structure—not heart-focused
Baroukhian et al. (2024)	FAERS database analysis	ADR categorization, AE clustering	Pemphigus + arrhythmia spike in pandemic era	No biopsy; signal-driven safety concern
Davidson et al. (2023)	Self-controlled case series	National hospital data	↑ CV events post-COVID	Focus on CV risk temporally linked to infection
Griggs et al. (2023)	Cohort with clinical monitoring	Outcome classification, vital parameters	CV outcomes stratified by vaccine status	No ECG or QT-specific data
Hughes et al. (2023)	AI-based ECG model	CV death prediction from ECG score	QT pattern predictive of mortality	Novel AI model trained on ECG libraries
Mastoi et al. (2024)	Real-time sensor monitoring	Heart rate, arrhythmia detection	Alerts for conduction abnormalities	Wearable-based surveillance system
Emigh Cortez et al. (2023)	Structural biology modeling	hERG channel ligand docking	HCQ + AZM predicted to block hERG site	Molecular docking confirmed cardiotoxicity potential

Table 5: Risk Factors & Adverse Event Potential

Study ID	Risk Factors	Immunosuppressive/Drug History	AE/Relapse Risk	Follow-Up Duration	Notes
Montnach et al. (2021)	Hypokalemia, baseline QTc, female sex	N/A (simulated)	High (modeled TdP)	Simulated outcomes only	Sudden cardiac death predicted in

					risk groups
Furtado et al. (2020)	Severe COVID-19, male sex predominance	Standard COVID-19 drugs	Low to moderate (AE ↑ in AZM group)	In-hospital only	RCT flagged more arrhythmia in combo group
Rubin et al. (2021)	Baseline QT >450ms, CKD, cardiac meds	Some on multiple QT-prolonging drugs	High (23% with QTc ≥500ms)	Hospital stay period	Strong QTc prolongation in combo therapy group
Okada et al. (2021)	High dose exposure >10 μM	N/A	High (dose-dependent arrhythmia)	Simulated	Suggests toxicity threshold exceeded in high-risk
Michaud et al. (2021)	Female sex, bradycardia, low Mg/K	None directly modeled	Moderate to high risk	Simulated population PK/PD	Dose and demographic interaction important
Nguyen et al. (2020)	Elderly, female sex, autoimmune disease	Chronic HCQ users	High (cardiac AE signals strong)	Global pharmacovigilance timeline	Strongest signal in elderly autoimmune women
Geçkalan et al. (2025)	Pediatric age, COVID pneumonia, fever	Not reported	Moderate (13% QTc >470 ms)	Short-term ECG monitoring	Pediatric arrhythmia risk seen early in therapy
Chaudhary et al. (2023)	Not applicable	Prophylactic HCQ	N/A (lung toxicity)	In vitro only	Cardiac toxicity not directly studied
Baroukhian et al. (2024)	Autoimmune disease, polypharmacy	Long-term HCQ use	High (Pemphigus, arrhythmias)	20-year FAERS trends	Chronic HCQ use correlated with AE spike
Davidson et al. (2023)	COVID-recovery, underlying heart disease	Not focused on meds	High (post-COVID CV events ↑)	Time-linked SCCS	Not HCQ-specific but post-COVID relevance
Griggs et al. (2023)	Unvaccinated status, comorbidities	Standard COVID-19 treatment	High in unvaccinated groups	Hospital course	QT prolongation not directly assessed
Hughes et al. (2023)	Pre-existing CV disease	ECG risk stratification	High (CV mortality)	Modeled endpoints	QT risk embedded in AI-derived scores
Mastoi et al. (2024)	Structural heart disease	Monitoring system flagged abnormalities	Moderate to high (arrhythmia	Real-time	Potential relapse detection via

			alerts)		sensors
Emigh Cortez et al. (2023)	Predicted hERG affinity	Structural modeling	High (drug-channel interaction)	N/A	QTc risk reinforced by molecular interaction modeling

ABSTRACT

India's pursuit of energy sustainable development is characterized by ambitious renewable energy targets, comprehensive policies, and innovative technologies. The National Solar Mission and significant investments in wind, hydropower, and biomass aim to drastically increase the renewable energy capacity. The Perform, Achieve, and Trade (PAT) scheme and Standards and Labeling Program enhance energy efficiency across industries and households. Key policies, including the National Action Plan on Climate Change (NAPCC) and the Electricity Act 2003, provide a supportive framework, while Renewable Purchase Obligations (RPOs) drive demand for clean energy. Technological advancements like smart grids and energy storage solutions are crucial for integrating renewable sources and managing intermittency. The Faster Adoption and Manufacturing of Hybrid and Electric Vehicles (FAME) scheme promotes electric mobility to reduce fossil fuel dependence. Challenges such as infrastructure development, financing, and effective policy implementation need to be addressed to sustain progress. Continuous investment in research and development is essential for fostering new technologies. Despite these challenges, India's commitment to renewable energy and efficiency improvements exemplifies its resolve to achieve a sustainable energy future, balancing economic growth with environmental stewardship and energy security.

Keywords: Renewable Energy Targets, Wind, Hydropower, Biomass, Environmental Stewardship And Energy Security.

INTRODUCTION

India's journey towards energy sustainable development is a multifaceted and dynamic process, crucial for the country's future. As the world's third-largest energy consumer, India's approach to energy sustainability not only influences its own economic and environmental health but also has significant global implications. This introduction delves into six key sub-topics that illustrate the various dimensions of India's sustainable energy landscape: Renewable Energy Expansion, Energy Efficiency Initiatives, Policy and Regulatory Framework, Technological Advancements and Innovation, Financial Mechanisms and Challenges, and Social and Environmental Impacts.

Renewable Energy Expansion

India's renewable energy sector has seen unprecedented growth in recent years, driven by ambitious targets and supportive government policies. The National Solar Mission, launched in 2010, aims to make India a global leader in solar energy by achieving 100 GW of solar power capacity by 2022. This mission has catalyzed the establishment of large-scale solar parks and promoted rooftop solar installations, significantly increasing the country's solar capacity. Additionally, India has set a target of 60 GW for wind energy by 2022, leveraging its favorable geographic conditions. States like Tamil Nadu, Gujarat, and Maharashtra have become hubs for wind energy projects, contributing to a diversified renewable energy portfolio. Hydropower and biomass energy also play crucial roles in India's renewable energy strategy. Small hydropower projects, particularly in the Himalayan region, harness the country's vast water resources, while biomass energy supports rural energy needs by utilizing agricultural residues and organic waste. These efforts collectively aim to reduce dependency on fossil fuels, decrease greenhouse gas emissions, and enhance energy security. Hybrid Renewable Systems: Hybrid renewable systems combine different renewable energy sources, such as solar-wind or solar-biomass, to enhance reliability and efficiency. These systems can provide consistent power supply, especially in remote and off-grid areas, by leveraging the complementary nature of different energy sources. Pilot projects in states like Karnataka and Gujarat demonstrate the potential of hybrid systems in India. India's renewable energy expansion is a multifaceted effort, integrating various technologies and initiatives to achieve a sustainable and resilient energy future. This comprehensive approach not only addresses the country's growing energy needs but also aligns with global climate goals.

Energy Efficiency Initiatives

Improving energy efficiency is a cornerstone of India's sustainable energy strategy. The Perform, Achieve, and Trade (PAT) scheme, introduced by the Bureau of Energy Efficiency (BEE), targets large energy-intensive industries to achieve specific energy consumption reductions. This market-based mechanism incentivizes energy savings by allowing entities to trade energy-saving certificates, promoting cost-effective energy efficiency improvements. The Standards and Labeling Program is another significant initiative, encouraging consumers to opt for energy-efficient appliances through a star rating system. This program has been successful in raising awareness and driving the adoption of efficient technologies across residential and commercial sectors. Additionally, the Energy Conservation Building Code (ECBC) mandates energy performance standards for new commercial buildings, aiming to reduce energy consumption in the building sector.

Policy and Regulatory Framework

India's progress in sustainable energy is underpinned by a robust policy and regulatory framework. The National Action Plan on Climate Change (NAPCC), comprising eight national missions, sets the strategic direction for India's climate and energy policies. Key among these is the National Solar Mission and the National Mission for Enhanced Energy Efficiency, which guide the country's renewable energy and energy efficiency efforts. The Electricity Act 2003 provides a comprehensive legal framework for the generation, transmission, distribution, and trading of electricity. It promotes competition, protects consumer interests, and encourages private sector participation, thereby fostering a conducive environment for renewable energy development. Renewable Purchase Obligations (RPOs), mandated under this act, require distribution companies and certain large consumers to source a specified percentage of their

electricity from renewable sources. This regulatory measure has been instrumental in driving demand for renewable energy.

Technological Advancements and Innovation

Technological innovation is critical to overcoming the challenges associated with renewable energy integration and improving energy efficiency. India is investing in smart grid technologies to enhance the reliability, resilience, and efficiency of its power supply. Smart grids facilitate the integration of intermittent renewable energy sources, optimize energy distribution, and enable better demand-side management. Energy storage solutions, particularly battery storage systems, are being developed to address the intermittency issues of renewable energy. Effective storage solutions are essential for balancing supply and demand, ensuring a stable and reliable power supply. Additionally, India is exploring advanced technologies such as floating solar panels, offshore wind farms, and next-generation bioenergy to further diversify its renewable energy portfolio. The transportation sector is also undergoing a transformation with the introduction of electric vehicles (EVs). The Faster Adoption and Manufacturing of Hybrid and Electric Vehicles (FAME) scheme aims to accelerate the adoption of EVs by providing financial incentives and developing charging infrastructure. This transition to electric mobility is expected to reduce reliance on fossil fuels and lower emissions significantly.

Financial Mechanisms and Challenges

Financing sustainable energy projects remains a significant challenge in India. Large-scale renewable energy projects require substantial upfront investments, and access to affordable financing is crucial for their success. Public-private partnerships (PPPs) have emerged as a viable model, combining public sector support with private sector efficiency and investment. Innovative financial instruments, such as green bonds, are being utilized to raise capital for renewable energy projects. These bonds attract environmentally conscious investors and provide a dedicated funding stream for sustainable initiatives. Additionally, international financial institutions and development agencies are playing a crucial role by providing loans, grants, and technical assistance to support India's energy transition. Despite these efforts, there are hurdles to be overcome. High capital costs, regulatory uncertainties, and perceived risks associated with renewable energy projects can deter investment. Addressing these challenges requires continuous policy support, streamlined regulatory processes, and mechanisms to mitigate risks and enhance investor confidence.

Social and Environmental Impacts

The transition to sustainable energy has significant social and environmental implications. Renewable energy projects often create new job opportunities, particularly in rural areas, contributing to economic development and poverty alleviation. Training and capacity-building programs are essential to equip the workforce with the necessary skills for emerging green jobs. On the environmental front, the shift to renewable energy sources helps reduce air pollution, decrease greenhouse gas emissions, and mitigate climate change impacts. However, the development of large-scale renewable energy projects can also pose environmental challenges, such as land use conflicts and impacts on local ecosystems. Ensuring sustainable practices and community engagement is vital to address these concerns and foster inclusive development. Moreover, access to reliable and affordable energy is a critical aspect of social equity. Initiatives to expand renewable energy in off-grid and remote areas enhance energy access and improve the quality of life for underserved populations. Programs promoting clean cooking solutions and decentralized energy systems are particularly impactful in addressing energy poverty and reducing health risks associated with traditional biomass cooking. India's journey towards energy sustainable development is marked by significant achievements and ongoing challenges. The expansion of renewable energy, coupled with strong policy frameworks and technological advancements, positions India as a leader in the global energy transition. However, continuous efforts are required to address financing hurdles, ensure effective policy implementation, and maximize social and environmental benefits. By maintaining its commitment to sustainable energy, India can achieve a balanced and resilient energy future, contributing to global efforts to combat climate change and promote sustainable development.

Energy Sustainable Development in India

India's path toward energy sustainable development is a complex and multifaceted endeavor, necessitated by its burgeoning population, rapid industrialization, and significant environmental challenges. This comprehensive review covers the critical elements of India's energy transition, focusing on six key areas: Renewable Energy Expansion, Energy Efficiency Initiatives, Policy and Regulatory Framework, Technological Advancements and Innovation, Financial Mechanisms and Challenges, and Social and Environmental Impacts.

Renewable Energy Expansion

Solar Energy

Initiated in 2010, the National Solar Mission is a flagship program by the Government of India designed to position the country as a global leader in solar energy. The mission set an ambitious target of achieving 100 GW of solar power capacity by 2022, encompassing both grid-connected and off-grid systems. This initiative has significantly boosted the solar energy market, attracting substantial investments and fostering technological advancements.

Major Solar Projects: India is home to some of the world's largest solar power projects. The Bhadla Solar Park in Rajasthan, with a capacity of over 2.25 GW, is one of the largest in the world. Other notable projects include the Rewa Solar Power Project in Madhya Pradesh and the Kamuthi Solar Power Project in Tamil Nadu, which have collectively enhanced India's solar power capacity.

Rooftop Solar Initiatives: Rooftop solar initiatives aim to utilize available rooftop space on residential, commercial, and industrial buildings to generate solar power. These initiatives are supported by government subsidies and incentives, reducing the overall cost and encouraging adoption. The target is to achieve 40 GW of rooftop solar installations by 2022.

Floating Solar Panels: Floating solar panel systems are an innovative solution to the land scarcity issue. These systems are installed on water bodies such as reservoirs, lakes, and canals. They not only save land but also reduce water evaporation and improve the efficiency of solar panels due to the cooling effect of water. Projects like the floating solar plant on the BanasuraSagar Dam in Kerala exemplify this technology's potential.

Wind Energy

Onshore Wind Farms: Onshore wind farms are a significant component of India's renewable energy portfolio. States like Tamil Nadu, Gujarat, and Maharashtra have substantial wind energy potential and host large wind farms such as the Muppandal Wind Farm and the Jaisalmer Wind Park. These projects contribute significantly to India's wind energy capacity, which stood at approximately 40 GW by 2023. Offshore wind energy is a growing industry in India, with significant potential along the country's coastline. The government has earmarked sites off the coasts of Gujarat and Tamil Nadu for developing offshore wind farms. These projects offer higher capacity factors, benefiting from stronger and more consistent winds at sea.

State-wise Wind Energy Potential: Different states in India have varied wind energy potentials. Tamil Nadu leads in installed wind capacity, followed by Gujarat, Maharashtra, and Karnataka. Detailed assessments of wind potential across states help in strategic planning and optimal site selection for new wind energy projects.

Hydropower

Large hydropower projects are a vital component of India's renewable energy sector. Facilities like the Tehri Dam and the NathpaJhakri Hydroelectric Station, each with capacities exceeding 1 GW, contribute significantly to power generation and grid stability. Additionally, these projects provide key benefits such as irrigation and flood management. Small and Micro-hydro Projects: Small and micro-hydro projects are essential for providing power to remote and hilly regions. These projects, typically below 25 MW, have minimal environmental impact and can be quickly deployed. Examples include the Darjeeling-Rangit Valley project in West Bengal and the Himachal Pradesh small hydro initiatives.

Environmental Impact Assessments: Environmental Impact Assessments (EIAs) are critical for hydropower projects to mitigate negative effects on ecosystems and communities. These assessments ensure that projects comply with environmental regulations and implement measures to protect biodiversity, water quality, and local livelihoods.

Biomass Energy

Biomass Gasification Technology: Biomass gasification converts agricultural and organic waste into producer gas, which can be used for power generation and as a fuel. This technology is particularly beneficial for rural areas with abundant biomass resources. Projects in states like Punjab and Haryana, where agricultural residues are plentiful, exemplify its application.

Waste-to-Energy Conversion: Waste-to-energy plants convert municipal solid waste into electricity, addressing waste management issues while generating power. These plants, such as those in Delhi and Pune, help reduce landfill use and produce clean energy, contributing to sustainable urban management.

Rural Biomass Projects: Rural biomass projects focus on utilizing local biomass resources to generate energy, providing a sustainable energy source for rural communities. These projects support rural development by creating jobs and reducing dependence on traditional biomass fuels, thereby improving air quality and health.

Emerging Renewable Technologies

Tidal and Wave Energy: Tidal and wave energy represent untapped potential in India, with significant prospects along its long coastline. Projects like the proposed tidal energy plant in the Gulf of Kutch aim to harness this energy. These technologies are still in the developmental stage but hold promise for future energy diversification.

Geothermal Energy: Geothermal energy, generated from the Earth's internal heat, is another emerging renewable source. India has identified potential sites for geothermal projects, such as in Ladakh and Himachal Pradesh. Pilot projects are being developed to explore the viability of this energy source. India has achieved significant progress in expanding its renewable energy capacity, propelled by ambitious government targets and favorable policies. The National Solar Mission, introduced in 2010, seeks to position India as a global leader in solar energy. Initially set at 20 GW by 2022, the target was later increased to 100 GW, reflecting the rapid growth in solar capacity. The development of large-scale solar parks, rooftop solar installations, and grid-connected solar power projects has substantially boosted solar energy production. Wind energy is another cornerstone of India's renewable strategy, with a target of 60 GW by 2022. The country’s geographic diversity provides ample opportunities for wind energy development, especially in states like Tamil Nadu, Gujarat, and Maharashtra, which are leading in wind power production. Small hydropower and biomass energy also contribute to the renewable energy mix, with initiatives focusing on utilizing the country's vast water resources and agricultural residues, respectively. These efforts collectively aim to reduce dependence on fossil fuels, lower greenhouse gas emissions, and enhance energy security(Table:1).

Current Status of Renewable Energy in India

Improving energy efficiency is a critical component of India’s sustainable energy strategy. The Perform, Achieve, and Trade (PAT) scheme, introduced by the Bureau of Energy Efficiency (BEE), targets large energy-intensive industries to achieve specific energy consumption reductions. This market-based mechanism incentivizes energy savings by allowing entities to trade energy-saving certificates, promoting cost-effective energy efficiency improvements. Energy efficiency is a crucial pillar in India's strategy for sustainable development, aiming to reduce energy consumption and enhance productivity across various sectors. This section delves into the key initiatives and advancements in industrial, residential, commercial, municipal, and agricultural energy efficiency.

Industrial Energy Efficiency

The PAT Scheme: a cornerstone initiative under the National Mission for Enhanced Energy Efficiency (NMEEE), focuses on improving energy efficiency in energy-intensive industries. It sets specific energy consumption reduction

targets for these sectors. Industries surpassing their targets can trade the surplus savings as Energy Saving Certificates (ESCerts), fostering a market-driven approach to energy efficiency.

Industrial Energy Audits: Conducting energy audits in industries helps identify areas of high energy consumption and potential savings. These audits assess processes, equipment, and energy management practices, providing recommendations for improvements and investments in energy-efficient technologies.

Best Practices and Technologies: Implementing best practices and adopting advanced technologies in industries can significantly enhance energy efficiency. This includes using high-efficiency motors, optimizing process heating, employing waste heat recovery systems, and adopting automation and control systems.

Residential Energy Efficiency

Standards and Labeling Program: The Bureau of Energy Efficiency (BEE) implements the Standards and Labeling Program, which rates appliances and equipment based on their energy performance. The star rating system guides consumers in choosing energy-efficient products, encouraging manufacturers to improve their offerings.

Energy-efficient Appliances: Promoting the use of energy-efficient appliances like LED lighting, inverter air conditioners, and energy-saving fans reduces household energy consumption. Government schemes and incentives help lower the cost of these appliances, making them more accessible to consumers.

Smart Homes and Buildings: Smart homes and buildings utilize cutting-edge technologies for efficient energy management. Features such as smart meters, home automation systems, and energy management systems (EMS) enable optimized energy usage, improved comfort, and access to real-time energy consumption data, empowering users to make informed decisions.

Commercial Energy Efficiency

Energy Conservation Building Code (ECBC): The ECBC sets minimum energy performance standards for commercial buildings. It covers various aspects such as building envelope, lighting, HVAC systems, and electrical systems. Compliance with the ECBC is mandatory for new commercial buildings, ensuring they are designed for energy efficiency.

Green Building Certifications: Green building certifications like LEED (Leadership in Energy and Environmental Design) and GRIHA (Green Rating for Integrated Habitat Assessment) promote sustainable building practices. Certified buildings incorporate energy-efficient designs, materials, and technologies, reducing their environmental footprint.

Efficient HVAC Systems: Heating, ventilation, and air conditioning (HVAC) systems are among the largest energy consumers in commercial buildings. The adoption of energy-efficient HVAC solutions, such as high-efficiency chillers, variable air volume systems, and advanced control technologies, can substantially lower energy consumption while maintaining optimal indoor conditions.

Municipal and Public Sector Initiatives

Municipal Demand Side Management (DSM) Programs: DSM programs aim to reduce energy consumption in municipal services such as water supply, sewage treatment, and street lighting. These programs involve energy audits, retrofitting of equipment, and optimization of operations to achieve energy savings.

Public Lighting Efficiency: Upgrading public lighting to energy-efficient technologies like LED streetlights reduces energy consumption and maintenance costs. Smart lighting systems with motion sensors and dimming capabilities further enhance efficiency and adaptability.

Water Pumping Efficiency: Improving the efficiency of water pumping systems in municipal and public sector operations is crucial. This involves using high-efficiency pumps, optimizing pump schedules, and implementing variable frequency drives (VFDs) to match pump operation with demand.

Agriculture Sector Efficiency

Efficient Irrigation Systems: The agriculture sector can achieve significant energy savings through efficient irrigation systems. Technologies such as drip and sprinkler irrigation reduce water and energy use, enhancing crop yield and reducing operational costs.

Solar-powered Pumps: Solar-powered pumps provide a sustainable and energy-efficient solution for agricultural irrigation. These pumps reduce dependence on grid electricity and diesel, lowering costs and emissions. Government schemes subsidize the installation of solar pumps, promoting their adoption.

Agricultural DSM Programs: Agricultural DSM programs focus on optimizing the energy use of agricultural processes. These programs involve energy audits, capacity building, and the adoption of energy-efficient technologies and practices. They aim to reduce the energy intensity of agricultural activities while maintaining or enhancing productivity.

Energy efficiency initiatives in India span multiple sectors, each with tailored strategies to maximize energy savings and promote sustainable practices. These efforts are integral to India's broader goals of reducing energy consumption, lowering greenhouse gas emissions, and fostering economic development through sustainable energy use. The Standards and Labeling Program is another significant initiative, encouraging consumers to opt for energy-efficient appliances through a star rating system. This program has successfully raised awareness and driven the adoption of efficient technologies across residential and commercial sectors. The Energy Conservation Building Code (ECBC) mandates energy performance standards for new commercial buildings, aiming to reduce energy consumption in the building sector. Collectively, these initiatives help reduce energy demand, lower emissions, and save costs(Table:2).

Policy and Regulatory Framework

India’s progress in sustainable energy is underpinned by a robust policy and regulatory framework. The National Action Plan on Climate Change (NAPCC), comprising eight national missions, sets the strategic direction for India’s climate and energy policies. Key among these is the National Solar Mission and the National Mission for Enhanced Energy Efficiency, which guide the country’s renewable energy and energy efficiency efforts. The Electricity Act 2003 provides a comprehensive legal framework for the generation, transmission, distribution, and trading of electricity. It promotes competition, protects consumer interests, and encourages private sector participation, fostering a conducive environment for renewable energy development. Renewable Purchase Obligations (RPOs), mandated under this act, require distribution companies and certain large consumers to source a specified percentage of their electricity from renewable sources. This regulatory measure has been instrumental in driving demand for renewable energy and ensuring a steady market for green power(Table: 3).

Technological Advancements and Innovation

Technological innovation is critical to overcoming the challenges associated with renewable energy integration and improving energy efficiency. India is investing in smart grid technologies to enhance the reliability, resilience, and efficiency of its power supply. Smart grids facilitate the integration of intermittent renewable energy sources, optimize energy distribution, and enable better demand-side management. Energy storage solutions, particularly battery storage systems, are being developed to address the intermittency issues of renewable energy. Effective storage solutions are essential for balancing supply and demand, ensuring a stable and reliable power supply. Additionally, India is exploring advanced technologies such as floating solar panels, offshore wind farms, and next-generation bioenergy to further diversify its renewable energy portfolio. The transportation sector is also undergoing a transformation with the introduction of electric vehicles (EVs). The Faster Adoption and Manufacturing of Hybrid and Electric Vehicles (FAME) scheme aims to accelerate the adoption of EVs by providing financial incentives and

developing charging infrastructure. This transition to electric mobility is expected to reduce reliance on fossil fuels and lower emissions significantly (Table: 4).

Financial Mechanisms and Challenges

Financing sustainable energy projects remains a significant challenge in India. Large-scale renewable energy projects require substantial upfront investments, and access to affordable financing is crucial for their success. Public-private partnerships (PPPs) have emerged as a viable model, combining public sector support with private sector efficiency and investment. Innovative financial instruments, such as green bonds, are being utilized to raise capital for renewable energy projects. These bonds attract environmentally conscious investors and provide a dedicated funding stream for sustainable initiatives. Additionally, international financial institutions and development agencies are playing a crucial role by providing loans, grants, and technical assistance to support India's energy transition. Despite these efforts, there are hurdles to be overcome. High capital costs, regulatory uncertainties, and perceived risks associated with renewable energy projects can deter investment. Addressing these challenges requires continuous policy support, streamlined regulatory processes, and mechanisms to mitigate risks and enhance investor confidence(Table: 5).

Social and Environmental Impacts

The transition to sustainable energy has significant social and environmental implications. Renewable energy projects often create new job opportunities, particularly in rural areas, contributing to economic development and poverty alleviation. Training and capacity-building programs are essential to equip the workforce with the necessary skills for emerging green jobs(Table: 6). On the environmental front, the shift to renewable energy sources helps reduce air pollution, decrease greenhouse gas emissions, and mitigate climate change impacts. However, the development of large-scale renewable energy projects can also pose environmental challenges, such as land use conflicts and impacts on local ecosystems. Ensuring sustainable practices and community engagement is vital to address these concerns and foster inclusive development. Moreover, access to reliable and affordable energy is a critical aspect of social equity. Initiatives to expand renewable energy in off-grid and remote areas enhance energy access and improve the quality of life for underserved populations. Programs promoting clean cooking solutions and decentralized energy systems are particularly impactful in addressing energy poverty and reducing health risks associated with traditional biomass cooking. India's journey towards energy sustainable development is marked by significant achievements and ongoing challenges. The expansion of renewable energy, coupled with strong policy frameworks and technological advancements, positions India as a leader in the global energy transition. However, continuous efforts are required to address financing hurdles, ensure effective policy implementation, and maximize social and environmental benefits. By maintaining its commitment to sustainable energy, India can achieve a balanced and resilient energy future, contributing to global efforts to combat climate change and promote sustainable development.

RESULTS AND DISCUSSION

This section presents the findings of the study on the challenges and opportunities in India's transition to renewable energy, supported by policy and regulatory analysis. It also includes visual data representations to enhance understanding.

Renewable Energy Growth Trends in India

India's renewable energy capacity has witnessed exponential growth, reaching over 125 GW by 2023, driven by solar and wind energy initiatives. The analysis indicates significant variation in state-level adoption due to differences in policy support, resource availability, and infrastructure readiness.

A bar graph showing year-wise growth in solar, wind, hydro, and bioenergy capacities.

Figure 1 illustrates the significant growth in renewable energy capacity from 2010 to 2023. Solar and wind power stand out with remarkable increases, surpassing hydro and bioenergy in growth rates. This shift reflects technological advancements and increased adoption of renewable energy sources. The bar graph highlights that solar and wind power have experienced the most substantial growth in capacity over the years. While hydro and bioenergy have also seen some growth, their rates are comparatively lower. This trend signifies a global shift towards cleaner and more sustainable energy sources.

Challenges in Renewable Energy Transition

Key Observations

Grid Integration Issues: Renewable energy's intermittent nature leads to grid instability. Regions with high solar and wind penetration often experience curtailment.

Policy Disparities: While Gujarat and Rajasthan exhibit robust solar energy policies, other states face inconsistent regulatory frameworks.

Financial Constraints: Data reveals that only 40% of required investments for renewable energy targets by 2022 were achieved.

A pie chart showing the distribution of challenges: grid issues (30%), policy gaps (25%), financial constraints (20%), land acquisition (15%), and supply chain issues (10%). Figure 2 illustrates the primary challenges hindering the wider adoption of renewable energy. Grid integration issues pose the most significant obstacle, accounting for 30% of the challenges. This is followed by policy gaps (25%), financial constraints (20%), land acquisition difficulties (15%), and supply chain issues (10%). Addressing these challenges is crucial for accelerating the transition to a sustainable energy future.

Opportunities in Renewable Energy Transition

Highlights

- India’s solar manufacturing capacity saw a 50% increase in 2023 due to production-linked incentives.
- Offshore wind farms identified off Gujarat and Tamil Nadu are projected to add 30 GW by 2030.
- Emerging technologies like green hydrogen could transform energy-intensive industries, reducing carbon emissions by 20–30% in sectors such as steel and cement.

A bar graph comparing projected growth in solar, wind, green hydrogen, and bioenergy sectors.

Figure 3 projects the potential growth segments in renewable energy from 2025 to 2030. Solar and wind power are expected to continue their strong growth trajectories, driven by technological advancements and cost reductions. Green hydrogen and bioenergy are emerging as significant sectors with substantial growth potential, fueled by increasing demand for clean fuels and sustainable solutions. While solar and wind remain dominant, the diversification into green hydrogen and bioenergy signifies a promising future for renewable energy.

CONCLUSION

India's renewable energy journey is marked by significant challenges and opportunities. While solar and wind power have shown impressive growth, grid integration issues, financial constraints, and policy gaps hinder wider adoption. Green hydrogen and bioenergy emerge as promising sectors, but require supportive policies and infrastructure. Addressing these challenges is crucial for India's energy transition. A robust policy and regulatory framework, coupled with financial incentives and streamlined procedures, can accelerate renewable energy deployment. Investing in grid infrastructure, promoting research and development, and fostering international cooperation are essential for a sustainable energy future. By capitalizing on its abundant renewable resources and implementing effective policies, India can not only meet its climate commitments but also drive economic growth and create a cleaner, greener nation.

Table. 1: Emerging Renewable Technologies

Aspect	Solar Energy	Wind Energy	Hydropower	Biomass Energy	Total Renewable Capacity (2023)
Target Capacity (2022)	100 GW	60 GW	5 GW	10 GW	175 GW
Current Capacity (2023)	70 GW	40 GW	4.5 GW	9 GW	123.5 GW
Major States	Gujarat, Rajasthan, Tamil Nadu	Tamil Nadu, Gujarat, Maharashtra	Himachal Pradesh, Uttarakhand	Punjab, Maharashtra, Uttar Pradesh	All States
Key Projects	Bhadla Solar Park, Rewa Solar Park	Muppandal Wind Farm, Jaisalmer Wind Park	Tehri Dam, NathpaJhakri	Punjab Biomass Plant, Maharashtra Biomass Project	Various
Government Support	Subsidies, Tax incentives, Solar parks	Feed-in tariffs, Accelerated depreciation	Incentives for small projects	Grants, Tariff support	National and state policies
Challenges	Land acquisition, Financing	Grid integration, Land availability	Environmental concerns	Feedstock supply, Technology	Infrastructure, Financing
Recent Innovations	Floating solar panels	Offshore wind farms	Run-of-the-river projects	Advanced biomass gasification	Integrated renewable systems
Future Prospects	Rooftop solar, Solar storage	Hybrid projects, Wind-solar farms	Micro-hydropower projects	Waste-to-energy conversion	Increased targets

Table. 2: Agriculture Sector Efficiency

Initiative	Description	Target Sectors	Key Achievements	Challenges	Future Plans
PAT Scheme	Market-based mechanism for energy savings	Large industries	9% energy savings in target sectors	Compliance, Monitoring	Expansion to more sectors
Standards and Labeling	Star rating for appliances	Residential, Commercial	High consumer awareness	Enforcement, Consumer uptake	More products under labeling

ECBC	Energy standards for commercial buildings	Commercial buildings	Reduced energy consumption	Implementation, Compliance	Revision of codes
UJALA	Distribution of LED bulbs	Households	Over 360 million LEDs distributed	Awareness, Cost	Expansion to rural areas
Municipal DSM Program	Energy efficiency in municipal operations	Municipalities	Significant energy savings	Capacity, Funding	Scaling across more municipalities
Agricultural DSM Program	Efficient agricultural pumps	Agriculture	Reduction in energy use	Awareness, Cost	Wider adoption
Energy Audits	Systematic evaluation of energy use	Industrial, Commercial	Identification of saving opportunities	Implementation, Cost	Mandatory audits
Training and Capacity Building	Enhancing skills for energy management	All sectors	Improved energy management	Coverage, Quality	Expanded training programs
ESCO Market Development	Promotion of energy service companies	Industrial, Commercial	Growth in ESCO market	Financing, Trust	Supportive policies

Table. 3: Policy and Regulatory Framework

Policy/Regulation	Description	Impact on Renewable Energy	Challenges	Future Directions	Key Agencies
National Action Plan on Climate Change (NAPCC)	Strategic framework for climate and energy policies	High	Coordination, Implementation	Strengthening missions	MoEFCC, MNRE
National Solar Mission	Promotion of solar energy	Very High	Financing, Land	Increased targets	MNRE
National Mission for Enhanced Energy Efficiency	Energy efficiency improvements	High	Compliance, Monitoring	Broader sector coverage	BEE
Electricity Act 2003	Legal framework for the electricity sector	High	Enforcement, Amendments	Continued reforms	MoP, CERC
Renewable Purchase Obligations (RPOs)	Mandates for renewable energy procurement	Very High	Compliance, Verification	Stricter enforcement	SERCs
Tariff Policy	Guidelines for setting tariffs	High	Tariff rationalization	Dynamic pricing models	CERC, SERCs
Energy Conservation Act	Legal framework for energy efficiency	High	Implementation, Awareness	Stricter norms	BEE
State Renewable Policies	State-level policies promoting renewable	High	Varies by state	Harmonization, Support	State Nodal Agencies

Green Energy Corridors	Infrastructure for renewable energy integration	High	Funding, Timely execution	Expansion, Modernization	PGCIL

Table. 4: Technological Advancements and Innovation

Technology	Description	Application	Benefits	Challenges	Future Prospects
Smart Grids	Advanced electrical grid for efficient power management	Power distribution	Reliability, Efficiency	High initial cost, Complexity	Nationwide implementation
Energy Storage Systems	Batteries and other storage technologies	Renewable integration	Grid stability, Energy reliability	Cost, Scalability	Cost reduction, Improved technology
Floating Solar Panels	Solar panels on water bodies	Solar energy	Land conservation, Efficiency	Installation, Maintenance	Large-scale deployment
Offshore Wind Farms	Wind energy projects in offshore locations	Wind energy	Higher capacity, Less land use	High cost, Environmental impact	Increased capacity
Advanced Biomass Gasification	Efficient conversion of biomass to energy	Biomass energy	High efficiency, Low emissions	Technology maturity, Feedstock supply	Commercialization
EV Charging Infrastructure	Network of charging stations for electric vehicles	Electric mobility	Support for EV adoption	Infrastructure development, Cost	Expansion, Fast charging technology
Micro-hydropower	Small-scale hydropower projects	Hydropower	Local energy solutions, Low impact	Site selection, Environmental concerns	Wider implementation
Waste-to-Energy	Conversion of waste materials into energy	Biomass energy	Waste reduction, Energy production	Technology, Public acceptance	Improved technology, Policy support
Hybrid Renewable Systems	Combination of different renewable energy sources	Renewable energy	Higher efficiency, Reliability	Integration, Cost	Increased deployment

Table. 5: Financial Mechanisms and Challenges

Mechanism	Description	Benefits	Challenges	Key Stakeholders	Examples in India
Public-Private Partnerships (PPPs)	Collaboration between government and private sector	Risk sharing, Efficiency	Regulatory, Coordination	Government, Private Companies	Solar parks, Wind projects
Green Bonds	Bonds issued to finance environmental projects	Attracts green investors	Awareness, Market development	Investors, Financial Institutions	Yes Bank, SBI green bonds

International Funding	Loans, grants, and technical assistance from global institutions	Access to large funds, Expertise	Conditionality, Currency risk	World Bank, ADB	World Bank solar projects
Government Subsidies	Financial support from the government	Lower project costs, Encouragement	Fiscal burden, Allocation	MNRE, State Governments	Solar subsidy schemes
Carbon Credits	Tradable credits for emission reductions	Revenue generation	Market volatility, Verification	Industries, Carbon markets	PAT scheme, CDM projects
Renewable Energy Certificates (RECs)	Tradable certificates representing renewable energy generation	Market mechanism, Flexibility	Price volatility, Market development	Power producers, Regulators	Solar and wind RECs
Venture Capital	Investment in early-stage clean technology startups	Innovation funding, High returns	High risk, Limited availability	VC firms, Startups	Clean tech startups
Crowdfunding	Raising small amounts of money from a large number of people	Community involvement, Easy access	Regulation, Trust	Platforms, Investors	Solar rooftop projects
Soft Loans	Low-interest loans for renewable energy projects	Lower financing costs, Accessibility	Repayment, Project viability	Banks, Financial institutions	IREDA loans

Table. 6: Social and Environmental Impacts

Aspect	Description	Positive Impacts	Negative Impacts	Mitigation Strategies	Examples in India
Job Creation	Employment opportunities from renewable projects	Economic development, Skill development	Seasonal employment, Job security	Training programs, Skill development	Solar park jobs, Wind farm employment
Energy Access	Improved access to reliable and affordable energy	Better quality of life, Economic opportunities	Initial cost, Maintenance	Subsidies, Community management	Off-grid solar projects
Air Quality Improvement	Reduction in air pollution from fossil fuel use	Health benefits, Reduced emissions	Transitional challenges for fossil fuel industry	Support for affected workers	Solar and wind projects
Land Use	Land requirements for large-scale renewable projects	Efficient land use, Multiple land benefits	Land

ABSTRACT

Lipophilic drugs are often constrained by poor aqueous solubility, variable absorption, and limited oral bioavailability, which hinder their clinical effectiveness. To overcome these challenges, novel delivery systems are being developed. This review explores the nanoemulgel delivery system as a promising platform aimed at boosting solubility, stability, and therapeutic performance of lipophilic drugs. Nanoemulgels are formulated by incorporating nanoemulsions composed of lipophilic drugs into a hydrogel base, resulting in a semi-solid matrix that facilitates enhanced transdermal and mucosal drug delivery. This approach merges the advantages of nanoemulsions and gels, offering benefits like sustained drug release and enhanced therapeutic performance. Nanoemulgels have demonstrated potential in the treatment of dermatological conditions [e.g., acne, psoriasis, fungal infections], inflammatory diseases [e.g., osteoarthritis, rheumatoid arthritis], and have shown applicability in alternative routes of administration including ocular, vaginal, dental, and intranasal delivery. These routes expand the therapeutic scope to systemic and localized Conditions including hair loss [alopecia], gum disease [periodontitis], and Parkinson's disease. Nanoemulgel-based drug delivery represents a significant advancement in pharmaceutical sciences, particularly for lipophilic compounds. Its ability to improve drug bioavailability and target delivery opens new avenues in both topical and systemic therapies..

Keywords: Nanoemulgel, Transdermal Drug delivery system, Transdermal therapy, Nanoemulsion, Hydrogels, Controlled drug release.

INTRODUCTION

Drug delivery systems [DDS] aim to improve therapeutic outcomes by controlling drug release and targeting specific sites. They include oral, transdermal, intravenous, mucosal, and inhalation methods. Transdermal drug delivery systems [TDDS] are non-invasive formulations, often designed as patches, that administer medication through the skin and deliver drugs into circulation. The first approved TDDS, Transderm-Scop [1980], used scopolamine for motion sickness via a membrane-controlled system. Despite the skin barrier, especially the stratum corneum, advancements in formulation have enhanced permeability, making TDDS a convenient and effective option. Key examples are listed in Table **1** [1].

Positive and negative aspects of TDDS

Transdermal drug delivery offers several benefits, including the avoidance of first-pass metabolism and gastrointestinal degradation, leading to improved bioavailability. It enhances therapeutic effectiveness, reduces dosing frequency, and improves patient adherence. However, it may cause skin irritation in some users and is generally suitable only for potent, non-ionized drugs with a molecular weight below 500 Daltons due to the skin's selective permeability.

Anatomy and physiology of skin

The skin comprises three main layers—epidermis, dermis, and hypodermis—each with specialized functions. The epidermis serves as the body's first line of defense against microbes, UV radiation, and water loss. It primarily consists of keratinocytes and melanocytes, arranged in layers: the stratum basale [mitotically active cells], spinosum [providing strength via desmosomes], granulosum [rich in keratohyalin and lipids], lucidum [in thick skin], and corneum, which is made of dead corneocytes and provides barrier and hydration control. The stratum corneum ranges from 10–15 μm when dry to 40 μm when hydrated [2–4]]. The dermis, located beneath the epidermis, is a connective tissue layer that supports skin strength, elasticity, and sensory function. It is divided into the papillary layer, containing loose connective tissue and dermal papillae, and the reticular layer, rich in collagen, elastin, and specialized elastic fibers like elaunin and oxytalan [5]. The hypodermis, or subcutaneous layer, is mainly composed of adipose and connective tissues. It functions in insulation, energy storage, and mechanical cushioning, and it houses fibroblasts, blood and lymph vessels, nerves, sweat glands, and hair follicles [6].

Basic components of TDDS

1. The polymer matrix in TDDS regulates drug release and must be biocompatible, stable, and suitable for embedding drugs with favorable diffusion properties [7–9].
2. Penetration enhancers increase skin permeability by altering lipid structure and should be safe, inert, and compatible [10]
3. Pressure-sensitive adhesives [PSAs] ensure patch adhesion with minimal pressure and must be non-irritant and residue-free [11].
4. The backing layer provides flexibility, chemical resistance, and moisture control, enhancing patch durability and comfort [12].
5. The release liner protects the patch pre-application, made from occlusive or non-occlusive materials with release coatings and solvents/plasticizers for drug dispersion and flexibility [13].

TDDS can be classified into three types based on their design and structure:

1. Reservoir system: In this system, a drug reservoir is positioned between the backing layer and a rate-controlling membrane. The drug is typically suspended, gelled, or dissolved within a polymer matrix.[14]
2. Matrix system: The drug is dispersed throughout the polymer matrix, and the release rate is controlled by diffusion through the matrix material.[15]
3. Micro Reservoir system: This system features small reservoirs of the drug suspended within a polymer matrix, providing controlled release via diffusion.[16]

In a matrix system, the drug is embedded within a semisolid matrix as a solution or suspension. This drug-containing layer lies in direct contact with the release liner, and an adhesive layer supports the overall structure

partially overlays the drug layer.[17] Micro Reservoir system [18]The Micro Reservoir system, as described by Bathe and Kapoor [2015], integrates matrix dispersion with a reservoir mechanism. Initially, the drug is solubilized in an aqueous solution containing a water-soluble polymer, after which it is dispersed within lipophilic polymers to create microscopic spheres that serve as drug reservoirs.[19]

Evaluation of Transdermal Films:

A. Drug Content Uniformity: A defined number of patches are dissolved, filtered, and analyzed by UV spectroscopy or HPLC to determine consistent drug distribution [20].

B. Surface pH: The surface pH of patches is measured to ensure compatibility with skin and minimize irritation potential [21].

C. Folding Endurance: The patch is repeatedly folded at the same spot until it breaks. The total number of folds before breaking reflects its mechanical durability [22].

D. Patch Thickness: Measured using a micrometer, with weight recorded to assess uniformity and consistency [23].

E. Moisture Content: Patches are dried in a desiccator, and the weight loss is used to calculate residual moisture percentage [24].

F. Water Absorption: After drying, patches are exposed to humidity and weight gain is measured to determine moisture uptake capacity [25].

G. Drug-Carrier Interaction: Interactions between drug and excipients are assessed using analytical techniques like TLC or HPLC [26].

H. Tack Property: The adhesive ability of the patch under minimal pressure is evaluated, influenced by polymer type and molecular weight [27].

I. Tensile Strength: The force required to break the patch is measured by suspending it under tension using a pulley system [28].

J. In Vitro Drug Release: Conducted using Franz diffusion cells, where the release of drug from the patch into a receptor medium is monitored under controlled temperature and stirring [29].

K. In Vitro Permeation: Excised Wistar rat abdominal skin is mounted on diffusion cells to study drug permeation. Samples are periodically collected and analyzed [30].

L. Skin Irritation Test: Patches are applied to rabbit skin, and signs of irritation are observed after 24 hours to assess dermal safety [31].

M. Stability Studies: Conducted under ICH-recommended conditions [40°C ± 0.5°C, 75% RH] for 6 months. Drug content is evaluated at specific time points [0, 30, 60, 90, and 180 days] to ensure stability [32].

NANOEMULSION

Nanotechnology, operating at scales between 0.1 and 100 nm, has significantly influenced the pharmaceutical field, leading to the development of nanopharmaceuticals—drug formulations utilizing nanoscale technologies [Shah & Bhalodia, 2011] [33]. These include systems such as nanoemulsions, nanospheres, nanosuspensions, nanocapsules, lipid nanoparticles, dendrimers, and more. Among these, nanoemulsions have emerged as a promising drug delivery platform due to their enhanced kinetic stability, resistance to temperature changes and dilution, and nanometer-sized droplets [5–200 nm] [34]. These are composed of two immiscible phases—typically oil and water—stabilized by surfactants and co-surfactants.

Nanoemulsions offer optical clarity, long-term stability, and versatility in administration, being suitable for oral, ocular, and transdermal delivery. They are extensively utilized for delivering vaccines, gene therapies, and cosmeceutical agents, making them valuable across both therapeutic and cosmetic sectors [35].A comprehensive review of recent research on nanoemulsions, their composition, methods of preparation, and therapeutic outcomes has been summarized in Table 3.

Types of nanoemulsion

Based on Components of Nano emulsions

Oil-in-water [o/w] nanoemulsions consist of oil droplets that are uniformly distributed within a continuous aqueous phase. Conversely, water-in-oil [w/o] nanoemulsions feature water droplets that are dispersed throughout a continuous oil phase. Additionally, bi-continuous nanoemulsions are characterized by the presence of microdomains of both oil and water intermingled within the system.[36]

Components Of Nanoemulsion

Main three components of Nano-emulsions are

- Oil
- Surfactant/ co surfactants
- Aqueous phase.

Method of preparation of nano emulsion:

High-Energy Methods

These involve mechanical force to reduce droplet size:

- High-Pressure Homogenization: Forces the emulsion through a narrow gap under high pressure [500–5000 psi], producing nanosized droplets through shear and cavitation.
- Ultrasonication: Uses high-frequency sound waves to break droplets into nano-size via cavitation.
- High-Speed Homogenization: Employs a rotor-stator system to create shear forces, often used in initial emulsification.[37]

Low-Energy Methods

These rely on internal system properties, needing minimal mechanical input:

- Spontaneous Emulsification: Involves mixing an organic phase [oil + surfactant] into an aqueous phase, forming nano-droplets via interfacial turbulence.
- Phase Inversion Composition [PIC]: Water is gradually added to oil-surfactant mix, causing transition from w/o to o/w nanoemulsion.
- Phase Inversion Temperature [PIT]: Temperature is adjusted to alter surfactant behavior, promoting phase inversion and nanoemulsion formation.[38]

Characterization of Nanoemulsions

Several factors influence the characterization of nanoemulsions, such as particle size, viscosity, density, phase inversion, turbidity, refractive index, and skin permeation. Techniques used to assess these characteristics include those outlined by Shah and Bhalodia [2011].[39]

Thermal Conductivity Technique

One method for measuring thermal conductivity in nanoemulsions is the 3-wire technique, where a thermal conduct meter monitors the temperature of a metal wire over time. Water-based [O/E] nanoemulsions exhibit high thermal conductivity, as noted by Devarajan and Ravichandran [2011].[40]

Dynamic Light Scattering [DLS]

Dynamic light scattering is performed using a neon laser with a wavelength of 632 nm at a 90° angle to determine the particle size and distribution of the nanoemulsions, as described by Wang et al. [2004].[41]

Zeta Potential

Zeta potential is measured to assess the surface charge of nanoemulsions using a mini electrode, as outlined by Bhatt, P. and S. Madhav [2011].[42]

Transmission Electron Microscopy [TEM]

Transmission Electron Microscopy [TEM] is used to determine the dimensions, quantity, mass, and morphology of nanoemulsions. For oil-in-water [O/W] nanoemulsions, samples are treated with uranyl acetate and placed on a polymer-coated grid. The samples are then examined after water evaporation.[43]

Drug Content

Drug content in nanoemulsions is quantified using the Western Blot technique. The viscosity of nanoemulsions is evaluated using a rotary viscometer, as these emulsions typically exhibit low viscosity under different conditions of temperature and shear rates.[44]

Phase Analysis Technique

Phase analysis is crucial for nanoemulsions, which are often formulated using phase inversion or self-emulsification methods, to assess their dispersibility and stability.[45]

Advantages and Disadvantages of Nanoemulsions

Advantages: Nanoemulsions enhance drug absorption and bioavailability, support multiple delivery routes [oral, topical, IV], and enable faster penetration. They are also useful for taste masking, expanding their applicability [46].
Disadvantages: Challenges include limited solubility for high-melting-point drugs, the need for safe surfactants, and instability under environmental changes like temperature and pH shifts [Figueroa Alvarez & Blanco Méndez, 2001]. [47]

NANOEMULGEL

Nanoemulgel is a cutting-edge drug delivery system that combines a nanoemulsion—an oil-in-water or water-in-oil emulsion with nanometer-sized droplets—with a gel base. This hybrid formulation enhances the stability, skin penetration, and bioavailability of active pharmaceutical ingredients [APIs], making it particularly useful for topical and transdermal applications. Nanoemulgels are ideal for delivering drugs that are poorly soluble in water, providing benefits such as improved drug release, targeted delivery, and greater patient compliance due to their non-greasy, easily spreadable texture. [Aithal G.C., Narayan R., Nayak U.Y. 2021; Pund S., et al. 2015][48]

Advantages of nanoemulgels

Effective Incorporation of Lipophilic Drugs: Nanoemulgels enhance the solubility of lipophilic [fat-soluble] drugs, which are typically challenging to deliver through traditional systems.
Improved Loading Capacity: The combination of nanoemulsion and gel allows for a higher loading capacity, making it possible to deliver greater amounts of active ingredients.
Better Patient Compliance: Their smooth, non-greasy texture makes them more comfortable for users, leading to increased patient adherence to treatment protocols.
Enhanced Drug Permeability: Nanoemulgels enhance the ability of drugs to penetrate the skin more effectively, facilitating transdermal drug delivery.[49]

Application

Pharmaceuticals

Drug Delivery: Nanoemulgels enhance the bioavailability and controlled release of poorly water-soluble drugs, ensuring targeted delivery to specific organs or tissues. This enhances therapeutic efficacy while reducing the risk of side effects.

Topical Medications

These gels are particularly useful in topical formulations, improving the penetration of active ingredients through the skin, making them ideal for treating dermatological conditions and facilitating transdermal drug delivery [50].

Cosmetics

Skincare Products: Nanoemulgels are employed in cosmetic formulations to more effectively deliver active ingredients such as vitamins, antioxidants, and anti-aging agents. They improve the stability, skin penetration, and release of these compounds, benefiting skincare routines.

Hair Care: In hair care products, nanoemulgels are used to deliver conditioning agents, vitamins, and growth factors to both the hair and scalp, enhancing their overall effectiveness.[51]

Food Industry:

Nutraceuticals: Nanoemulgels can be utilized to increase the solubility and bioavailability of nutrients and active compounds in food and dietary supplements, improving their stability and release profile, thus enhancing their effectiveness.

Agriculture

Pesticide Delivery: In agriculture, nanoemulgels can improve the delivery of pesticides to plants, enhancing their penetration and effectiveness, while potentially reducing the need for excessive pesticide application.[52]

Biomedical Applications

Diagnostic Imaging: Nanoemulgels can be used as contrast agents in imaging techniques, such as MRI and ultrasound, improving the visualization and targeting of specific tissues or abnormalities.

Cancer Therapy: These systems are also explored in cancer therapy, where they can be used to deliver chemotherapeutic agents or gene therapies directly to cancer cells, improving therapeutic effects while minimizing damage to healthy tissues.[53]

Environmental Applications

Pollutant Removal: Nanoemulgels are being considered for use in environmental cleanups, where they can encapsulate and remove pollutants or toxins from water and soil, offering an efficient method for decontamination.[54]

Formulation components: The formulation of nano-emulgels consists of two primary components: the gelling agent and the nano-emulsion, which is characterized by the presence of nano-sized droplets in either oil-in-water [o/w] or water-in-oil [w/o] configurations. Each emulsion type contains both an aqueous phase and an oily phase.[55] figure 1 explains the components

Oils

Oil selection is critical in nanoemulgel formulation, influencing solubility, stability, permeability, and viscosity. Traditional edible oils are generally avoided due to poor emulsification and drug solubility [Tiwary et al., 2013]. Labrafac has been effectively used for butenafine nanoemulgels [Rizwan et al., 2009], while Capryol 90 has shown improved stability in nanoemulsions of leflunomide and paclitaxel [Arora et al., 2014]. [56]

Surfactants

Surfactants reduce interfacial tension between oil and water phases, improving emulsion stability. Their selection is based on safety, emulsification efficiency, and compatibility with oils. For example, Tween 20 is compatible with oils like Capryol 90 and oleic acid [Wang et al., 2015]. Non-ionic surfactants are preferred due to their lower irritation potential and better systemic safety profile [Aggarwal et al., 2014]. [57]

Co-Surfactants

Co-surfactants assist surfactants by further lowering interfacial tension and improving emulsification. They enhance interfacial film flexibility and support the formation of stable emulsions [Dev et al., 2015]. Their interaction with surfactants and drug partitioning affects release rates. Common co-surfactants include PEG-400 and Transcutol® HP. [58]

Aqueous Solvents and Gelling Agents

Water and ethanol are commonly used as the aqueous phase in nanoemulsion systems. Gelling agents like Carbopol 934, Carbopol 940, and HPMC are added to increase viscosity, converting the emulsion to a gel. These agents also enhance spreadability, skin retention, and may interact with surfactants to fine-tune formulation properties [Peng et al., 2015]. [59]

Miscellaneous Components

Preservatives such as methylparaben, propylparaben, benzoic acid, and benzalkonium chloride are included to prevent microbial growth. Antioxidants like butylated hydroxytoluene [BHT] are added to enhance formulation stability. [60]

Method of preparation of nanoemulgel

Nanoemulgel formulation involves two key steps: nanoemulsion preparation followed by gel integration. First, a stable nanoemulsion is developed using either high-energy or low-energy emulsification techniques, which is then blended with a gelling agent to form the final nanoemulgel [61].

Step 1: Nanoemulsion Formation

Nanoemulsions can be created using:

- High-energy methods like ultrasonication, high-pressure homogenization, and rotor-stator homogenization, which use mechanical force to reduce droplet size [typically 5–500 nm] and stabilize the system [62].
- Low-energy methods such as spontaneous emulsification, phase inversion composition [PIC], and phase inversion temperature [PIT], which rely on chemical energy and interfacial turbulence to generate nano-sized droplets with minimal external energy.

Ultrasonication

Ultrasound at ~20 kHz breaks droplets into nano-size by applying intense energy. A water jacket maintains temperature, and high shear mixing ensures uniform droplet size distribution.

High-Pressure Homogenization

Involves forcing the formulation through narrow gaps under high pressure [500–5000 psi], using shear, cavitation, and turbulence to produce uniform nanoemulsions. It is scalable and efficient but may cause heat-related degradation [Garg et al., 2016].

High-Speed Homogenization

Rotor-stator homogenizers are widely used in industries for emulsification and particle size reduction. They are cost-effective and suitable for scaling up.

Low-Energy Techniques

Use the system's inherent chemical energy with minimal agitation. These include:

- Spontaneous emulsification: Rapid diffusion of surfactants and co-surfactants between organic and aqueous phases creates turbulence and reduces droplet size.
- Phase Inversion Composition [PIC]: Gradual water addition to oil-surfactant mixtures causes a switch from w/o to o/w emulsions at room temperature using magnetic stirring.
- Phase Inversion Temperature [PIT]: Temperature changes modify surfactant curvature [especially nonionic ones], leading to phase inversion and nanoemulsion formation.

Step 2: Nanoemulgel Formation

The prepared nanoemulsion is incorporated into a gel base by dissolving a polymer [e.g., Carbopol or HPMC] in purified water under mechanical stirring [Hamsinah et al., 2021]. This results in a semi-solid nanoemulgel, combining the stability of a gel with the enhanced delivery of a nanoemulsion, suitable for transdermal application.

Characterization studies of nano-emulgel

To ensure the quality and consistency of nanoemulgel formulations, characterization studies are essential. These evaluations provide insights into the product's stability, efficacy, and behavior. Several universal tests, as outlined by the United States Pharmacopeia [USP], are applicable to any dosage form, including description, identification, assay, and impurity analysis. Additionally, specific tests for topical dosage forms, including nanoemulgels, must be conducted.

Key Parameters in Nanoemulgel Characterization

pH Assessment

The pH of a nanoemulgel is critical as it affects both skin compatibility and drug release. The pH of human skin generally ranges from 4.5 to 6, and maintaining this range ensures that the formulation is safe and effective for topical use.

Spreadability Evaluation

This parameter refers to the ease with which the gel spreads over the skin. It is assessed by evaluating the "Slip" and "Drag" characteristics, which are indicative of the formulation's application properties.

Droplet Size Analysis

Droplet size is crucial for the stability and effectiveness of nanoemulgels. Dynamic light scattering [DLS] is often used to measure the droplet size and distribution.

Polydispersity Index [PDI]

PDI provides information about the uniformity of droplet size in the formulation. A lower PDI indicates a narrower size distribution, which is essential for consistent performance.

Zeta Potential

Zeta potential helps assess the surface charge of the nanoemulgel, indicating its stability. A high zeta potential indicates good stability, as it prevents aggregation of droplets.

Drug Content

The drug content test determines the total amount of drug in the formulation. This is an essential parameter as higher drug content correlates with minimal loss during manufacturing

Accelerated Stability Testing

To assess the long-term stability of nanoemulgels, accelerated stability tests are conducted in compliance with ICH guidelines. These studies typically involve storing formulations at temperatures such as 37°C ± 2°C, 45°C ± 2°C, and 60°C ± 2°C for three months, with periodic analysis of drug content and other quality parameters.

Rheological Characteristics

Rheological studies measure the flow and deformation behaviors of the nanoemulgel when subjected to external forces. This is essential for evaluating the spreadability, drug release, and skin permeation. Rheological properties are evaluated using instruments like Brookfield viscometers and rheometers. The shear-thinning behavior of a formulation, for instance, improves its spreadability and skin permeation.

Applications of nanoemulgels: Curcumin Nanoemulgel: W. Soliman et al. [2021] developed a curcumin-loaded nanoemulgel to improve the bioavailability and skin penetration of curcumin, a poorly water-soluble drug. The formulation exhibited enhanced skin penetration, superior anti-inflammatory effects, and steady transdermal drug release, outperforming traditional curcumin gels.

Tocotrienol-Rich Naringenin Nanoemulgel: E. Yeo et al. [2021] formulated a nanoemulgel to treat chronic wounds in diabetic patients. The formulation showed sustained release over 24 hours, offering more controlled drug release compared to nanoemulsions without polymer coverage. Finasteride Nanoemulgel for Male Pattern Baldness: D. Upadhyay et al. [2020] developed a finasteride-loaded nanoemulgel to improve drug permeability through the skin. The formulation led to significant hair growth and enhanced hair thickness compared to the testosterone-treated group.[64] for Patents on Nano-emulgel Formulations go through table 4.

CONCLUSION

Nanoemulsions represent a non-equilibrium, optically clear, thermodynamically stable, and metastable dispersion of nano-sized particles characterized by a defined surface tension, which is generated through specific shear forces. These dispersions consist of a suitable oil combined with a precise blend of surfactants and co-surfactants, enabling them to solubilize significant amounts of hydrophobic pharmaceuticals. The formation of nanoemulsions can be achieved through various techniques, including the use of homogenizers, low-energy emulsification, and phase inversion methods. Furthermore, there exists considerable debate regarding the optimal approach for preparing nanoemulsions, although it has been demonstrated that they can be effectively formulated using a low-energy emulsification process in conjunction with high shear homogenization. Additionally, nanoemulgel, also referred to as hydrogel-thickened nanoemulsion [HTN], exhibits an increase in viscosity relative to standard nanoemulsions. The stability of a nanoemulsion formulation is further improved by the incorporation of nanoemulgel. It reduces surface and interfacial tension, which in turn leads to an increase in the viscosity of the water-based phase.

ABSTRACT

Shoulder stiffness, often from adhesive capsulitis, limits ROM, causes pain, and impacts daily life. Maitland and Mulligan mobilizations help relieve pain and improve function, but their short-term effects remain underexplored. This study compares their immediate impact on pain, ROM, and function in shoulder stiffness patients. The aim of the study is to determine the short-term effects of Mobilization technique on thepain, range of motion and functional caliber of patients with shoulder stiffness. An experimental study recruited 30 subjects with shoulder stiffness who met the inclusion criteria and provided consent. They were divided into two groups [15 each]: Group A received Maitland, and Group B received Mulligan, both with a conservative protocol for three days. Pain [NPRS], ROM [goniometer], and functional scales [SPADI, QUICK DASH, SST, Constant Murley] were assessed pre- and post-intervention. Pre- and post-comparisons within groups were analysed using the Paired t-test or Wilcoxon Sign Rank Test. NPRS showed high significance [P = 0.001] in both groups. ROM in flexion was significant for Group A [P = 0.03], and abduction was significant in both. SST was significant for Group B [P = 0.006], while SPADI and Quick DASH showed high significance in both groups. Constant Murley was significant for Group B [P = 0.04]. Between-group differences were analysed using the independent t-test or Mann-Whitney U test, showing no statistical significance [P < 0.05] for NPRS, ROM [flexion, abduction], SST, SPADI, Quick DASH, and Constant Murley. Both manual techniques effectively reduced pain, improved ROM, and decreased disability in shoulder stiffness. Maitland showed greater pain

reduction, while Mulligan improved ROM and functional independence. No significant differences were found between groups.

Keywords: shoulder stiffness, mobilization, Maitland technique, mulligan technique, NPRS, Range of motion, SPADI, SST, Quick dash and Constant Murley

INTRODUCTION

The most movable articulation of the appendicular skeleton is, in fact, the shoulder joint, also referred to as the glenohumeral joint [1]. The small glenoid cavity and loose joint capsule, which provide a broad range of motion, are principally responsible for this remarkable mobility [1].But stability suffers as a result of this increased motion, leaving the shoulder more vulnerable to dysfunctions and injuries [1]. In anatomical and biomechanical investigations, this equilibrium between mobility and stability is well acknowledged [2]. The ISAKOS Upper Extremity Committee members met in Amsterdam in May 2014 to develop a consensus statement on the definition, categorisation, and management of stiff shoulder. They suggested using the term "Stiff Shoulder" to refer to patients who exhibit pain and limited range of motion [3]. There are a number of primary and secondary aetiologies for shoulder stiffness. Idiopathic AC is most likely the cause of primary shoulder stiffness, while trauma, fracture, extended immobilisation, or surgical procedures are most likely the subsequent reasons. One of the most common complaints pertaining to the shoulder joint is shoulder discomfort [4]. Although stiffness is frequently a side effect of pain, it can also be directly brought on by capsular tightening and GH joint capsular volume reduction [4]. Many patients come in with shoulder discomfort that causes "stiffness" by limiting active movement, either by muscular guarding or pain inhibition [5].

Restricted active and passive motions at the shoulder joint are indicative of shoulder stiffness. Fibrosis frequently causes this disease, which leads in contracture of the joint capsule and associated ligaments [6]. Most people with shoulder stiffness are between the ages of 40 and 80 [7]. Although some data indicates that women are more likely than men to get adhesive capsulitis, the proportion of females to males fluctuates. In one research, for example, 69% of the 1,377 patients were female, meaning that the ratio was almost 2.2:1 [8]. Diabetics are far more likely to experience shoulder stiffness [9]. Compared to the general population, patients with established diabetes mellitus [DM] are more likely to experience primary and post-surgical shoulder stiffness. According to a recent meta-analysis, the mean prevalence of diabetes mellitus in a group with shoulder stiffness was 30%, while the total mean prevalence of idiopathic shoulder stiffness in individuals with DM was 13.4% [10]. Given that a diagnosis of shoulder stiffness may be the initial indicator of a diabetic disease, this implies that patients with shoulder stiffness should be evaluated to rule out DM [9].

Research has shown that racial predisposition and genetic variables have a role in the development of adhesive capsulitis, often known as frozen shoulder. With results like a 42% heritability rate in monozygotic twins, studies point to a genetic propensity [11]. Idiopathic adhesive capsulitis is also influenced by race; for example, studies show that those who were born in the British Isles or have British Isles heritage are more likely to get it. Additionally, research indicates that Asian ethnic patients are more likely to be at risk, with an adjusted odds ratio of 3.6 [11]. The shoulder is essential for upper arm function, enabling movement and control of the forearm. Daily tasks like reaching the back or combing hair rely on its mobility. A stiff shoulder can hinder these activities, so various treatments focus on restoring function[12]. A thorough exam identifies fibrosis, diagnoses shoulder stiffness, and detects related conditions like diabetes[13]. The pathoanatomical effects of the main trauma, pathological reaction, and subsequent insult are the cause of the stiff shoulder. Although the intensity and aetiology of shoulder stiffness vary widely, it is frequently seen in clinical practice [6].

Physiotherapy evaluation identifies the cause of shoulder stiffness to guide treatment. Assessing pain versus stiffness helps determine the best approach. Evidence-based strategies and structured algorithms enhance effective,

personalized care [14]. Treatment should focus on reducing acute pain and inflammation and halting future soft tissue shortening. Restoring function to attain pain-free range of motion is the most common therapeutic objective of therapists, but treatment philosophies differ greatly [15]. A possible explanation for this might be the lack of objective clinical comparisons of shoulder stiffness treatments [15]. Stiffness may also be caused by the manual therapy approach, which evolved from a number of evaluation and treatment methods. Consequently, a variety of therapies are commonly employed to treat stiff shoulders, with manual therapy being suggested as a potentially beneficial treatment [15].

Manual therapy refers to a skilful passive movement used by doctors to target various anatomical regions directly or indirectly in an effort to improve a patient's suffering [16]. Mobilisation and manipulation techniques are among the several therapies that have been recommended to improve upper extremity functional activity and restore a pain-free condition [16]. Research has shown ample evidence for Mulligan's manual treatment method, which is called Mobilisation with Movement [MWM]. In order to eradicate pain and regain function, Mulligan's MWM combines mobilisation forces with active movement. Numerous MSK disorders have been treated with this method with encouraging outcomes [17].

The Mulligan Concept's basic idea is that the physiotherapist can advance therapy after a passive glide or joint mobilisation is pain-free. Once the glide has been performed, the patient is asked to do a previously provocative movement, and it should be seen that the movement improves in range, discomfort, or both [18]. While the therapist maintains the proper mobilisation, the patient repeats the previously limited and/or painful action. When using this method, often referred to as mobilisation with movement [MWM], the PILL reaction is noted for: P-painless, I-immediate outcome, and LL-long-lasting [18]. The Maitland idea is defined by the IMTA as a method of diagnosing, treating, and evaluating neuromusculoskeletal disorders via manipulative physiotherapy [19].By repeatedly activating mechanoreceptors that block nociceptive pathways at the brain stem or spinal cord levels, the oscillations may have an inhibitory impact on the perception of painful stimuli. By transferring the synovial fluid, these motions aid in enhancing the nourishment of the cartilage [19].

The idea behind Maitland mobilisation is oscillatory motions done at different intensities to increase joint mobility and reduce discomfort. The neurophysiological effects of the Maitland mobilisation method on mechanoreceptors and its capacity to stretch the capsular tissue under regulated conditions are responsible for its effectiveness [20]. Grade II mobilisation promotes mechanical effects on the capsular tissue while operating within the painless range when applied precisely to appropriate moderate tissue irritation [20]. Combining Maitland mobilisation with conventional physiotherapy may be beneficial, especially for addressing intermediate degrees of tissue irritation. By combining standard physiotherapy with Maitland mobilisation, this combination technique addresses the neurophysiological and mechanical aspects of this agonising condition, reducing pain and fostering functional recovery in adhesive capsulitis [20]. The Maitland approach treats stiffness and mechanical pain by using passive and auxiliary mobilisations of the spine. In order to increase range of motion and reduce pain, the Maitland mobilisation is graded as follows:[21]

- **Grade I:** Low amplitude at the start of ROM.
- **Grade II:** Moderate amplitude from start to mid-ROM.
- **Grade III:** High amplitude from mid-ROM to restriction.
- **Grade IV:** Low amplitude at the restricted joint area.

So, the purpose of the study is to determine the effect of mobilization technique on pain, functional range and functional Caliber of the individual to do activity of daily living and improve functional ability in individual with shoulder stiffness.

MATERIALS AND METHODOLOGY

A study was conducted on 30 individuals with shoulder stiffness in Ahmedabad, Gujarat, with informed consent. Participants aged 40-60 were included if they had shoulder pain for at least three months, limited ROM, adhesive capsulitis, diabetes, post-operative stiffness, or prolonged immobilization. Those with severe trauma, multiple fractures, rotator cuff tears, or calcific tendinitis were excluded. Pain and functional disability were assessed using NPRS, ROM, SPADI, Quick DASH, SST, and Constant Murley scores. After selecting 30 eligible individuals, they were divided into two groups for mobilization therapy. Group A [15 individuals] received Maitland mobilization with conventional therapy, while Group B [15 individuals] received Mulligan mobilization with conventional therapy. The intervention was administered for three days, with 15 repetitions in three sets per session, allowing a one-minute rest between sets. Each session lasted 30 minutes.

Group A: Maitland mobilization [27]
The glenohumeral caudal glide, glenohumeral caudal glide progression, and glenohumeral posterior and anterior glide were among the glides demonstrated. For 30 seconds, passive oscillatory motions were executed at a rate of two to three glides per second, with each glide lasting three sets.

Conservative protocol: hot fomentation, Codman's exercise, Wand exercise, towel stretch, capsular stretches and pectorals minor stretching [27], [30].

Group B: Mulligan mobilization [28],[29]
The MWM technique for shoulder flexion involved positioning the patient comfortably in a sitting posture with a belt on the humeral head. The therapist applied a glide while providing counterpressure to the scapula, maintaining a pain-free range during active shoulder movements. This was repeated for 3 sets of 15 reps with a 1-minute break between sets. For external rotation, the patient lay with a towel under the scapula, holding a stick with both hands to assist movement. The therapist stabilized the humeral head and applied a glide backward and outward without discomfort. This was performed for 3 sets of 15 reps, with a 30-second rest between sets.

Conservative protocol: hot fomentation, Codman's exercise, Wand exercise, towel stretch, capsular stretches and pectorals minor stretching [27], [30].

RESULT

Data analysis was conducted using SPSS 22.0, with significance set at $p<0.05$. Descriptive statistics assessed mean and standard deviation, while normality was checked via the Shapiro-Wilk test. Group differences were analysed using the Independent T-test or Mann-Whitney U test, and pre-post comparisons were done using the Paired T-test or Wilcoxon Signed-Rank test.

DISCUSSION

This intervention-based study aimed to evaluate the efficacy of joint manual mobilization techniques in managing shoulder stiffness, focusing on pain, range of motion, and functional capacity. Specifically, the study sought to determine the short-term effects of mobilization techniques on these parameters. A total of 30 individuals, aged between 40 and 60 years, participated in the study, with 15 individuals in each group. Group A underwent Maitland mobilization combined with conventional exercises, while Group B received Mulligan mobilization along with a conservative protocol, each session lasting 45 minutes. Pre- and post-intervention assessments were conducted to measure pain [NPRS], range of motion, and functional performance using SST, SPADI, Quick DASH, and Constant Murley scales.

When the outcome measures were analyzed, both groups showed notable improvements. Reduced pain and disability were shown by the significant decrease in pre-post intervention scores on the Quick DASH, SPADI, and NPRS. The results of the SST, Constant Murley Scale, and range of motion all showed a significant improvement at the same time, indicating improved mobility and functional ability. Shoulder stiffness is a painful, restricted glenohumeral ROM condition that may occur spontaneously or from secondary causes. It limits functional movement due to faulty joint play, impairing physiologic and accessory motions needed for optimal shoulder function and ADLs.

Statistical analysis of the data in pre-post intervention of NPRS values illustrated differences though both groups have significantly reduced pain scores, the difference was found in Group A, in between group comparison. Both the groups showed reduction in pain scores suggesting that mobilization reduces pain owing to neurophysiologic effect on the stimulation of peripheral mechanoreceptors and the inhibition of nociceptors [17]. Maitland mobilization benefits pain relief by triggering central and local physiological processes. Small-amplitude oscillations activate proprioceptors and mechanoreceptors, blocking pain perception via spinal pathways. These non-stretch actions improve ROM and reduce discomfort. Additionally, systematic oscillations enhance vascular perfusion, preventing ischemia, enema, and fibrosis. Mobilization aids fluid flow by creating a pressure gradient, improving venous drainage, reducing joint effusion, and easing pain. Research suggests mobilization induces hypoalgesia.

The improved pain score in group B is believed to be attained through the correction of the positional fault present at the joint surface, which when corrected with an appropriate sustained glide, instantly reduces pain and restores necessary physiologic and accessory movements at joint surface. The Maitland Mobilization group had statistically significant scores, while both Mobilization groups showed a clinically meaningful increase in range of motion. One possible explanation for this is that graded mobilizations at the start of the available range of motion treat pain by activating neural structures, while graded mobilizations at the end of the available range of motion cause the connective tissue to elongate. The rhythmic motions during Maitland mobilization are thought to have mechanical effects, including increased fiber glide, collagen realignment, and adhesion breakage, which aid in restoring normal mobility, according to research. A study by A. Joseph Threkeld suggests mobility improves by restoring interstitial fluid in connective tissues, normalizing frictional forces. Mulligan mobilization in Group B enhanced ROM by correcting joint malalignment, improving contact surface congruency, and aiding ADLs. Pain relief is linked to mobilization's neurophysiologic effects, while prolonged glides enhance circulation and nutrition. However, the comparison between Groups A and B remains statistically insignificant.

The study found a significant reduction in functional impairment among individuals with shoulder stiffness. Both mobilization groups showed improvement in outcome measures, with patient- and therapist-reported assessments minimizing errors. Pain relief and increased ROM likely enhanced functional independence, while accurate evaluation and treatment of pain, ROM, strength, and ADLs contributed to reduced impairment. Thus, this study proves that both the mobilization techniques were effective in reducing pain and improve range of motion, functional ability, but Maitland mobilization group showed more significant reduction of pain whereas mulligan mobilization group showed more significant improvement in range of motion and functional ability.

CONCLUSION

This study comes to the conclusion that by lowering discomfort, increasing range of motion, and improving functional capacity, both Maitland and Mulligan mobilisation methods are useful in treating shoulder stiffness. The Maitland mobilisation approach was shown to be more successful in lowering discomfort, whereas the Mulligan mobilisation technique produced larger increases in range of motion and functional capacity, even though both groups demonstrated considerable improvements.

Limitation of Study

1. Larger sample size
2. Long term follow-ups
3. Unequal gender ratio

Future Recommendations

1. Consideration of strength component

ABSTRACT

Dipeptidyl Peptidase-4 inhibitors, commonly known as gliptins, represent a class of oral hypoglycemic agents used in the management of type 2 diabetes. This research investigates the comparative inhibitory effects of various gliptins against DPP-4 enzyme using molecular docking analysis. The study employed molecular docking simulations to evaluate the binding affinities and interactions of different Gliptins (Sitagliptin, Omarigliptin, Teneligliptin, Gemigliptin, Gosogliptin, Evogliptin) with the DPP-4 enzyme. The results revealed varying degree of binding affinities and interaction among the gliptins showing the most promising results and exhibiting the strongest inhibitory potential. The study provides insights into the molecular mechanism underlying the inhibitory effects of Gliptins and may aid in the design and development of more potent DPP-4 inhibitors for the Treatment of Type -2 Diabetes. Molecular Docking was performed using PyRxSoftware to evaluate the binding affinities and interaction among the Gliptins. From the molecular docking studies, it was found that Gemigliptin, Omagrigliptin, Teneligliptin have better binding affinity at the active site of DPP-4 receptor.

Keywords: Omarigliptin, DPP-4 enzyme, binding affinities and interaction, molecular docking, hypoglycemic agents

INTRODUCTION

Diabetes mellitus is a chronic disease characterized by insufficient insulin production or ineffective insulin utilization, leading to elevated blood glucose levels. Insulin, secreted by the pancreas, regulates glucose transport into cells for energy. Diabetes increases the risk of cardiovascular complications and affects multiple organs.

Prevalence and Demographics

- Type 2 diabetes accounts for 87-91% of cases in high – income countries, while type 2 comprises 7-12%
- By 2045, diabetes prevalence is projected to rise significantly, with gender distribution showing slightly higher prevalence in man

Types of Diabetes

Type1 Diabetes: Insulin – dependent, often diagnosed in childhood or adolescence, caused by autoimmune destruction of pancreatic beta cells.

Type 2 Diabetes: Characterized by insulin resistance and impaired insulin secretion, more common in adults and associated with lifestyle factors.

Symptoms

- Increased thirst and urination
- Blurred Vision
- Fatigue
- Unintended weight loss

DPP-4 Inhibitors (Gliptins)

DPP-4 inhibitors are oral antidiabetic drugs that manage type 2 diabetes by inhibiting the DPP-4 enzyme, which degrades incretin hormones (GLP-1, GLP) responsible for stimulating insulin secretion. These drugs improve glycemic control without causing significant hypoglycemia.

Approved Gliptins

1. Sitagliptin
2. Saxagliptin
3. Linagliptin
4. Alogliptin
5. Vildagliptin (approved in Europe)

Mechanism of Action: DPP-4 inhibitors prolong the action of incretin hormones, enhancing insulin secretion and suppressing glucagon release in a glucose- dependent manner. DPP-4 is a ubiquitous enzyme that acts on incretin hormone mainly GLP-1 (Glucagon like peptide -1) and GLP (gastric inhibitory peptide), which maintain glucose homeostasis by increasing insulin secretion and decreasing glucagon secretion. These in cretins are released within minutes of food intake, and DPP-4 degrades these hormones immediately due to their short half- life. By inhibiting the DPP-4 enzyme, DPP-4 inhibition increases the level of GLP-1 and GLP, which in turn increases beta cell insulin secretion in the pancreas, thereby reducing postprandial and fasting hyperglycemia.

EXPERIMENTAL METHODOLOGY

Molecular Docking: PyRx software was used to perform docking simulations of gliptin with the DPP-4 enzyme.

Analysis: Binding affinities, bond lengths and interaction types were evaluated to compare inhibitory potential.

Bio via discovery Studio: BIOVIA Discovery Studio Visualizer is a free, feature-rich molecular modelling application for viewing, sharing and analyzing protein and small molecule data.
Experts and their colleagues can seamlessly and efficiently exchange results, without loss of either time or scientific information. BIOVIA modelling and simulation software allows scientists to perform computations of chemical, biological and materials properties; to simulate, visualize and analyze chemical and biological systems; and to communicate the results to other scientists.

Data Preparation: Import molecular structures, such as proteins, ligands, or small molecules, into the software.

Visualization: Explore and visualize molecular structures in 3D to understand their spatial arrangements and interactions.

Structure Optimization: Use tools for energy minimization and structure optimization to refine molecular geometries and remove any steric clashes.

Docking Studies: Perform docking simulations to predict how ligands bind to protein targets and identify potential binding poses and interactions.

Virtual Screening: Screen libraries of compounds to identify potential drug candidates based on their predicted binding affinity and other properties.

Analysis: Analyze results from docking studies and virtual screening to prioritize compounds for further experimental testing.

Visualization and Reporting: Visualize results and generate reports to communicate findings and conclusions.
These steps can vary depending on the specific goals and workflows of the research or project being conducted. Discovery Studio offers a range of tools and functionalities to support various aspects of molecular modelling and drug discovery.

Docking Process: For molecular docking, PyRx and Discovery Studio (Biovia) was utilized. First, ligands and receptors were formatted into pdbqt. For molecular Docking, these pdbqt files were then utilized. The grid box's dimensions were determined based on the structure's requirements, and other docking parameters were defined. Both ligands and receptors were successfully docked, and an excel sheet was used to interpret each binding score. The excel sheet was used to individually interpret each ligand with the highest binding score, and discovery studio.

RESULT and DISCUSSION

Ligands of interest were docked by using Auto dock Vina PyRx software and the data of six compounds showed good binding affinity. The result is displayed in the table:1 given below

Sitagliptin (Figure 1)
Below figure shows that trifluoro phenyl ring forms halogen bond with GLN B: 731 at a distance of 3.51 , Pi-Pi T shaped bond with HIS B: 757 and HIS B:754 at a distance of 5.24 and a conventional hydrogen bond with GLN B: 761 at a distance of 3.56

Teneligliptin (Figure 2).
Below figure 2 shows that thiazolidine ring forms Pi-sulfur bond and carbon hydrogen bond with TYR B: 585 at a distance of 5.84, conventional hydrogen bond with GLN B: 553 at a distance of 3.77. Pyrazole ring forms conventional Pi-alkyl bond with ARG B: 358 at a distance of 5.14.

Omarigliptin (Figure 3).
Below figure shows that pyrazole ring forms Pi-anion bond with ASP B:545 at distance of and carbon hydrogen bond with LYS B: 554 at a distance of 5.84. Sulfonamide group forms conventional hydrogen bond with ARG B: 560 at a distance of 3.77. Di-fluorophenyl ring forms conventional Pi-alkyl bond with B:8O 3802S at a distance of 5.14.

Gemigliptin (Figure 4).
Above figure shows that fluorine of trifluoromethyl forms halogen bonds with ILE B: 405 at distance of 2.83 and VAL B: 404 at a distance of 3.22. Fluorine of trifluoromethyl of piperazine ring forms conventional hydrogen bonds with PHE B: 357 at a distance of 3.38 and ARG B : 358 at a distance of 3.27

Gosogliptin (Figure 5).
Above figure shows that piperazine ring forms conventional hydrogen bond with ASN A: 562 at a distance of 3.36 and carbon hydrogen bond with TYR A: 752 at a distance of 3.54 .The pyrimidine ring forms water hydrogen bond with HOH A: 941 at a distance of 3.40

Evogliptin (Figure 6).
Above figure shows that the trifluoro phenyl ring forms halogen bonds with ILE A: 107 and PRO A: 109 at a distance of 3.10 and 3.80and forms a carbon hydrogen bond with PRO A: 159 at a distance of 3.37

Physiochemical Parameters(Tabe:2)

CONCLUSION

The docking study results show that all six tested compounds demonstrated good binding affinity with target profile, as indicated by their negative binding affinity values. Among them Gemigliptin exhibits the strongest binding affinity (-8.8), followed closely by Omarigliptin (-8.7), while Evogliptin showed the weakest binding affinity (-6.8) .The standard drug Sitagliptin has a binding affinity of -8.3 ,which was matched by several other compounds, suggesting that some tested ligands may be effective than the standard drug in binding to target protein. The comparative analysis of Sitagliptin Tenegliptin, Gemigliptin, Omari gliptin, and Gosogliptin reveals that all five DPP-4 inhibitors share several favorable drugs- like properties like High GI absorption and good solubility, indicating strong oral bioavailability potential. All compounds comply with major drug- likeness rule (Lipinski Veber, and Egan) with no PAINS alerts, supporting their solubility as oral therapeutics. Blood brain barrier permeability is observed from Sitagliptin, and Teneligliptin only, which may influence their central side effects profile. Overall, these DPP-4 inhibitors exhibit oral drug -like profiles with slight variations that may affect their clinical use and safety

ABSTRACT

Probiotics are best described as live microorganisms that, in some way, positively impact the body. Probiotics are known to assist in cancer treatment. Researchers suggest that probiotics might potentiate the effects of standard treatments and help reduce side effects caused by the therapies. Probiotics affect the gut microbiota that is responsible for the gut region's barrier, has an effect on the body's immunity, and, therefore, affects the development of the tumor and how the body responds to the treatment. This review explores the mechanisms of probiotics to treat cancer, including modulating the gut microbiota, improving chemotherapy, and mitigating gastrointestinal toxicity. Some of the species, including *Bifidobacterium* and *Lactobacillus*, have been shown in preclinical and clinical studies to enhance host immune surveillance and suppress tumor growth. Probiotics can also aid mucosal barrier maintenance and dysbiosis induced by anticancer treatments.

Keywords : Probiotics, apoptosis, carcinogenesis, Anticancer effect, mutations, immunity.

INTRODUCTION

Globally, cancer ranks as the second most common cause of death. The random intracellular accumulation of spontaneous mutations during DNA replication leads to the development of cancer. Environmental exposure and lifestyle choices can also have a major impact on cancer. Cancer cells are characterized by their unchecked cell division and resistance to apoptosis. Since the precise origins of the majority of cancer types are unknown, there is no one treatment that works for all cases of the disease; however, it is recognized that a variety of physiological and metabolic abnormalities in the cell cause cancer to grow. Every type of cancer has distinct important targets, including proteins, enzymes, immunological regulatory signals, and apoptotic signals. One can assess therapeutic medications that may be useful in the fight against any given malignancy based on these targets. The ability to restore cells to their initial state once treatment is administered to cancer cells determines how effective cancer prevention is. [1]

Probiotics

There are more than 100 trillion bacteria in the human digestive tract that are important for keeping the digestive system in balance. The intestinal microbiota is essential for bolstering the intestinal immune system and controlling host metabolism. In recent years, several researchers have been interested in probiotics and other helpful microbes. Both the World Health Organisation and the United Nations Food and Agriculture Organisation concur that probiotics are beneficial to human health when taken in moderation. [2] The Latin term pro bios, which means "for life," is where the word "probiotic" originates, and the lactic acid fermentation products' subsequent positive health effects are based on an old principle. Élie Metchnikoff, a scientist who won the Nobel Prize, came up with the notion in the first place. Numerous significant research on the role and function of probiotic microorganisms were co-authored by him. He thinks that the human colon's lactic acid bacteria may be able to extend life. Probiotics are defined as "live microorganisms which, when administered in adequate amounts, confer a health benefit on the host" in current terminology. These are mostly Lactobacilli and Bifidobacteria, with a few species of Streptococcus and Enterococcus. [3] The advantages of probiotics include strengthening the host immune system, enhancing the function of the epithelial barrier, and the synthesis of antibiotic chemicals or metabolites like lactic acid for suppressing the growth of pathogenic bacteria. Though there exist investigations which revealed potential uses of probiotics for preventing and treating cancer through the mechanism of immune modulation, microbiota manipulation, suppression of bacterial translocation, increased gut barrier integrity, and anti-inflammatory and antipathogenic effect which would suppress tumour growth and metastasis, another indirect benefit of probiotics is the fortification of the host gut microbiome. A main cause of stomach cancer, Helicobacter pylori, was antagonistically active against some lactobacilli strains (16–18). The clear association between the acquisition of cervical cancer and persistent high-risk human papillomavirus (HPV) infection is established today. [4] Theorganisms must possess the following characteristics to serve as a probiotic. [5] Bile salt hydrolase can be metabolized by bile acid tolerance, adhesion to epithelial and mucosal surfaces for the purpose of keeping the immune system under control, antibacterial effect, and support for the normal flora of the intestines, especially for the patients who are on antibiotics.

Relation between Probiotics and Cancer Treatment

In human cancer cell lines and cells, the probiotics were found to exert antiproliferative or proapoptotic activities; the highest examined were the colon and gastric cancer cells (Figure 1). In the research of Lee et al., the cytoplasmic extracts of Bifidobacterium longum, Lactobacillus acidophilus, and Lactobacillus casei showed significant anticancer activities toward specific cancer cell lines. Russo et al. and Orlando et al. established that the cytoplasmic extracts of Lactobacillus rhamnosus strain GG (LGG) exert antiproliferative activity toward human colonic and stomach cancer cells. However, three human colon cancer cell lines, HT-29, SW 480, and Caco-2, were reduced in proliferation through Bifidobacterium adolescentis SPM0212, another probiotic supplement. [4] Changes in the skin microbiota are seen among the spectrum of cutaneous neoplasms and accompany the onset of carcinogenesis. The association

between S. aureus infection and the degree of cutaneous T-cell lymphoma, where it might be triggered by a Staphylococcal superantigen during carcinogenesis, is one such example. However, a healthy microbiome can inhibit carcinogenesis through the regulation of the immune system and inflammation by initiating anticancer or immune surveillance programs. Oral consumption of lipoteichoic acid from lactobacilli, for instance, was linked with lowered risk for UV exposure and skin malignancies. Recently, it was discovered that certain S. epidermis strains released a nucleobase compound that specifically prevented the formation of tumours. [5]

Mechanisms of probiotics for cancer therapy

The immune system is essential for stopping and managing the development and spread of tumours. Antigen-presenting cells (APC), diverse T-cell populations, B-cells, natural killer cells, and dendritic cells are among the immune system components that are typically activated during invasion or mutation. According to experimental studies, probiotics have anticancer effects by influencing the activity of cancer cells by influencing macrophage immune responses. T-cells and natural killer cells.

Modulation in gut microbiota

In order to preserve eubiosis, or homeostasis. Well-balanced and diversified gut flora are needed. An imbalance within the gut microbiota can cause a condition of dysbiosis, where there are too few good bacteria and too many pathogens. [7, 8] Dysbiosis can increase the risk for colorectal cancer through the production of carcinogenic compounds and the production of ongoing inflammation. Comparison of faecal samples of patients with colorectal cancer and healthy controls was done by Sobhani et al. [9] Bacteroides and Prevotella were much higher in the colorectal cancer group, according to their study. For bacteria belonging to the genera Eubacteria, Fusobacteria, Prevotella, Proteobacteria, and Bacteroides, a number of Lactobacillus species were pre-genotoxic and transmitted in smaller quantities to the intestinal environment. The intestinal microbiota has been linked to the gastrointestinal tract's development.

By changing intracellular signal transmission and attaching to certain cell surface receptors, bacterial compounds that are genotoxic and toxic can also cause mutations in cancers [7]. Probiotics have the ability to competitively exclude harmful bacteria. Because probiotics may stick to the gut mucosa and compete for resources, they may be able to competitively exclude harmful microorganisms. The amount of nutrients available to the distal colon is restricted. Probiotics thrive at the expense of and outcompete other intestinal microorganisms for resources. Pathogenic microorganisms and probiotic strains compete to produce continuous, thin films known as biofilms in order to colonise and cling to biological membranes. [8]Through the tightening of the intestinal barrier, the prevention of the formation of infections, and the inhibition of the metabolism of carcinogen chemicals, the results of some clinical trial studies confirmed the positive actions of the probiotics on the composition of the gut microbiota and, thus, on the host. Ohara et al. examined the intestinal flora of the colorectal cancer patients and the healthy subjects, and they presented the possibility of the use of the probiotics for the prevention of colorectal carcinogenesis. [10] The use of the probiotics resulted in an increased production of the isobutyric acid and the short-chain fatty acids, an inhibition of the formation of the putrefactin within the faeces, and a decreased total number of the Clostridium perfringens, an indicator of acidosis. Probiotic therapy reduced anastomotic leak risk markedly, infections, and the requirement for post-operative oxygenation support. In colorectal cancer patients, the gut environment worsened compared with normal controls; probiotics enhanced the gut ecology. These results lend support for the possibility that probiotics can give some defense for colorectal cancer. [9]

Producing Anti-Cancer Compounds

The role of short-chain fatty acids (SCFAs) in intestinal and systemwide immune regulation. Non-digestible carbohydrates (NDCs), indigestible dietary fibre, and resistant starch (RS) are fermented by the gut microbiota for the production of SCFAs. SCFAs manage the integrity of the gut barrier by inducing the release of tight junction expression, antimicrobial peptides, mucin (MUC2), and interleukin-18 (IL-18) from the intestinal epithelium. In addition, SCFAs regulate the function of the T cell by suppressing histone deacetylase (HDAC), and affects the regulation of nuclear factors (nuclear factor-κB; NF κB), Olfr78 receptor signal, and G-protein-coupled receptors

(GPR41, GPR43, and GPR109A). SCFAs exert an immense effect on the migratory capacity of neutrophils into the region of inflammation and theiracity for phagocytosis. Besides, SCFAs inhibit the synthesis of proinflammatory cytokines (such as IL-6, IL-8, IL-1β, and TNFα) by the macrophages in the gut and induce the synthesis of IgA in the gut by the B cells.

SCFAs affect the development of the Treg cells and the production of interleukin-10 (IL-10). SCFAs' T cell differentiation occurs both through their immediate action and through their control over dendritic cells (DCs). SCFAs largely regulate the production of Treg, Th1, and Th17 under various cytokine conditions. Through the induction of apoptosis and the suppression of proliferation of tumour cells, SCFAs prevent the development of cancer. [11]Via fermentation of resistant starch (RS), indigestible dietary fibre, or nondigestible carbohydrates (NDCs), the gut microbiota synthesizes SCFAs. Via the stimulation of the intestinal epithelial cells for the production of interleukin-18 (IL-18), mucin (MUC2), antimicrobial peptides, and tight junction expression . SCFAs are controlled by the function of the intestinal barrier. SCFAs also affect the regulation of the nuclear factors (NF-κB; nuclear factor-κB) via inhibition of the histone deacetylase (HDAC), Olfr78 receptor signalling, and the G-protein-coupled receptors (GPR41, GPR43, and GPR109A). SCFAs are also essential for activating neutrophil phagocytosis and driving them to migrate along the direction of the inflammatory sites. [12]

Inducing Apoptosis

The incidence of cancer formation is governed by the growth and death of cancer cells. They grow more than they die over the period of cancer development.[12] Since the removal of cancer cells would be less brutal and since apoptosis doesn't damage the surrounding cells or cause inflammation, probiotics that can control cell growth and death are of much interest. These cells increase more than they die off along the pathway to cancer formation.[13] Probiotic bacteria like lactic acid bacteria (LAB) can initiate signal transduction via both intrinsic (mitochondria-independent) and extrinsic (dependent upon the death receptor) pathways.

According to in vitro experimental results, probiotics used for their anti-cancer actions work through rendering tumor cells cytotoxic and genotoxic.[14] They evaluated the impact of Lactobacillus casei 01 on 4-nitroquinoline N-oxide (4-NQO) induced colon cancer cell line (HT29) and genotoxicity. Metabolites of Lactobacillus acidophilus 36YL produced the highest cytotoxic impact on colorectal cancer cell lines (HT-29) and human cervical cancer cell lines (HeLa), stated Nami et al. As probiotics showed proapoptotic action versus carcinoma cells in vitro through the use of cell lines. Probiotic courses can be employed as an adjuvant therapy during anticancer chemotherapy.[15].

Extrinsic pathway is activated by stimulation of the FAS ligand-induced death receptor on the cell membrane (e.g., tumour necrosis factor, or TNF). Intrinsic pathway is activated through radiation and chemotherapy. Bak and Bax need to be activated and their sublocalization on the mitochrondria needs to be known for the intrinsic pathway to be activated. Pharmacologic inhibitors or anti-apoptotic Bcl-2 family members, however, suppress it. Lactic acid bacteria can speed up the apoptosis induction by 5-fluorouracil (5-FU), which can induce autophagy-mediated cell death, through the up-regulation of Beclin-1 and GRP78 or Bcl-2 and Bak. LAB can also suppress cancer by repressing NF-KB-dependent gene products controlling proliferation (Cox-2, cyclin D1) and survival (Bcl-2, Bcl-xl). [12].

Altering Metabolic Enzyme Secretion

Certain bacteria inhabiting the human colon can synthesize carcinogenic compounds from the food apart from the naturally produced bile salts. [16] That is because there are some enzymes like nitrate reductase, azoreductase, glucuronidase, and glucosidase available and active. [17] They convert heterocyclic aromatic amines, polycyclic aromatic hydrocarbons, and primary bile acids into active carcinogens and form aglycones, ammonia, cresols, phenols, and N-nitroso compounds. Due to their cytotoxic and genotoxic actions, those metabolites can trigger aberrant cell growth and enhance anti-apoptotic activities within colonocytes, which can promote colorectal cancer. [18] In order to alter the metabolism of the microorganisms and decrease the risk of colorectal cancer, the activity of the enzymes can be altered.

These fecal enzymes can convert the procarcinogens into carcinogens within the environment. When the subjects were fed on the tenth day, the specific activity of the three enzymes of all the participants was significantly decreased due to the Lactobacillus strains. Some species of pathogenic bacteria, for example, Clostridium, Escherichia coli, Eubacterium, and Bacteroides, possess elevated enzyme activity responsible for the synthesis of carcinogenic chemicals. Probiotic microbes, however, can decrease the number of toxic bacteria within the gut microbiota and thus lower the synthesis of the cancer-causing chemicals within the intestine.[20].

Degrading the Carcinogenic Compounds

Certain probiotic bacteria have the ability to attach carcinogens to their cell walls. The cationic exchange between the carcinogens and the peptidoglycan found in the cell walls of certain probiotic microorganisms is thought to be the cause of this. The faeces would then be used to get rid of the germs and harmful substances. Heterocyclic amines and mutagens, such as 2-amino-3,4-dimethylimidazo [4,5-f] quinoline (MeIQ), 2-amino-3 methyl-3H-imidazo [4,5-f] quinoline (MHIQ), 5-phenyl-2-amino-l-methylimidazo [4,5 f] pyridine (PhMIP), and 3-amino-1-methyl 5-h pyrido[4,3-b] indole acetate (TrpP2) have been shown to bind and cause their release in faeces.

According to Rowland and Grasso's in vitro studies on the activity of gut microorganisms (of the genera Lactobacillus, Bifidobacterium, and Streptococcus) towards dimethyl-nitrosamine, the bacteria of the species Lactobacillus were the most active in degrading this chemical. Morotomi and Mutai showed that Lactobacillus casei exhibited a considerable degree of activity in detoxifying carcinogenic heterocyclic amines, despite the fact that the amine was broken down into its precursor, dimethylamine, and other volatile metabolites. They looked into both live and heat-inactivated bacteria, but only live bacteria were found to possess this ability, indicating that live bacteria produce metabolites or start processes that lead to the detoxification of amines. The study found that probiotics can also detoxify mycotoxins, which can lead to cancer. Aflatoxin B(1)-N(7) excreted in the urine was reduced after five weeks of taking probiotic supplements, according to El-Nezami et al. The incidence of colorectal cancer was significantly reduced by guanine, a marker of hepatocyte carcinogenesis, and by taking synbiotics for 12 weeks. [21]

SUMMARY

Probiotics have been demonstrated to have proapoptotic or antiproliferative effects on human cancer cells and cell lines; the most studied of these are gastric and colon cancers. On certain cancer cell lines, research has demonstrated the potent anticancer effects of cytoplasmic extracts of Lactobacillus acidophilus, Bifidobacterium longum, and Lactobacillus casei. Furthermore, the healthy skin microbiome can prevent carcinogenesis by regulating inflammation and the immune system, and certain strains of S. epidermis produce a nucleobase molecule that specifically suppresses tumour growth. Probiotics have anticancer effects by changing the way cancer cells behave and triggering immune responses.Dysbiosis, which is characterised by an increase in pathogens and a decrease in beneficial organisms, predisposes colorectal cancer. Probiotics enhance the composition of the gut microbiota by lowering carcinogenic substances, preventing infections, and improving intestinal barrier function. Short-chain fatty acids change systemic immunity by lowering inflammation and encouraging neutrophil migration. Probiotic bacteria can change how cancer cells grow and die by causing apoptosis. The risk of colorectal cancer may be decreased by altering the enzyme activity of the gut microbiota.

ACKNOWLEDGEMENT

The facilities needed to carry out the aforementioned review were provided by Dr. L. Rathaiah, Chairman of the Vignan Group of Institutions, for which I am truly grateful.

Table 1: Varieties of probiotics applied in cancer therapy[6]

Probiotics strains	Anticancer activity
Lactobacillus casei, Lactobacillus rhamnosus , Lactobacillus reuteri , Lactobacillus acidophilus , Lactobacillus helveticus R389, *Lactobacillus salivarius* CECT5713 , *Lactobacillus gasseri* CECT5714	Reduces the early stage of carcinogenesis, increases breast cell sensitivity to apoptosis, increases IL-10 and decreases IL-6 cytokines, increases anticancer activity in breast cancer, and Increases chemoprotective effect against cancer development.
Lactobacillus Casei, Lactobacillus acidophilus	In colorectal carcinoma cell line (LS 513)there is increase in apoptosis induction
Propionibacterium freudenreichii	Human colon and stomach cancer cell lines die more frequently as a result of the secretion of short-chain fatty acids (SCFA) into the culture media.
L. Salivarious REN	Decreased the oxidative DNA damage that 4-nitroquinoline 1-oxide (4-NOO) caused in oral cancer.
Bifidobacterium longum and *L. acidophilus*	Exhibits antioxidant activity by stopping the peroxidation of 28–48% of linoleic acid.
Bifidobacterium adolescentis SPM0212	Inhibits the growth of three human colon cancer cell lines: Caco-2, SW 480, and HT-29.

Table 2: Cancer type and An iprobiotic component[6]

Cancer type	Probiotics component
Gastric cancer	*Lactobacillus reuteri* PTCC 1655, *Lactobacillus kefiri* P-IF
Colorectal carcinoma	*Bifidobacterium lactis* Bb12, *Lactobacillus rhamnosus* GG, *Bifidobacterium longum, Lactobacillus acidophilus, Enterococcus faecalis, Bacillus natto, Lactobacillus acidophilus.*
Liver cancer	*Lactobacillus rhamnosus LC705, Propionibacterium freudenreichii* subsp. *shermanii*
Cervical cancer	*Lactobacillus acidophilus, Bifidobacterium bifidum*

ABSTRACT

Diferuloylmethane is a natural yellow mixture of polyphenolic compounds extracted from plant Curcuma long (Curcumin) is member of Ginger family. Due to its versatile pharmacological properties it has been widely studies with or without derivatisation. Present work is attempt of preparation of Pyrimidinone and Thiopyrimidinone analogues using ethanol-water as a solvent and Cesium Carbonate as catalyst. Present method allowed to obtained Diferuloylmethane Pyrimidinone and Thiopyrimidinone analogues at room temperature at good to excellent yield.

Kaywords: Diferuloylmethane, Curcumin, Pyrimidinone, Thiopyrimidinone

INTRODUCTION

Nitrogen and Sulphur containing heterocycles have retained the interest of Medicinal organic chemist researchers along the historical development of Drug Chemistry. The presence of heteroatom or atoms results in remarkable change in cyclic structure due to presence of unshared paired of electron and change in electronegativity. Pauling scale of electronegativity for Nitrogen (3.04) and sulphur (2.58) itself explains different bonding and stability behavior of these heteroatom. High electronegativity bless with strong bonding and extra association with hydrogen atoms if present in, and gives overall stable structural geometry. Low electronegativity of Sulphur suffers from lack of association, these change in electronegativity significantly effect on numbers of available building blocks in laboratories.

Literature survey found reports on Diferuloylmethane (Also known as Curcumin) Schiff base analogues for their biological activity. Diferuloylmethane analogues formed iminesformation with thio-semicarbazide and its copper complex exhibits potent antiblood cancer activity [1,2].

MATERIALS AND METHODS

All the compounds used in synthesis were purchase of analytical grade; the melting points of the compounds weredetermined in open head capillary in paraffin bath and are uncorrected. The IR spectra of the compounds were recorded in the region of 4000-400 cm-1 by using KBr pallet on FT-IR Perkin spectrophotometer. H^1NMR spectra were recorded on a DRX-300 Bruker FT-NMR spectrophotometer in *D6*-DMSO. The values of chemical shift are expressed in δ ppm as a unit. All the compounds were checked for purity by thin layer chromatography (TLC).
(1

Experimental Procedure

Diferuloylmethane (**1**; 1mmol; 1 eq.) was taken in round bottom flask consisting 20 ml of aqueous alcohol (20%), to this urea/thiourea (1.5 mmol; 1.5 eq.) was added and allowed to stir at room temperature for 30 minutes for homogenous mixing. Cs_2CO_3 5mol%) was added in one portions. Yellow colour changes initially to dark red and finallydark brown colour observed. Reaction mixture allowed to stir at room temperature and progress of reaction was monitor by TLC. After completion of reaction content pour to 25 ml of ice cold water and acidified with dropwise addition of dil. HCl using *p*H paper. All content set aside without further stirring for 1-2 hours. Thus obtained yellow solid was filter and washed with water, finally recrystallize from ethanol to obtained pure product, as depicted in Scheme 1.

RESULTS AND DISCUSSIONS

Schiff base was first reported in the 19th Century and name after scientist Dr. Hugo Schiff who discovers the reaction [**5**]. Huge research work has been done to improve synthesis of Schiff base in form of productivity, smooth reaction completion with complex molecules, milder solvent-catalyst combination and respect to greener reaction profile. Early 21th Century it observed that efficient product formation depends upon nature of used carbonyl compound. Highly electrophilic carbonyl moiety and strong nucleophilic amines are the best starting material for Schiff base formation reaction. [6] In case of Schiff base synthesis, Diferuloylmethane play's carbonylsubstrate role and being an-alter one. To improve electrophilicity of diferuloylmethane-carbonyl it was logical to search appropriate Lewis acid catalyst. Involvement of Lewis acid helps to eliminate water molecule at final step [6], especially incase of low electrophilic carbonyl compound. Various Lewis acid used as catalyst for synthesis of Schiff base like, $ZnCl_2$ [7], $TiCl_4$ [8], $MgSO_4$-PPTS [9], $Ti(OR)_4$ [10],$MgSO_4$ [11], H_2SO_4 [12],Ruthenium catalyzed [13], $MgSO_4$ [14], $Mg(ClO_4)_2$ [15], $Er(OTf)_3$ [16], P_2O_5/Al_2O_3[17], Lanthanum, Thorium [18] and MCM-41-SO_3H [19].

To investigate proper solvent-catalyst combination series of reactions were carried out. During development of new synthetic protocol focus was remained maintained on avoiding high temperature or reflux reaction condition. A greener reaction pathway has its own significant importance, hence while trial and error method purposefully green solvent and catalyst were explored. Water were taken as solvent and ethanol was added dropwise to know minimum amount of alcohol required to dissolved diferuloylmethane, and found 20% of aqueous alcohol is best combination and used further without any changes. As a model reaction strategy, Diferuloylmethane and urea were chosen as fixed starting materials. Urea was taken as excess to assure complete transformation of diferuloylmethane into product. Another advantage of excess urea was it is water soluble and excess of urea will be easily removed with water work-up procedure.Various used base catalyst are depicted in Table 1. Water and alcohol was taken as solvent hence inorganic bases were taken as best compatible catalytic partners, like bicarbonate, carbonates and hydroxide (Table 1; Entry 1,2,4,5 and 3 respectively). Organic bases were tried for fair comparison with inorganic bases. But as expected organic bases does not found productive with aqueous alcoholic solvent combination. Cesium carbonate (Table 1; Entry 4) emerged as good catalyst with high productivity.

Finally study of effect of substituent on yield of product was done, by derivatisation method. Previously prepared diferuloylmethane analogues were taken as starting material for reaction with Urea and Thiourea. Structures of various synthesized analogues of pyridmidinone/thions are illustrated in Figure 2. It was observed that electron donating functionality elevates yields of product, whereas, electron withdrawing substituent responsible to fall down yields of product. Productivity of unsubstituted diferuloylmethane analogues (3 and 10) found in between these two.

Spectral analysis of sample compound:
As synthetic molecules were known, sample prepared compounds (1) and (9) were scan for analysis and found in agreement with reported data.

4,6-bis((E)-4-hydroxy-3-methoxystyryl)pyrimidin-2(2H)-one (**1**): IR: (KBr) cm^{-1}: 3523 (OH), 3164 (NH), 1630 (C=O), 1563 (C=N), 1363 (C–N). 1H NMR (300 MHz, DMSO-d6): δ 3.74 (3H, s, OCH3),3.79 (3H, s, OCH3)5.88 (1H, s, H-4), 6.34 (2H, d, H-2,6), 6.69 (2H, d, H-1,7), 6.73–7.11 (m, ArH) 13C NMR (75 MHz, DMSO-d6) ppm:56.3 (-OCH3), 56.8 (-OCH3), 111.4 (C-4), 112.3 (ArC), 122.3, 122.8 and 122.9 (ArC and C-2,6), 127.6 ArC-1,1'), 142.6 (C-3), 147.5 and 147.9 (ArC-4,3), 151.1 (CO), 162.4 (N=C).

4,6-bis((E)-4-hydroxy-3-methoxystyryl)pyrimidin-2(1H)-thione (**9**): IR: (KBr) cm^{-1}: 3511 (OH), 3119 (NH), 1577 (C=N), 1361 (C–N), 1270 (C=S); 1H NMR (300 MHz, DMSO-d6): δ 3.71 (3H, s, OCH3), 3.79 (3H, s, OCH3), 5.64 (1H, d, H-6), 6.09 (1H, s, H-4), 6.79-6.82 (2H, d, H-1,2), 6.87 (1H, d, H-7), 6.98–7.16 (6H, m, ArH); 13C NMR (75 MHz, DMSO-d6) ppm: 54.4 (-OCH3), 55.1 (-OCH3), 109.6 (C-4), 120 Chapter 4 118.7 (ArC), 120.3 and 120.4 (ArC and C-6), 127.3-130 (ArC), 135.1 and 138.2 (C-1,7), 152.8 (C-3), 161.9 (N=C), 174.9(S=C).

CONCLUSION

In conclusions, describe method of diferuloylmethane-pyrimidinone / thione analogues by Cesium carbonate catalyzed and 20% of aqueous ethanol method has unique green concern. All chemical component used are environmentally benign. Easy reaction procedure and smoothly conversion of reactant to product are advantages of describe method. At work-up stage, simple filtration and recrystallization to obtained pure product increase importance of describe method.

ACKNOWLEDGEMENTS

The authors are thankful to Principal of Vivekanand Arts, Sardar Dalipsingh Commerce and Science College Chhhatrapati Sambhajinagar for encouragement for this research work and providing all necessary laboratory facilities.

ABSTRACT

Oral squamous cell carcinoma (OSCC) is a common malignancy, particularly in developing countries, where lifestyle and environmental factors contribute to its high incidence. *Enteromorpha Compressa,* a marine macroalga rich in bioactive compounds, has shown antioxidant, anti-inflammatory and antimicrobial potential. Ethanol extraction yields a broad spectrum of phytochemicals, warranting evaluation of its cytotoxic effects on normal (Vero) and OralSquamous cell carcinoma (KB) cell lines to assess both safety and therapeutic potential. An in vitro study was conducted using the KBand the Vero cell lines. The test drug, Ethanolic extract of *E. Compressa,* was tested for cytotoxic potential using the MTT (3-- [4,5-dimethylthiazol-2-yl] - 2,5-diphenyltetrazolium bromide) assay. The study

was conducted using the MTT assay to determine the cytotoxicity of the plant extract against the oral cancer cell line by determining the IC_{50} values at the end of 24 hours. At the end of 24 hrs IC_{50} value was calculated for the *E. Compressa* Ethanolic extract against the Vero cell line and the KB cell line. It was noted that in the Vero cell line at100µg/ml, more than 65% cells were viable, proving the extract was not cytotoxic to normal cells. In contrast, the ethanolic extract of our study algae reduced the cell viability to 35% at 100µg/ml of concentration. This study demonstrated that the plant extract possesses significant cytotoxic potential, indicating its suitability as a natural source for developing novel cytotoxic agents against oral cancer.

Keywords: Apoptosis, cancer therapeutics and oral cancer, cytotoxicity, *Enteromorpha Compressa,* oral squamous cell carcinoma.

INTRODUCTION

Marine macroalgae, commonly known as seaweeds, are rich reservoirs of pharmacologically active metabolites and represent a promising source of alternative therapeutic agents. The bioactive constituents derived from these organisms are well acknowledged for their potent antioxidant activity and a broad spectrum of therapeutic effects. *Enteromorpha compressa* is a green macroalga belonging to the division Chlorophyta and is found on the marine coasts of India. It contains a rich array of phytoconstituents, including alkaloids, triterpenoids, steroids, flavonoids, lipids, and carbohydrates [1]. The anticancer activity of crude extracts from most seaweed species present in India has yet to be fully explored. Of particular interest is the activity of *E.compressa* against human oral squamous cell carcinoma (OSCC), which requires thorough investigation. Oral squamous cell carcinoma (OSCC) is an important issue in developing countries like India, where it is more prevalent. Its increasing incidence is because of a multifactorial etiology with determinants that are biological, behavioural and environmental. High consumption of tobacco, areca nut and betel quid significantly increases the risk, and immunosuppressive illnesses can increase susceptibility to oncogenic viral infections. Genetic susceptibility and malnutrition also increase the risk of developing the disease[2]. Despite major progress in diagnostic techniques and therapeutic advancements, cancer continues to be the second most common cause of death globally, as reported by the World Health Organisation (WHO). To determine the cytotoxic and anticancer properties of various compounds, the MTT assay is one of the most frequently employed *in vitro* methods. The reagent 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide is capable of entering viable cells by traversing both the plasma and mitochondrial membranes, a process facilitated by its lipophilic nature and positive charge. Within metabolically active cells, this compound is enzymatically reduced to form purple formazan crystals, which act as a measurable marker of cell viability and metabolic activity. In addition to this colourimetric approach, other techniques—such as radioisotope incorporation assays for DNA synthesis, automated cell counting, and dye-based viability tests—are also employed to evaluate cytotoxic effects and cellular responses [3].

MATERIALS AND METHODS

An In Vitro study was conducted using the Oral cancer cell line (KB cell line) and the Vero cell line. Both cell lines were procured from the National Centre for Cell Science (NCCS), Pune. The leaves *of E. compressa* were utilised in the study, and the crude ethanolic extract was evaluated for its cytotoxic potential. The Ethanol was used as a solvent due to its efficiency in dissolving a broad spectrum of compounds, compatibility with the cell lines used, ease of handling, and cost-effectiveness. Ethical approval was obtained from the institutional ethics committee (Letter No. SRMIEC-ST075-2731, dated 5th July 2025). Various procedures are as follows:

***Enteromorpha compressa* powder preparation**

Fresh green seaweed, *E.compressa*, was collected from the southern coastal region of India, and its identity was confirmed by a qualified botanist. The freshly gathered samples were thoroughly washed, initially by soaking them in tap water at three times their volume to eliminate surface salts and debris, followed by rinsing under running water to ensure complete removal of impurities. The cleaned seaweed was then shade-dried at room temperature for

about five to eight days, until the fronds became brittle and easily breakable by hand. Once dried, the material was pulverised into a fine powder using a low-speed electric blender to prevent heat degradation. The powdered sample was subsequently sterilised under ultraviolet (UV) light and stored in an airtight container for further experimental use.

Extract preparation

70g of Seaweed powder sample was dissolved in 250 mL of ethanol solvent and kept for 72 hours on a rotary shaker at 150 rpm at 25 °C temperature. The entire mixture was filtered and concentrated to dryness by evaporating on a vacuum evaporator, as the slightly modified procedure of [4].The extracted crude sample was kept in an airtight glass container and stored at 4 °C until further use (Table 1 and Figure 1).

MTT assay

The *in vitro* evaluation of the toxic effects of unknown compounds is often performed by determining the number of viable cells after staining with a vital dye. Among the various cytotoxicity assays available, the MTT assay is widely recognised for its simplicity, reliability, and reproducibility. The assay employs 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT), a water-soluble tetrazolium salt that forms a yellowish solution when dissolved in culture medium or salt solution devoid of phenol red. Within metabolically active cells, mitochondrial dehydrogenase enzymes cleave the tetrazolium ring of MTT, reducing it to insoluble purple formazan crystals. These crystals, being water-insoluble, are subsequently dissolved in solvents such as dimethyl sulfoxide (DMSO), acidified isopropanol, or ethanol, yielding a uniformly colored solution. The intensity of the purple color, measured spectrophotometrically, correlates directly with the number of viable cells. Thus, any increase or decrease in formazan formation reflects a corresponding change in cell viability, providing a quantitative measure of the cytotoxic potential of the test compound [5].

Preparation of test solutions

For the MTT assay, serial two-fold dilutions ranging from6.25 – 100 µg per ml were prepared and assessed for their cytotoxicity.

Cell lines and culture medium

The Vero and KB cell lines were procured from NCCS Pune. The stock cell was cultured in DMEM medium supplemented with 10% inactivated Fetal Bovine Serum (FBS), penicillin (100 IU/mL), and streptomycin (100 µg/mL) in a humidified atmosphere of 5% CO_2 at 37 °C until it became confluent.

PROCEDURE

The monolayer cell culture was trypsinised, and the resulting cell suspension was adjusted to a concentration of 1.0×10^5 cells/mL using the respective growth medium supplemented with 10% fetal bovine serum (FBS). A volume of 100 µL of this cell suspension, corresponding to 1×10^4 cells per well, was seeded into each well of a 96-well microtiter plate. After an incubation period of 24 hours, allowing the formation of a partial monolayer, the medium was carefully removed, and the wells were gently rinsed with fresh medium to eliminate unattached cells. Subsequently, 100 µL of the test sample at various concentrations was added to each well containing the adherent cells. The plate was then incubated at 37 °C in a 5% CO_2 humidified atmosphere for another 24 hours. Following incubation, the test solutions were discarded, and 20 µL of MTT reagent (2 mg/mL prepared in phosphate-buffered saline) was added to each well. The plate was further incubated for 4 hours under identical conditions to facilitate formazan crystal formation. Afterwards, the supernatant was carefully removed, and 100 µL of dimethyl sulfoxide (DMSO) was added to each well to dissolve the purple formazan product. The plate was then gently agitated to ensure complete solubilization. The optical density (OD) was measured at a wavelength of 570 nm using a microplate reader. The percentage of viable cells was calculated using the formula: viability = Sample abs/Control abs x 100.

RESULTS

At the end of 24 hrs IC_{50} value was calculated for the *E. compressa* ethanolic extract against the Vero cell line. The cells viable at varying concentrations of our extract was analysed. It was noted that even at the highest concentration of100µg/ml, more than65 %of cells were viable, thus the IC_{50} concentration was >100. (Figure 2 and Figure 3). At the end of 24 hrs IC_{50} value was calculated for the *E.compressa* Ethanolic extract against the Vero cell line. The cells viable at varying concentrations of our extract were analysed. It was noted that even at 50µg/ml, only 50% of the cells were viable, and at 100µg/ml, the cell viability was reduced to 35% when treated with the ethanolic extract of *E.Compressa* (Figure 4 and Table 2, Figure5).

DISCUSSION

Marine macroalgae are a rich source of bioactive molecules, and extracts prepared using alcohol and water have been shown to trigger cell death through mitochondria-regulated, caspase-dependent mechanisms. Nevertheless, research focusing on seaweeds from Indian waters is limited, and the specific anticancer activity of *E. compressa* against oral squamous cell carcinoma (OSCC) has not been thoroughly examined [6, 7]. Oral cancer has shown only a modest increase in survival rates over the past few decades despite significant changes in management and treatment options for these tumours. According to the latest data available, oral cancer has a 45% five-year survival rate. This trend calls for dynamic approaches to address the cause of the cancer, including traditional methods using plant-based medicines. OSCC remains a serious health concern due to its high incidence, late presentation, and considerable impact on patient survival and quality of life. Early detection through screening and awareness, combined with advances in molecular diagnostics and targeted therapies, holds the key to better management of this malignancy. Continued research is essential to improve therapeutic outcomes and reduce the global burden of OSCC [8, 9]. Extraction from plant based from plants plays a crucial role in the treatment of various diseases. There is substantial evidence to prove that herbal medicines are safer in many chronic conditions, like psoriasis. The extensive survey revealed that our algae, *E.compressa*, is an important alga with significant medicinal value. It also has a diverse pharmacological and phytochemical spectrum. The extract of algae showed the presence of many phytochemical constituents such as flavonoids, alkaloids and terpenoids. These phytochemicals elucidate various properties like antioxidant anti antimicrobial, and antiviral actions [11, 12].The antioxidant potential of *E.compressa* has been shown through various tests, including total antioxidant capacity and DPPH radical scavenging assays. In comparative studies, the ethyl acetate extract demonstrated stronger antioxidant activity than the ethanolic extract. This suggests the presence of effective compounds that neutralize free radicals. Furthermore, extracts of *E. compressa* were found to influence immune responses by reducing plasma cell activity, which lowers the secretion of IgE antibodies linked to food allergies. These immunomodulatory effects were confirmed in different mouse strains, regardless of their genetic background. Among the various solvents used for plant extraction, ethanol is often preferred due to its wide solubility range and compatibility with mammalian cell lines. Assays based on these cell lines are commonly used to explore the anticancer potential of natural extracts, offering a reliable in vitro model to assess their biological effectiveness [13]. The anti-cancer activities are mainly achieved by down regulation or upregulation of various carcinogenic pathways, like apoptosis and autophagy. The cytotoxicity of the extract should be evaluated in normal cell lines before it is tested for anticancer properties to ensure that it is safe to normal cells. In the present study, more than 65% of cells were viable even at the highest concentration of 100mg/ml, which proved that our extract was not cytotoxic to normal cells. *E.compressa* was also previously studied for its anticancer properties using FaDu cell lines and Cal33 cell lines. These cell lines are from the pharynx and tongue. The study concluded that the Methanolic extract of *E.compressa* showed anticancer properties by inducing apoptosis and autophagy. Our study also showed that the ethanolic extract had anticancer properties against the KB cell line. The cell viability was reduced to nearly 30%at 100mg/ml.

CONCLUSION

The results of this investigation demonstrated that *E.compressa* extract exhibited remarkable cytotoxic activity, indicating its potential as a natural lead for the development of new cytotoxic agents against oral cancer. Although these promising findings are encouraging, it is essential to conduct additional, rigorous, and detailed experimental studies, as well as well-designed clinical trials, to isolate, identify, and completely characterise the individual bioactive compounds responsible for their activity.

ABSTRACT

Pharmaceutical analysis is fundamental to ensuring the safety, efficacy, and quality assurance of drug products. With rapid advancements in pharmaceutical research and development (R&D), there has been a growing need for advanced analytical technologies capable of addressing the complexities of modern drug formulations. This review highlights key analytical methodologies used in contemporary pharmaceutical analysis and their critical role in drug characterization and quality control.Advanced analytical tools such as High-Performance Liquid Chromatography (HPLC), Gas Chromatography (GC), and Mass Spectrometry (MS) serve as essential techniques for the quantification, identification, and profiling of active pharmaceutical ingredients (APIs), excipients, impurities, and degradation products. The integration of these high-precision methods within pharmaceutical workflows has significantly improved analytical accuracy, method efficiency, and regulatory compliance. Collectively, these advancements have transformed the analytical landscape, ensuring robust drug development, process validation, and pharmaceutical quality management.

Keywords: HPLC, GC, LC–MS, Quality Control,Active Pharmaceutical Ingredients (APIs), Impurity Profiling, Regulatory Compliance.

INTRODUCTION

Pharmaceutical research has long been a cornerstone of medical progress, integrating knowledge from multiple scientific disciplines to develop effective therapeutic agents. Historically, drug discovery was primarily driven by chemistry and pharmacology, where new drugs often emerged from the creative synthesis and empirical testing of chemical compounds . However, with the advancement of biological sciences, molecular biology, genomics, and bioinformatics, the landscape of pharmaceutical innovation has transformed into a highly collaborative and multidisciplinary effort involving chemists, biologists, pharmacologists, and clinicians [1]. The modern drug development process begins with the identification and design of molecules exhibiting potential therapeutic activity—commonly referred to as active pharmaceutical ingredients (APIs) . These molecules are designed, synthesized, and characterized through a combination of computational modeling, high-throughput screening (HTS), and structure–activity relationship (SAR) studies . Following their discovery, APIs undergo rigorous analytical characterization to evaluate their purity, safety, pharmacokinetics, and pharmacodynamics, generating essential data to assess their therapeutic efficacy and safety for further development [2].

At the early stages of drug discovery, emphasis is placed on understanding the molecular and genetic basis of diseases. This includes identifying genetic mutations, altered signaling pathways, and protein–protein interactions that contribute to disease pathogenesis . Insights gained from these studies enable researchers to design or select molecules that modulate these targets with high specificity, leading to the discovery of potential lead compounds [3]. The integration of genomics, proteomics, metabolomics, and computational biology has significantly advanced target identification and validation, facilitating the transition from empirical drug discovery to rational drug design . Moreover, the continuous collaboration between chemists and biologists ensures that candidate molecules are not only potent but also safe, stable, and bioavailable, meeting the stringent requirements of pharmaceutical development [4].

Spectrophotometric Methods

Spectrophotometric methods, based on the principles of light absorption and transmission, have long been essential tools in pharmaceutical analysis and are well-documented in major pharmacopoeias (British, United States, and European). These techniques involve the quantitative measurement of light intensity absorbed or transmitted by a substance as a function of wavelength, providing valuable information about the analyte's concentration and purity [5]. Among these, UV–Visible spectrophotometry has gained prominence due to its simplicity, speed, cost-effectiveness, and high precision, making it ideal for routine analysis of pharmaceutical dosage forms . Colorimetric methods, a subset of spectrophotometric techniques, typically involve complex formation, oxidation–reduction reactions, or catalytic mechanisms, and are widely used in the assay of bulk materials and formulated products [6].
Another important approach, derivative spectroscopy, employs the first or higher-order derivatives of absorbance with respect to wavelength to enhance spectral resolution and resolve overlapping peaks . Although the concept was first explored in the 1950s, the development of microcomputers in the late 1970s enabled widespread application through precise mathematical derivatization. Derivative spectroscopy has since found applications not only in UV spectrophotometry, but also in infrared (IR), atomic absorption, and fluorescence spectrometry. However, as differentiation can reduce the signal-to-noise ratio, smoothing techniques are often applied to maintain spectral quality [7].

Overall, spectrophotometric methods, including colorimetry and derivative spectroscopy, continue to serve as reliable, efficient, and precise tools for the quantitative and qualitative determination of active pharmaceutical ingredients (APIs) in various formulations .

Near-Infrared Spectroscopy (NIRS)

Near-Infrared Spectroscopy (NIRS) is a rapid, non-destructive analytical technique capable of providing multi-component analysis of diverse substances without extensive sample preparation . In recent years, NIRS has gained

substantial attention in the pharmaceutical industry for its applications in raw material identification, quality assurance, and real-time process monitoring . Its advantages—such as minimal sample pre-treatment, fiber-optic compatibility, and the ability to simultaneously obtain chemical and physical information—make it superior to many conventional analytical techniques [8]. NIRS has also been formally recognized by major pharmacopoeias, including the European Pharmacopoeia (Ph. Eur.) and the United States Pharmacopoeia (USP), which provide guidance on its validation and suitability for pharmaceutical testing . When integrated with multivariate data analysis techniques (e.g., Principal Component Analysis or Partial Least Squares Regression), NIRS becomes a powerful tool for both qualitative identification and quantitative determination of pharmaceutical components . Hence, the combination of Near-Infrared Spectroscopy and chemometric modeling represents a pivotal development in modern pharmaceutical analysis, offering real-time, reliable, and environmentally friendly analytical solutions [9].

Chromatographic Techniques

Chromatography remains one of the most powerful and versatile tools in pharmaceutical analysis, enabling the separation, identification, and quantification of active pharmaceutical ingredients (APIs), impurities, and degradation products. Various chromatographic methods, including Thin Layer Chromatography (TLC), High-Performance Thin-Layer Chromatography (HPTLC), and High-Performance Liquid Chromatography (HPLC)—as well as hyphenated techniques like Liquid Chromatography–Mass Spectrometry (LC–MS)—play crucial roles in ensuring drug quality and purity [10].

Thin Layer Chromatography (TLC)

Although regarded as one of the earliest chromatographic techniques, Thin Layer Chromatography (TLC) continues to be widely employed in pharmaceutical quality control and research laboratories due to its simplicity, cost-effectiveness, and versatility . In TLC, a solid adsorbent layer—typically silica gel, alumina, or cellulose—is coated on a solid support such as glass, plastic, or aluminum plates, and the sample components are separated based on differential adsorption and solubility in the mobile phase . The effectiveness of TLC depends on several factors, including the selectivity of the adsorbent, composition of the mobile phase, and sample properties. TLC offers key advantages such as minimal sample preparation, high sample loading capacity, and flexibility in choosing solvents . In pharmaceutical analysis, it is particularly useful for screening unknown substances, assessing purity, and monitoring reaction progress during drug synthesis.

Furthermore, TLC can be adapted for quantitative analysis by eluting separated spots and performing spectrophotometric measurement of the analytes. The technique has been effectively utilized in the determination of compounds such as steroids, pioglitazone, and noscapine, demonstrating its analytical relevance in modern pharmaceutical practices . In early stages of drug development, where limited information exists about impurities or degradation products, TLC serves as an indispensable preliminary screening tool [11].

High-Performance Thin-Layer Chromatography (HPTLC)

Advancements in chromatographic science have led to the evolution of High-Performance Thin-Layer Chromatography (HPTLC)—an enhanced form of conventional TLC characterized by finer particle size stationary phases, automated sample application, and densitometric scanning . HPTLC provides rapid, high-resolution separations and allows for the analysis of complex or crude samples with greater accuracy and reproducibility [12].
Its major advantages include shorter analysis times, high throughput, and the capability for multi-sample analysis on a single plate. These features make HPTLC particularly valuable in herbal drug standardization, stability testing, and bioactive compound profiling . Owing to its simplicity and robustness, HPTLC remains a reliable and cost-effective alternative to high-end chromatographic systems for routine pharmaceutical applications .

High-Performance Liquid Chromatography (HPLC)

High-Performance Liquid Chromatography (HPLC) has become the most widely used chromatographic technique in pharmaceutical analysis, owing to its exceptional specificity, precision, and reproducibility . Introduced in the late

1970s and incorporated into the United States Pharmacopoeia (USP) and European Pharmacopoeia (Ph. Eur.) by the 1980s, HPLC is now a standard method for assaying bulk drug substances, formulations, and stability samples [13].
HPLC operates by forcing a liquid mobile phase through a column packed with a stationary phase, where sample components are separated based on their differential interactions with the two phases. Among its detection systems, UV detectors and photodiode array (PDA) detectors are most commonly used. PDA detectors offer multi-wavelength monitoring, spectral analysis, and peak purity evaluation, making them highly valuable in method development and impurity profiling . Other detectors, such as refractive index (RI), electrochemical, and fluorescence detectors, further extend HPLC's applicability. For example, fluorescence detection offers high sensitivity for trace-level analysis of drugs and metabolites, while refractive index detection is useful for non-UV absorbing compounds . The reversed-phase HPLC (RP-HPLC) mode, utilizing nonpolar stationary phases like C18, is the most prevalent form due to its speed, robustness, and sensitivity. It has been successfully applied for the analysis of a wide variety of pharmaceuticals in formulations, biological fluids, and stability studies . Despite its advantages, HPLC has limitations such as high operational costs, solvent consumption, and limited column reproducibility over extended use [14].

Liquid Chromatography–Mass Spectrometry (LC–MS)

To overcome the limitations of traditional detectors, hyphenated techniques such as Liquid Chromatography–Mass Spectrometry (LC–MS) have emerged as powerful tools in modern pharmaceutical analysis [15]. LC–MS combines the separation efficiency of HPLC with the molecular identification capability of mass spectrometry, making it invaluable for drug assay, impurity profiling, and metabolite identification . LC–MS is now a preferred technique in quality control, pharmacokinetic studies, and stability testing, enabling accurate detection of trace impurities and degradation products. Its ability to provide molecular weight, structural information, and quantitative data from a single analysis has revolutionized pharmaceutical characterization. However, LC–MS systems are expensive and require skilled operation, and their maintenance can be resource-intensive . Nonetheless, LC–MS represents a cornerstone of modern analytical science, offering unmatched sensitivity, selectivity, and versatility for ensuring drug safety, efficacy, and quality .

Gas Chromatography (GC)

Gas Chromatography (GC) is a highly efficient analytical technique used for the separation, identification, and quantification of volatile and semi-volatile organic compounds. It provides exceptional resolution, sensitivity, and reproducibility, making it indispensable for analyzing complex mixtures, even at trace-level concentrations [16].
In the pharmaceutical field, Gas–Liquid Chromatography (GLC) plays a crucial role, particularly for the analysis of volatile impurities, residual solvents, and drug degradation products . However, GC has inherent limitations when applied to compounds with high molecular weight or thermal instability, as many pharmaceutical compounds lack sufficient volatility. To address this, derivatization techniques are often employed to enhance volatility and thermal stability before analysis. GC has been successfully utilized in the quantitative determination of drugs such as isotretinoin and cocaine, as well as in assessing residual solvents in pharmaceutical formulations like betamethasone valerate. Furthermore, it is extensively applied for impurity profiling, particularly process-related impurities that may arise during synthesis or formulation .

In pharmaceutical quality control, GC coupled with sensitive detectors, including the Flame Ionization Detector (FID), Electron Capture Detector (ECD), and Mass Spectrometry (GC–MS), offers powerful means for residual solvent analysis, which is regulated under International Conference on Harmonisation (ICH) guidelines Q3C . These capabilities make GC a vital tool in ensuring compliance with global regulatory standards for drug safety and purity.
In summary, GC remains an essential analytical technique in pharmaceutical analysis due to its accuracy, selectivity, and reproducibility in quantifying volatile components, impurities, and solvents in complex drug formulations [17].

Nuclear Magnetic Resonance Spectroscopy (NMR)

Nuclear Magnetic Resonance (NMR) spectroscopy is a non-destructive and highly informative analytical technique that provides detailed insights into the molecular structure, dynamics, and composition of chemical compounds.

Since the pioneering work of Shuker et al. (1996), which demonstrated NMR's potential in drug molecule screening, the technique has become an indispensable tool in both academic and industrial pharmaceutical research . Recent advancements in high-field NMR instrumentation and multidimensional NMR techniques have significantly expanded its analytical capabilities, allowing for precise molecular characterization, impurity profiling, and quantitative analysis of pharmaceutical compounds [9]. In addition to structure elucidation, NMR is increasingly employed for quantitative NMR (qNMR) applications, enabling direct and absolute quantification of active ingredients and impurities without the need for reference standards . NMR has proven particularly useful in the characterization of complex drug formulations, identification of degradation products, and metabolomic studies aimed at understanding drug metabolism and pharmacokinetics. It also supports regulatory submissions by providing confirmatory evidence for drug identity, purity, and stability . Numerous reviews and studies have highlighted NMR's critical role in modern pharmaceutical sciences, especially when integrated with complementary techniques like mass spectrometry (MS) and chromatography to form hyphenated systems (e.g., LC–NMR, LC–NMR–MS) that enhance analytical performance . In conclusion, NMR spectroscopy stands as a powerful, precise, and versatile tool in contemporary pharmaceutical analysis, contributing significantly to drug development, quality control, and structural elucidation [18].

Kinetic Methods of Analysis

Kinetic methods of analysis have been an integral part of analytical chemistry since their emergence in the 1950s, and they continue to gain renewed interest due to significant advancements in instrumentation, automation, data analysis, and mechanistic understanding of chemical reactions . These methods are based on monitoring the rate of change in concentration of an analyte or reaction product over time, rather than measuring equilibrium states as in conventional methods . In kinetic analysis, the analyte typically participates in a time-dependent chemical reaction, and changes in absorbance, fluorescence, or other measurable signals are tracked to determine its concentration. The technique is particularly advantageous when rapid, selective, and automated determinations are required .

Common kinetic approaches include the fixed-time method and the initial-rate method, both of which have been widely used in pharmaceutical analysis to quantify drugs in dosage forms . Automated kinetic techniques—such as the stopped-flow method and the Continuous Addition of Reagent (CAR) system—offer precise control of reaction conditions and allow for high-throughput measurements. The CAR technique, in particular, has been applied to the determination of pharmaceutical compounds using photometric and fluorimetric detection . Catalysts and micellar media are often incorporated into kinetic systems to accelerate reactions, improve sensitivity, and enhance selectivity. Micellar catalysis, for instance, increases reaction rates by providing a unique microenvironment that facilitates reagent–analyte interactions . Moreover, multicomponent kinetic approaches, such as the differential rate method, have proven effective in resolving overlapping spectral data in multi-drug formulations . Two advanced techniques, the kinetic wavelength pair method and the H-point standard addition method, have also been developed to address spectral overlap in binary mixtures, enhancing accuracy and selectivity in pharmaceutical assays . In summary, kinetic methods provide robust, selective, and rapid analytical alternatives to equilibrium-based assays, offering significant promise in drug quantification, reaction mechanism studies, and formulation quality control [19].

Electrophoretic Methods

Capillary Electrophoresis (CE) has emerged as a powerful and versatile analytical tool in pharmaceutical analysis. It operates by separating charged species within a narrow capillary under the influence of a high-voltage electric field, enabling high-resolution separation and detection of analytes in complex matrices . During analysis, solutes migrate at different rates depending on their charge-to-size ratio, and the detector signal—usually UV or fluorescence-based—produces peaks whose areas are proportional to analyte concentrations, facilitating quantitative analysis . Capillary electrophoresis is advantageous due to its high separation efficiency, minimal sample and reagent requirements (nanolitre-scale injection volumes), and rapid analysis times. Furthermore, CE can be performed under aqueous or physiological conditions, making it suitable for biopolymers, peptides, proteins, and pharmaceutical compounds .

Various CE modes have been developed to meet diverse analytical needs:

- Capillary Zone Electrophoresis (CZE) for simple ionic separations.
- Micellar Electrokinetic Chromatography (MEKC) for neutral and hydrophobic analytes.
- Isotachophoresis (ITP) for sample preconcentration and ionic analysis.
- Capillary Gel Electrophoresis (CGE) for large biomolecules like proteins and nucleic acids.
- Isoelectric Focusing (IEF) for protein characterization based on isoelectric points.
- Affinity Capillary Electrophoresis (ACE) for studying molecular interactions and binding affinities.

CE has been successfully applied to drug purity testing, impurity profiling, enantiomeric separation, and pharmacokinetic studies, making it a valuable alternative to chromatographic techniques in pharmaceutical laboratories . In conclusion, capillary electrophoresis offers a combination of speed, efficiency, minimal solvent use, and versatility, establishing itself as a vital tool for routine pharmaceutical quality control and bioanalytical studies [20].

Flow Injection and Sequential Injection Analysis

The development of laboratory automation in the latter half of the 20th century revolutionized analytical chemistry. Among the most influential innovations was Flow Injection Analysis (FIA), introduced by Ruzicka and Hansen in Denmark and Stewart in the United States, which established the foundation for modern automated analytical systems . This technique represented a paradigm shift in analytical practice by allowing rapid and reproducible instrumental measurements without the need to reach chemical or physical equilibrium [21]. Flow Injection Analysis (FIA) operates on the principle of injecting a discrete sample volume into a continuous, unsegmented flow of a carrier liquid. As the sample travels through the flow path, it forms a well-defined dispersion zone, within which it undergoes controlled mixing and reaction before reaching the detector. The detector continuously monitors changes in measurable parameters—such as absorbance, fluorescence, conductivity, or electrode potential—produced as the sample passes through the flow cell, allowing real-time signal acquisition [22].

The key advantages of FIA include high sample throughput, minimal reagent consumption, reproducibility, and automation compatibility . These characteristics make it particularly suitable for pharmaceutical quality control, where rapid and accurate determinations of active pharmaceutical ingredients (APIs), excipients, and impurities are essential . FIA has been effectively applied to a wide range of matrices, including solid dosage forms, creams, ointments, suspensions, emulsions, and solutions, offering versatility in pharmaceutical analysis . In addition to conventional FIA, the Sequential Injection Analysis (SIA) technique, developed as a second-generation automation system, offers greater flexibility and precision through the programmable control of flow direction and timing. SIA minimizes reagent waste and allows multiple assays to be performed using the same manifold setup . Both FIA and SIA have found extensive applications in routine drug assays, dissolution testing, and stability studies, supporting the demand for cost-effective, environmentally friendly, and automated analytical approaches in modern pharmaceutical laboratories . In summary, flow injection and sequential injection analysis represent major advancements in the automation of pharmaceutical analysis, offering rapid analysis, low reagent consumption, and high reproducibility, thereby enhancing the efficiency and reliability of pharmaceutical quality assessment [23].

CONCLUSION

In conclusion, advanced analytical techniques have become a cornerstone of modern pharmaceutical analysis, profoundly transforming drug development and quality control. The integration of sophisticated methods such as Liquid Chromatography–Mass Spectrometry (LC–MS), Nuclear Magnetic Resonance (NMR) spectroscopy, and other cutting-edge tools has greatly enhanced our ability to characterize and understand pharmaceutical compounds. These analytical approaches offer invaluable insights into chemical composition, structural elucidation, impurity profiling, and solid-state characterization, all of which are essential for informed decision-making in drug formulation and process optimization.

By enabling the accurate detection and quantification of impurities, ensuring batch-to-batch consistency, and improving drug safety and efficacy, these methods uphold the highest standards of pharmaceutical quality. As the field continues to evolve, it is crucial for researchers and industry professionals to stay abreast of technological innovations and adopt these advanced analytical methodologies. Doing so will pave the way for the development of safer, more effective, and more sustainable pharmaceutical products, marking a new era in pharmaceutical science and innovation.

ABSTRACT

The textile sector provides enormous quantity accumulation of post consumption and post-industrial waste. The minimal waste utilized for several purposes, huge post-consumer wastes are dumped into the land causing pollution and landfills. The review analyses the method, properties and further investigations of each method of fabric shredding ranging from mechanical, thermos mechanical, Enzymatic and chemical. From different articles and studies different methods of recycling is evaluated. Mechanical recycling, the most established method, is a cost-effective, scalable solutions through shredding and melt-processing, diverting 60–70% of textile waste from landfills. However, its limitations in handling blended fabrics and fibre quality degradation (up to 30–50% strength loss) underscore the need for complementary technologies. Emerging enzymatic processes address these gaps, achieving selective degradation of natural fibres. while preserving synthetic integrity. Ionic liquids (ILs) demonstrate precision in cellulose regeneration from blended waste, though high costs and solvent toxicity hinder industrial adoption. Thermochemical methods**,** including pyrolysis (800–900°C) and steam activation, convert non-recyclable synthetics like acrylic into high-value activated carbons or biofuels. After thorough review it is concluded that mechanical recycling's dominance in bulk processing, while enzymatic and IL-based methods excel in blended textile separation. Thermochemical pathways valorise otherwise land filled materials but face energy-intensity challenges. Hybrid systems integrating mechanical preprocessing with enzymatic/ionic refinement show potential, improving material recovery rates by 20–30%. The review advocates for circular economy frameworks combining extended producer responsibility R and D investments in enzyme engineering and IL recovery, and AI-driven sorting to enhance feedstock purity. By synergizing mechanical recycling's practicality with emerging methods precision, the textile sector can achieve 45–60% waste diversion, reducing reliance on virgin resources and cutting sectoral CO_2 emissions.

Keywords: Mechanical Recycling, Enzymatic Separation, Il-Ionic Liquids, Thermochemical Conversion, Blended Textiles, Circular Economy, Hybrid Systems.

INTRODUCTION

Throughout human civilization, textiles have served as essential materials addressing multifaceted socio-cultural, religious, political, and economic requirements. This persistent reliance has resulted in a continuous accumulation of textile waste, driving the need for innovative recycling solutions that prolong material usefulness beyond their original applications. The core principle of recycling - converting end-of-life products into valuable new materials has become a vital approach for environmental preservation within the textile industry.[1] The global textile industry faces an unprecedented waste crisis, with over 92 million tons of discarded fabrics annually exacerbating environmental degradation and resource depletion. Fast fashion's rapid production cycles and the proliferation of blended synthetic-natural textiles (e.g., polyester-cotton) have created complex waste streams that conventional recycling methods struggle to process [2]**.** The fast fashion model, characterized by abbreviated product lifespans and large-scale manufacturing, has generated extraordinary quantities of discarded textiles, much of which is disposed of in landfills before reaching its full potential lifespan. This linear consumption framework presents serious environmental risks, creating an imperative need to shift toward circular economy practices in textile manufacturing and waste processing [3]**.** India's situation offers both distinctive possibilities and difficulties in textile waste management. Long-standing traditions of textile reuse in crafts and domestic applications reveal historical foundations of circular principles. However, contemporary recycling systems remain insufficiently developed, facing challenges with mixed-material fabrics and inefficient collection mechanisms [4]. Textile waste recycling represents a fundamental component of this necessary transition, providing simultaneous advantages of resource reclamation and ecological safeguarding. Present recycling techniques can be generally divided into mechanical and chemical processes. Mechanical methods, such as melt extrusion and fibre recovery, are utilized in building materials and industrial textile applications. Chemical approaches including depolymerization and solvent-assisted fiber breakdown allow for molecular-level recycling, especially effective for synthetic fabrics [4]. The critical parameters determining recycling performance are summarized and discussed and focus on the current challenges in mechanical and chemical recycling (pyrolysis, enzymatic hydrolysis, hydrothermal, ammonolysis, and glycolysis). Textile waste has been demonstrated to be re-spun into yarn (re-woven or knitted) by spinning carded yarn and mixed shoddy through mechanical recycling [5]**.** Textile waste has also become a greater threat to modern society mainly because of constant growth in the production and consumption of non-biodegradable synthetic fibres. Unless adequately treated, textile wastes from hospitals may carry hazardous pathogens whilst many fashion clothing items contain non-bio-degradable chemicals which can create havoc in the environment following their disposal, so the recycling of waste textiles has grown in importance. Many studies have shown that much of what would otherwise become waste textiles could be successfully upcycled to produce value-added products [6]. This systematic mini-review critically evaluates both established and innovative textile recycling methodologies, analysing their technical feasibility, environmental impact, and potential for integration into circular frameworks.

Objectives

- To analyse the textiles waste and Recycling methods
- To study the different types of Fabric Shredding Techniques
- To analyse the suitable method in fabric recycling for further Research
- To investigate the materials used different methods

Textile Waste and Environmental Impact

Textile waste from the fashion industry can be classified into industrial, pre-consumer, and post-consumer waste. Industrial waste, generated during fiber, yarn, fabric, and garment production, includes substandard fibres, trimmings, cutoffs, and defective materials. Unlike other waste types, industrial waste often has known fiber composition, chemical treatments, dyes, and finishes, enhancing its recyclability. This characteristic makes it a more viable candidate for recycling compared to other textile waste categories. [7]. Textile waste in the fashion industry is categorized into industrial, pre-consumer, and post-consumer waste. *Industrial waste* arises during manufacturing and includes substandard fibres, trimmings, and defective materials, often with known composition, facilitating

recycling. *Pre-consumer waste* consists of unsold stock and returns, which some experts classify as industrial waste due to the industry's disposal responsibility. *Post-consumer waste* comprises discarded garments and household textiles, typically disposed of in domestic waste or donated. Since these used textiles are not deemed hazardous, their collection is primarily managed by private firms and charities rather than municipal systems [7]. waste from ring-spinning processes in cotton shirting production can be repurposed into fabrics for shirts, jackets, and trousers [9]. However, most textile waste is either landfilled or incinerated, posing environmental and economic challenges. To mitigate these impacts, sustainable waste management strategies—such as reprocessing waste into value-added products—must be adopted to reduce ecological harm and promote circularity in the textile industry [8]. The fashion and textile industries are major contributors to global CO2 emissions, underscoring the critical need to shift from a linear "take-make-waste" model to a circular economy. However, this transition presents complex challenges, particularly due to the overwhelming volume of annual textile waste, which exceeds industry forecasts. While recycling technologies have advanced, significant obstacles remain in the collection and sorting of textile waste, exacerbated by fragmented waste management systems that impede effective post-consumer waste handling. To overcome these barriers, intensified efforts in waste collection, sorting, and pre-processing are essential, alongside regulatory measures to incentivize circular business models and improve waste recovery.

Initiatives such as the Sustainable and Circular Textiles Strategy demonstrate progress in reducing dependence on virgin resources and promoting sustainable textile recycling. Nevertheless, achieving a fully circular textile market in the near term will require coordinated collaboration and innovative approaches. Despite persistent challenges in scalability and technological constraints, recent advancements in textile recycling—including bio-based chemical processes and thermochemical recycling—offer promising alternatives to virgin fibers. These developments signal a growing potential for scalable, sustainable solutions, marking a pivotal step toward a more circular and environmentally responsible textile industry [10]. The study by Öndoğan *et al*. (2022) critically examines the environmental and socio-economic repercussions of the fashion industry, highlighting its paradoxical role as both a major economic driver and a significant polluter. Despite contributing $3 trillion annually—accounting for 2% of global GDP—the sector generates alarming environmental degradation, including 60 billion m² of textile waste in 2015 alone and 20% of global wastewater. The authors underscore the industry's high carbon footprint, responsible for 10% of global greenhouse gas emissions, exacerbated by energy-intensive production and extensive supply chains. Furthermore, the study emphasizes the sector's detrimental ecological impacts, such as water pollution from toxic chemical discharges, which threaten aquatic ecosystems, alongside workplace hazards like emissions and volatile organic compounds. The industry's efforts toward digitization and innovation to maintain competitiveness, and at true sustainability requires a holistic approach, integrating ecological, economic, and social dimensions. Their analysis aligns with broader scholarly discourse calling for systemic reforms, including circular economy models and stricter regulatory frameworks, to mitigate the industry's environmental and ethical liabilities while preserving its economic vitality. This study serves as a valuable contribution to understanding the complex interplay between profitability and sustainability in global fashion markets [11].

Sustainable Innovations in Textile Recycling for a Circular Economy

Current textile recycling methods play a pivotal role in sustainable waste management, offering diverse approaches to mitigate environmental impacts while conserving resources. The recycling landscape can be categorized into four principal methods: upcycling, downcycling, closed-loop, and open-loop recycling, each serving distinct purposes in waste diversion[12,13,14]. Upcycling transforms materials into higher-value products, while downcycling produces lower-quality outputs. Closed-loop recycling maintains materials within the same product cycle, exemplified by fiber-to-fiber recycling, whereas open-loop recycling repurposes materials for entirely different applications, often resulting in downcycled products [15]. Open-loop processes, such as converting plastic bottles into polyester textiles, currently dominate recycled textile production due to their practicality and existing infrastructure. While closed-loop systems offer superior environmental benefits by preserving material integrity, open-loop recycling provides immediate solutions for waste reduction and decreased reliance on virgin materials.[12,13,16] Both approaches significantly reduce greenhouse gas emissions by minimizing the energy-intensive production of new materials, demonstrating their collective importance in sustainable textile management.Sustainable nonwoven leather-like

materials can be produced through microbial and fungal upcycling of agricultural waste. These biofabricated alternatives exhibit visual, textural, and mechanical properties comparable to conventional leather while being synthesized via simple, scalable, and cost-efficient processes. Such eco-friendly substrates hold significant potential for applications in the textile and footwear industries as viable leather substitutes[17]. Telli (2014) addressed the growing demand for innovative applications of fine yarn waste by exploring its potential use in the hair interlining industry. The study examined key challenges in hair interlining production and proposed an eco-conscious solution through yarn waste upcycling. By identifying optimal waste utilization methods, the research demonstrated that singeing and sizing steps could be eliminated, thereby streamlining production. Notably, the resulting environmentally sustainable hair interlinings exhibited reduced shrinkage compared to conventional materials. This work presents both technical and ecological advancements, offering a novel approach to waste valorization while enhancing manufacturing efficiency in the textile industry [18]. Kotula *et al*. identified significant quantities of human hair waste in municipal solid waste (8.6 million tons) and fashion industry waste streams (2.5 million tons). Given its current classification as a low-value byproduct in most societies, the study advocates for the valorization of HH as a reinforcement material in polymer composites. Such natural fiber-reinforced composites offer distinct environmental advantages, making them particularly suitable for sustainable applications in construction (e.g., wall partitioning) and transportation (e.g., automotive components) sectors **[**19].

Types of Recycling methods

Mechanical Recycling

Mechanical recycling stands as the most established and widely implemented textile recycling technology, operating through two primary mechanisms. The first involves conventional shredding and carding processes that transform textiles into shorter fibers, commonly referred to as "shoddy," which find application in non-woven products like insulation materials and industrial rags. Recent advancements in Garnett machine technology have improved fiber extraction efficiency, enabling the production of higher-quality outputs suitable for some wearable textiles. The second approach employs thermo-mechanical processing for thermoplastic materials like polyester and nylon, melting and reforming them into recycled fibres with better quality retention than mechanically shredded counterparts[20,21].

Chemical Recycling

Chemical recycling technologies have emerged as sophisticated solutions for synthetic textile waste, particularly for polyester and nylon materials. These processes employ various depolymerization techniques such as hydrolysis, glycolysis, and methanolysis to break down polymers into their constituent monomers or oligomers. The resulting materials can be repolymerized into high-quality resins, enabling near-virgin quality fiber production and true closed-loop recycling potential.[22,23]. Specific methods demonstrate material selectivity, with methanolysis proving particularly effective for nylon 6 conversion to caprolactam, while hydrolysis better serves nylon 6,6 recycling. For polyester, innovative chemical-mechanical hybrid processes have shown promise in separating blended fabrics, though pure feedstock recycling remains more economically viable. The technology also extends to man-made cellulosic fibers, representing a growing market segment[23,15,25]. However, chemical recycling faces substantial challenges, including high energy demands ranging from 6,599 to 7,479 kWh per ton of processed textiles, significant operational costs exceeding both mechanical recycling and virgin production, and environmental concerns regarding solvent use[21,26,27,25] These limitations currently restrict widespread industrial adoption, despite the technology's superior quality outputs and closed-loop potential.

Biochemical Recycling

Biochemical recycling methods present an environmentally promising alternative for cellulosic and synthetic textile waste processing, utilizing enzymatic catalysis to depolymerize materials. These processes typically begin with acidic or alkaline pretreatments to disrupt fiber structures, followed by targeted enzymatic hydrolysis. For cellulose-based materials, this approach efficiently breaks down both amorphous and crystalline regions, offering superior conversion rates compared to conventional chemical methods. The technology also shows potential for synthetic textiles, with enzymes capable of cleaving ester bonds in polyester, though surface-limited reactions currently hinder

economic viability. [21,26,27]. Significant challenges persist in biochemical recycling, particularly for synthetic polymers with carbon-carbon backbones that resist enzymatic degradation. While certain fungi and bacterial consortia have demonstrated limited capability in degrading polypropylene and polystyrene, the absence of efficient, commercially viable biocatalysts for most synthetic textiles remains a major barrier. Recent advances in thermophilic microbial consortia have shown improved degradation rates, suggesting potential future developments. However, the current limitations in enzyme accessibility, reaction rates, and scalability restrict widespread industrial application, positioning biochemical methods as a promising but not yet fully realized solution for comprehensive textile recycling. The comparative analysis of these recycling technologies reveals a complex landscape where no single method provides a universal solution. Mechanical processes offer immediate, scalable solutions with lower environmental impact but produce inferior quality materials. Chemical methods deliver high-quality outputs suitable for closed-loop systems but face economic and energy intensity barriers. Biochemical approaches present environmentally benign alternatives but require significant technological advancement for broad implementation.[21,26,27,25] This technological diversity underscores the need for integrated recycling systems that combine multiple approaches based on material type, desired output quality, and environmental considerations. The future of textile recycling lies in developing hybrid systems that optimize the strengths of each method while addressing their respective limitations, ultimately creating a comprehensive, sustainable solution for global textile waste management. Continued research and innovation across all technological fronts remain essential to achieve true circularity in the textile industry and meet growing sustainability demands.

Primary Textile Recycling: Methods and Considerations

Primary recycling, often referred to as "closed-loop" or "original recycling," represents one of the most sustainable approaches to textile waste management. This method focuses on reprocessing synthetic fibres—particularly polyethylene terephthalate (PET) and polyamide (PA)back into their original polymer form, maintaining near-virgin material quality. The process involves collecting, cleaning, and processing post-industrial or post-consumer textile scraps, which can then be reintroduced into production cycles, either as standalone recycled material or blended with virgin polymers to enhance performance characteristics. A key advantage of primary recycling lies in its economic and operational efficiency. Compared to mechanical or chemical recycling, it requires less energy and fewer processing steps, reducing overall costs while preserving polymer integrity. This makes it particularly valuable for high-value synthetic textiles where material properties must remain consistent, such as in technical or performance fabrics. However, the method faces significant limitations, primarily its restricted applicability to homogeneous, uncontaminated waste streams. Mixed-material textiles, heavily dyed fabrics, or composites containing non-recyclable additives cannot be processed through primary recycling, necessitating alternative methods such as chemical depolymerization or mechanical downcycling. Despite these constraints, primary recycling remains a critical component of sustainable textile production, particularly for industries prioritizing circularity in polyester and nylon products. Ongoing advancements in sorting and purification technologies may expand its applicability, though current infrastructure still favors large-scale, single-material waste streams. As such, while primary recycling offers an optimal solution for specific textile categories, its broader implementation depends on improved waste segregation systems and the development of complementary recycling technologies to handle more complex textile waste compositions [28,29].

Hierarchy of Textile Recycling Methods From Material Recovery to Energy Conversion

The textile recycling sector employs a multi-tiered approach to waste valorization, categorized into four distinct methodologies based on their output characteristics and processing techniques. Secondary recycling represents a transformative process where post-consumer textile waste is converted into new materials with altered physical or chemical properties compared to their original form[30,31]. This method encompasses comprehensive waste collection systems followed by mechanical or chemical reprocessing, with the final product quality heavily dependent on input waste composition, purity levels, and the sophistication of processing technologies [32,33]. Economic viability remains a critical consideration, as secondary recycling must balance processing costs against the market value of the resulting materials. Tertiary recycling, alternatively termed feedstock or chemical recycling, employs advanced decomposition techniques including pyrolysis, gasification, and hydrolysis to break down textile

polymers into their fundamental chemical constituents [33]. Particularly effective for synthetic textiles, this approach yields valuable outputs such as monomers for polymer re-synthesis or hydrocarbon fuels, though it demands rigorously sorted and cleaned waste streams to ensure process efficiency [32]. The method's strength lies in its ability to handle mixed or contaminated textiles that cannot be processed through mechanical means, though energy intensity and operational costs present ongoing challenges. Quaternary recycling occupies the final tier in the waste hierarchy, focusing on energy recovery through controlled incineration of non-recyclable textile waste [34]. While this approach provides thermal energy utilization, it represents the least preferred option in circular economy frameworks due to irreversible material loss and emissions concerns. The textile recycling paradigm thus demonstrates a clear technological progression: primary and secondary methods prioritize material conservation through mechanical reprocessing of industrial by-products, while tertiary and quaternary approaches address more complex waste streams through chemical conversion or energy recovery [33]. This hierarchy reflects both the current state of textile recycling technologies and the evolving priorities of sustainable material management in the fashion and textile industries.

Recycling Limitations

While textile recycling processes effectively delay material entry into natural ecosystems [34], growing research emphasizes the need to establish clear recyclability thresholds and optimize process parameters [34,35]. The heterogeneous nature of textile waste necessitates a diversified technological approach, as no single recycling method can effectively process all material types [35]. This reality has driven the development of complementary techniques, exemplified by chemical recycling's emergence to address the quality limitations inherent in mechanical processes [36]. Current textile recycling methodologies—spanning mechanical, chemical, thermal, and thermomechanical approaches—all present distinct material quality compromises. Mechanical methods degrade fiber length and strength, chemical processes face energy and cost barriers, while thermal treatments often alter material properties. Recognizing these constraints, researchers are exploring alternative valorisation pathways including:

- Biological treatments (anaerobic digestion, fermentation)
- Organic recycling (composting for biodegradable textiles)
- Composite material production for construction applications [36,37]

These alternatives demonstrate the textile industry's evolving approach to waste management, where traditional recycling methods are increasingly supplemented with innovative solutions tailored to specific material characteristics and environmental considerations. The field continues to progress toward a more nuanced waste hierarchy that balances circularity principles with practical material constraints [39].

Innovative Enzymatic Approach

This approach represents a significant advancement over conventional mechanical or chemical recycling methods for blended textiles, which often degrade material quality or require energy-intensive processes. By enabling clean separation of natural and synthetic fibres while preserving material properties, the technique offers a sustainable pathway for increasing recycling rates of complex textile waste streams. The dual-output system aligns with circular economy principles by creating multiple value streams from waste materials - high-quality polyester for fiber recycling and protein hydrolysates for agricultural or industrial applications. [39] The growing volume of textile waste, particularly from post-consumer sources, poses significant environmental challenges due to the prevalence of blended fabrics combining natural and synthetic fibres. Conventional recycling methods struggle with these complex multicomponent textiles, as effective fiber-to-fiber recycling typically requires separation into pure material streams. This study presents an innovative enzymatic approach to selectively degrade wool fibres from wool/polyester blends while preserving the synthetic component for high-quality recycling [40,40]. The research demonstrates successful wool fiber digestion using a two-step keratinase treatment supplemented with a reducing agent, achieving complete breakdown of the natural fibers while leaving polyester fibers intact. Advanced characterization techniques, including electron microscopy and spectroscopic analysis, confirmed that the enzymatic process does not compromise the structural or mechanical properties of the recovered polyester. The undamaged polyester fibers maintain quality comparable to virgin material, making them suitable for reprocessing into new yarns and textile products[40]. Beyond synthetic fiber recovery, the process generates valuable byproducts in the form of nutrient-rich

keratin hydrolysates. These protein derivatives show potential applications as microbial growth media, bio-fertilizers, or animal feed additives, contributing additional circular economy benefits. The enzymatic separation method addresses two critical challenges in textile recycling: the difficulty of processing blended fabrics and the need for value retention in both fiber components.[40] Future research directions should focus on scaling the enzymatic process, optimizing reaction conditions for different blend ratios, and investigating applications for the keratin byproducts. The method's environmental benefits could be further enhanced through life cycle assessment comparing it to conventional recycling approaches. This work provides a foundation for developing biological solutions to one of the most persistent challenges in textile recycling - the effective processing of mixed fiber waste streams [40]. The successful demonstration of this enzymatic separation technique suggests promising applications beyond wool/polyester blends, potentially adaptable to other natural/synthetic combinations. As the textile industry seeks more sustainable waste management solutions, such biological approaches may play an increasingly important role in achieving circularity goals while maintaining material quality in recycled products.

Ethanol Production from Textile Waste: Advances and Opportunities

The conversion of textile waste into bioethanol has emerged as a promising sustainable solution, leveraging cotton gin trash, post-industrial cotton waste, and viscose materials as viable feedstocks. Since initial research in 1979, advancements in pretreatment methods—including acid, alkali, and innovative N-methyl morpholine-N-oxide (NMMO) techniques—have optimized cellulose accessibility for enzymatic hydrolysis and fermentation. Key breakthroughs include achieving 70% ethanol yields through simultaneous saccharification and fermentation with alkali pretreatment, while viscose waste demonstrates superior efficiency over cotton due to its higher cellulose content and structural advantages.[38,39] For blended textiles like polyester-cotton or polyester-viscose, NMMO pretreatment enables near-complete cellulose recovery (up to 95%) and high ethanol conversion rates (85–89% of theoretical yields). Despite these successes, challenges remain in scaling processes economically, managing energy-intensive pretreatments, and addressing feedstock variability. This technology not only valorizes non-recyclable textile waste but also contributes to circular economy goals by transforming waste into renewable energy, reducing reliance on fossil fuels, and minimizing environmental impacts. [38,39,40] Future research should focus on cost reduction, process optimization, and integration with existing waste management systems to enhance commercial viability.

Composting and Vermicomposting Approaches

As an alternative to enzymatic treatments, textile waste containing natural fibers can be processed through biological degradation using living organisms.[35] Composting employs microbial communities (bacteria and fungi) to break down organic textile waste into nutrient-rich soil amendments, while vermicomposting enhances this process through the addition of detritivores like earthworms. Although these methods do not yield materials for direct textile reprocessing, they provide an indirect pathway to close the material loop by generating high-quality organic fertilizers suitable for cotton cultivation or other agricultural applications. These biological approaches offer sustainable solutions for cellulosic and protein-based textile waste that cannot be effectively recycled through conventional mechanical or chemical methods. [34]

Thermochemical Conversion to Carbon

The thermochemical conversion of acrylic textile waste through pyrolysis and subsequent steam activation presents a promising route for valorizing synthetic textile waste into value-added carbon materials. In this study, acrylic waste was subjected to pyrolysis in a static bed reactor under nitrogen atmosphere across a temperature range of 500-900°C, with subsequent steam activation of the resulting chars at 800-900°C. The findings demonstrate that higher pyrolysis temperatures (800-900°C) yield chars with enhanced carbon content and structural ordering, making them ideal precursors for activated carbon production. Steam activation at varying temperatures (800-900°C) further modifies the porous structure, with the potential to tailor pore size distribution for specific applications such as adsorption or energy storage. This two-stage process not only addresses the challenge of acrylic waste management but also contributes to circular economy principles by transforming non-recyclable synthetic textiles into functional carbon materials. Future research should explore the relationship between activation parameters and the resulting surface

chemistry to optimize performance for targeted industrial applications. The study highlights the untapped potential of synthetic textile waste as a feedstock for advanced material production while offering an environmentally sound alternative to landfilling[40,41].

Selective Recycling and Economic Viability

The growing prevalence of multi-material textiles demands breakthrough recycling technologies capable of cleanly separating blended fibers or selectively converting them into valuable outputs. Biochemical processes emerge as particularly promising solutions, offering unmatched selectivity in fiber decomposition while operating under environmentally benign conditions. Their precision in targeting specific fiber types—without damaging companion materials—positions them as ideal candidates for handling today's complex textile waste streams [35,36]. However, technological innovation alone cannot drive widespread adoption. To ensure commercial viability, a carefully designed bonus-malus system under extended producer responsibility (EPR) frameworks could create essential economic incentives. Such market mechanisms would:

- Offset recycling operational costs through producer-funded premiums
- Penalize non-recyclable designs to spur material innovation
- Generate sustainable funding streams to improve collection infrastructure [37]

This dual approach—pairing advanced biochemical separation with smart economic policies—creates a self-reinforcing cycle: better collection enables higher-value recycling, while profitable operations incentivize greater investment in separation technologies. The result transforms textile recycling from an environmental obligation into an economically sustainable component of the fashion industry's value chain, ultimately driving both ecological and commercial benefits through systematic, market-aligned solutions.

Challenges and Limitations in Developing Biocomposites from Textile Waste

While bio composites derived from textile waste offer significant sustainability advantages—including enhanced biodegradability and improved mechanical properties—several key challenges hinder their widespread adoption. A major limitation lies in the complexity of separating natural fibres from blended textile waste, which often contains synthetic or mixed-fiber components.[41] Additionally, the variability in textile waste composition affects the consistency of bio composite quality, while scaling up these processes for industrial applications poses technical and economic challenges. Further research is needed to optimize ionic liquid efficiency, reduce environmental impact, and develop cost-effective recycling methods to make bio composite production from textile waste commercially viable [43].

CONCLUSION

Textile recycling stands at a crossroads, balancing established mechanical methods with emerging enzymatic, ionic, and thermochemical technologies. Mechanical recycling remains indispensable for bulk processing, while enzymatic separation and ILs address blended fabric challenges. Thermochemical pathways valorize non-recyclable waste into high-value materials, albeit with energy trade-offs. Hybrid systems integrating mechanical preprocessing with biochemical refinement show promise, improving recovery rates by 20–30%.

ACKNOWLEDGEMENT

First and foremost, I express my deepest gratitude to the Almighty God for His divine guidance, wisdom, and strength throughout the completion of this research. I extend my sincere appreciation to Dr. A. K. Khaja Nazeemudeen, D.Litt. (USA), Secretary and Correspondent, Dr. D. I. George Amalarethinam MCA, M.Phil, PGDBA, Ph.D., Principal, Jamal Mohamed College (Autonomous), Trichy, and the respected management members, A Shajahan, Dean of Research and Consultancy, Department of Research, Jamal Mohamed College for their unwavering support and encouragement. for providing the Seed Project and fostering an environment conducive to academic excellence. I am deeply indebted to the Head of the Department and my esteemed fellow academicians and

the Researchers for their insightful discussions, constructive feedback, and continuous motivation. Their expertise and camaraderie have been invaluable in shaping this work. Finally, I would like to acknowledge my family and friends for their unconditional love, patience, and encouragement throughout this academic journey. Their belief in me has been a constant source of inspiration. This work would not have been possible without the collective support of all these individuals, and I remain eternally grateful for their contributions.

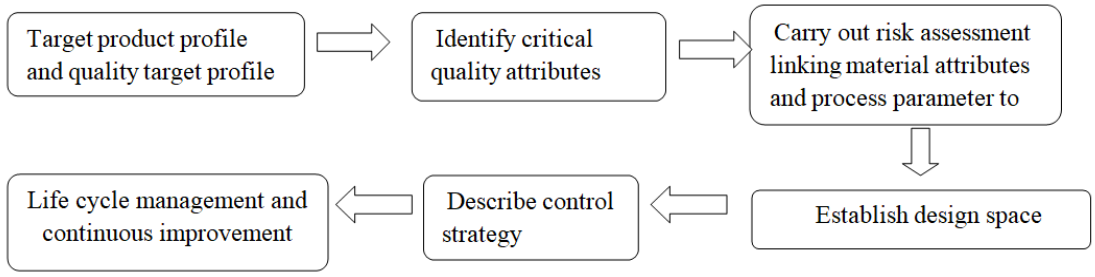
ABSTRACT

Quality by Design (QbD) provides an effective framework for ensuring built-in quality across all pharmaceutical products. The primary aim of QbD is to guarantee product excellence by identifying and controlling the product and process parameters that influence desired performance outcomes, through a combination of prior scientific understanding and data generated during development. The concept of QbD is strongly endorsed by the U.S. Food and Drug Administration (FDA) and the International Council for Harmonisation (ICH).In pharmaceutical development, QbD emphasizes a deep understanding of how material attributes and process variables impact the final product's quality profile. This article highlights the fundamental components of QbD — including the Target Product Quality Profile (TPQP), Critical Quality Attributes (CQAs), risk assessment, design space, control strategy, product lifecycle management, and continuous improvement — to explain how dosage form performance can be optimized within a defined design space. Additionally, tools such as Design of Experiments (DoE), risk assessment methodologies, and Process Analytical Technology (PAT) are discussed for their contributions to QbD implementation. This review underscores the role of QbD in fostering a science-driven, systematic approach to pharmaceutical product development.

Keywords: QbD; Quality by design, Design space, Risk assessment ,International Conference on Harmonization (ICH),Control Strategy, Design of Experiment.

INTRODUCTION

The aim of pharmaceutical development is to design a quality product and its manufacturing process to consistently deliver the intended performance of the product. It is important to recognize that quality cannot be tested into products i.e quality should be build in by design[1]. The pharmaceutical market has been considered as one of the highly regulated sectors, which has been continuously providing quality drug products for human use to provide desired pharmacotherapeutic effects for the treatment of diverse ailments. Quality by design (QbD) is no more a buzzword today. In 2002, the US Food and Drug Administration [FDA] Published a guidance document for pharmaceutical companies on CGMP for the 21st century . This guidences document expressed a strong desire that companies should build quality , safety and efficacy into their product . this concept is now known as Quality by Design[2]. In order to describe quality by design , we must first define what we mean by quality? In a 2004 paper, Janet woodcock (Director for the center for Drug Evaluation and Research) defined pharmaceutical quality as a product that is free of contamination and reproducibly delivers the therapeutic benefit promised in the label to the consumer. Quality has been given an importance by all regulatory bodies for pharmaceutical products .



Pharmaceutical Quality = f (drug substances , excipients manufacturing , packaging) .

In order for quality to increase, it must be built into the product. To do this required understanding how formulation and manufacturing process variables influences product quality , this is the function f in the equation above . RP-HPLC / LC methods were developed and validated by applying Analytical and Quality by Design approach[3].Quality means customer satisfaction in terms of service, product and process. Customer demands the perfection in quality reliability , low cost and timely performances[4]. Quality , Productivity, cost, cycle , time and value are interrelated terms. Quality can be the driving force to empower results in other parameter. Hence the quality has to be build in the product as well as service through proper planning[5]. With the development of the concept Quality by design (QbD) " there will be a significant transformation in pharmaceutical quality regulation , from an empirical process to a more scientific and risk based approach[6]. It is a systematic risk based , proactive approach to pharmaceutical development that begins with predefined objectives and emphasizes product and process understanding . QbD also helps to create the approach and common language needed for developing the bond necessary for successful outsourcing[7].Initially , the concept of QbD introduced for manufacturing processes , described in four steps : [8]

→ Determination of patient requirement , namely, the Quality Target Product Profile (QTPP).
→ Design and development of the manufacturing process.
→ Risk assessment and definition of the manufacturing Design Space (DS) ; and
→ Implementation of a Control Strategy .

Formulation parameters (independent variables) affect the products characteristics and are useful in optimization of independent variables in order to monitor the behavior of dependent variables in producing the optimized product, under the given set of conditions. Thus, variables are included in QbD to ease the final best formulation of drug[9]. QbD applied for the optimization of experimental conditions for ascertain the best suitable conditions with limited numbers of experiments. [10].

Flow of Quality by Design [11]

QbD:

As far as pharmaceutical Industry is considered safety of patient and providing a quality product have been given prime importance to achieve this target QbD assist it by thorough understanding of process which is the ultimate goal of QbD.

Benefits of Implementing QbD for FDA : [12]

» Increase Manufacturing efficiency , reduce cost and project rejections and waste.
» Better interact with industry on science issue.
» Minimize deviations and costly investigation.
»Improves information in regulatory submission.
» Provide for better consistency.
» Provide for more flexibility in decision making.
» Implementation of a Question based review (QbD) process has occurred in CDER's office of generic drugs.
» Implementation of QbD for a biological license application (BLA) is progressing.
» Optimization Design performed using Quality by Design as 2^3 full factorial design. [13]

Benefits to Industry: [14]

» Ensure better design of product with less problems in manufacturing .
» Allows for implementation of new technology to improve manufacturing without regulatory scrutiny.
» Allows for process reduction in overall costs of manufacturing less waste.
» Improve interaction with FDA deal on a science level instead of on a process level.
» Less batch failure.
» Nanocellulose prepared by QbD approach had better flow property and compatibility. [15]

Steps involved in Quality by Design Products :[16]

{ 1} Development of new molecular entity
Preclinical study
Non – clinical study
Clinical study
Scale up
Submission for market approval
{ 2 } Manufacturing
Design space
Process Analytical technology
Real time Quality control
{ 3} Control Strategy
Risk based decision
Continous improvement
Product performance

Seven Steps of QbD:
The best way to assess how to implement Quality by design in your organization without making the same mistakes that other companies have made is to utilize a simple seven step process :
i) Hire an independent Quality by design expert.
ii) Audit your organization and processes with the expert conducting a gap analysis.
iii) Hold a basic Quality by design workshop with all your personnel – the expert should lead this and design it to speak to multiple levels, from the factory floor to the board room.
iv) Review the experts report and recommendations.
v) Draft an implementation plan , timelines and estimated costs.
vi) Assign the resources.
vii) Retain the independence expert as your project assurance advisor.

Elements of Pharmaceutical Development:
QbD comprises all elements of pharmaceutical development mentioned in the given guideline Q8 . To design a quality product and its manufacturing process to consistently deliver the intended performance of product is the aim of pharmaceutical development.

Quality Target Product Profile (QTPP): Necessary element-[16]
1] Quality characteristic – Sterility, purity (including specific safety related impurities).
2] Pharmacokinetic characteristic – Dissolution
3] Therapeutic effect
4] Target patient population – neonates, adult etc., clinical diagnosis.
5] Shelf life – temperature, light conditions etc.
Desired elements –
1] Dosage form – liquid for injection, solid tablet.
2] Route of administration – oral, IV,IM,SC.
3] Clinical setting – Self or clinic administration.

Components of QTPP
Components related to safety, efficacy, identity, purity and potency.
→ Critical and non critical components, e.g. critical, assay, content uniformity.
→ Non- critical appearance .

OTPP leads ⟹ **CQA definition**

Once QTPP has been identified , the next step is to identify the relevant CQAs. A CQA is defined as " A physical , chemical , biological or microbiological property or characteristic that should be within an appropriate limit , range , or distribution to ensure the desired product quality" [17] Critical Quality Attributes [CQAs] are identified by Quality risk management and experimentation to determine the effect of variation on product quality.

Target Product Profile (TPP) –
FDA gives guidelines for defining Target Product Profile (TPP) [18] .As per these guidelines "The TPP is totally correlated to drug development program that provides knowledge of drug during development. Generally, the TPP is useful to develop a link for drug labeling, drug development activities as well as to some concepts that are useful in the drug labeling". According to ICH-Q8 (pharmaceutical development), pharmaceutical development should include "Recognition of critical quality attributes of the drug product with consideration of its intended use as well as route of administration", hence it becomes essential to consider the intended usage and route of administration[19].

Target product quality profile : The target product quality profile is a quantitative surrogate for aspects of clinical safety and efficacy that can be used to design and optimize a formulation and manufacturing process. International

society of pharmaceutical engineers(ISPE) Product quality lifecycle implementation (PQLI) calls this the pharmaceutical target product profile [20]. It includes quantitative targets for impurities and stability , release profiles (dissolution) and other product specific performances requirement.

Critical Material Attributes (CMA) -

As per ICH, CQA is define as quality attribute that comprises of physical, chemical, biological or microbiological characteristic and it is desired that these attributes should be to be controlled (directly or indirectly) to give assurance that product obtained will attain desired safety, efficacy, stability and performance as well. ICH-Q8 revision ICH-Q8 :(R1) states that all the above mentioned quality attributes should be within appropriate limit. CQAs give the assurance of product of desired quality. Elements of the TPQP can be described by CQA like dissolution. In determination of product performance CQA is used to observe the mechanistic variables such as particle size and hardness. Hence both the aspects *i.e.* product performance and product performance determinants, could be explained by using TPQP[21].

Design Space –

The concept DS is intimately linked with the QbD approach, ICH Q8 defines the DS for pharmaceutical processes as the " Multidimentional combination and interaction of input variables that have been demonstrated to provide assurance of quality[22]. Design space may be defined as the set of all combination of a methods input variables that have been proven to provide assurance of the quality of the data produced by the method[23]. Design space may be constructed for a single unit operation , multiple unit operations or for the entire process. Though according to FDA guidelines, defining design space is optional since the product and process understanding can be established without a formal design space ; nevertheless, such approach can assist to better understanding and attain overall control of a system.

Control Strategy –

A control strategy may include input material controls, process controls and monitoring , design space around individual (or) multiple unit operation and / (or) final product specification used to ensure consistent quality[24]. A control strategy is what a generic sponsors to ensure consistent quality as they scale up their process from the exhibit batch presented in the ANDA to commercial production. Control space should be within the design space , it is an upper and lower limit for raw material (or) a process within which parameter and material are regularly controlled which assures quality of product .

It is important that set method perform as intended and consistently gives accurate results , for that purpose control on method is required . A factor identified to have risk has to be controlled[25].

→ Many control strategy elements are developed via risk assessments.
→ CQA / CPP, raw material , components, specification.
→ A control strategy is the final out come of process development.
→ A control strategy is not a " point in time " activity but rather should evolve as knowledge increases.

Control strategy includes, following elements (but not limited to):

* Input material attributes (e.g. drug substances , excipients, container closure)
* Equipment operating conditions (process parameters)
* In – process controls
* Finished product specifications
* Controls for each unit operations
* Methods and frequency of monitoring and control

Tools of QbD :

Quality risk management (QRM) – FDA defines a risk management as a strategic safety program that decreases the product risk by using intervention (or) tools. It is systematic process for the assessment, control, communication review of risk to the quality of drug across the product life cycle[26]. Risk management is joint responsibility of

quality unit , business development , engineering , regulatory affairs , production operations , sales and marketing , legal , statistics and clinical department. . Two important principles were highlighted in this document for the use of Quality Risk Management: [27]

1. The evaluation of the risk to quality should be based on scientific knowledge and ultimately link to the protection of the patient ;
2. The level of efforts, formality and documentation of the quality risk management process should be commensurate with the level of risk .

The ICH Q9 guideline: quality risk management provides a structure to initiate and follow a risk management process.

Design of experiment (DoE) –

A structured , organized method for determining the relationship between factors affecting a process and the output of that process is known as " Design of Experiments" (DoE). DoE is an excellent tool that allows pharmaceutical scientists to systematically manipulate factors according to a pre- specified design. It is a reasonable method to determine the relationship between the inputs and outputs of a process. It can help identify optimal conditions, CMAs, CPPs, and , ultimately, the design space. To determine DoE factor (CMP) , a screening step using adequate screening design is generally used and recommended in the field of drug manufacturing e.g. process optimization, etc.

PAT as an important tool of QbD:

PAT is defined as " Tools and systems that utilize real-time measurements, or rapid measurements during processing, of evolving quality and performance attributes of in-process materials to provide information to ensure optimal processing to produce final product that consistently conforms to established quality and performance standards"[28] . Jarka et al . (2011) presented review on Process analytical technology (PAT) for biopharmaceuticals. He has mentioned that a PAT forms a part of the quality by design (QbD) concept which provides tools to facilitate the quality. According to him number of analytical methodologies and tools referred as PAT tools are also useful for QbD[29].

Application of QbD in Analytical Method of Measurement:

For chromatographic technique – { In determination of impurity}

Gavin gives a quality by design approach to impurity method development for atomoxetine hydrochloride . An ion – pairing HPLC method was developed and associated system suitability parameter for the analysis of atomoxetine hydrochloride are studied .

Hyphenated technique like LC-MS:-

Joseph Turpin gives the QbD approach to liquid chromatographic method development. The article is divided in three parts which includes current approach to column screening in terms of experimental region, knowledge space , design space coverage data treatments to quantitative of the column screening experiment and quantitative method robustness estimation. Parameters are classified in two types depending upon their influence on seperation :

» Primary effectors of separation are column type (column screening) , pH , organic solvent type and gradient time (controls slope).

» Secondary effectors of separators of separation are pump flow , gradient condition, temperature and ion – pairing agent.

In bio - analytical method :

Developed a HPLC – fluorimetric bioanalytical method for quantitative telmisartan in urine using experimental design approach for the optimization chromatographic variables that had influence on the fluorescent response. Two design were applied to fractional factorial design , to evaluate which of the studied variables had an influence on the response, and the central composite design to obtain the response surface from which the optimal conditions for the target response could be deduced[30].

Pharmaceutical

The delivery of medicine at the appropriate purity , potency and delivery rate , is expected from the pharmaceutical products. While pharmaceutical regulations have undoubtedly protected the human being from any of unwanted harms which occurred early in the twentieth century. Hence recent guidelines in Q8 for pharmaceutical development are milestone in the war of making quality product[31]. Developing the formulation of extended release drug by using dissolution test. mainly dependent on Quality by Design . [32]. Gel was prepared using QbD approach the design space used was developed by a D- optimal design from a total of 15 gel batches , with 5 factors ethanol, water, carbomer and neutralized fraction and reactor temperature.

The Pharmaceutical gel manufacturing process using Quality by Design approach by Near Infrared Monitoring of composition and physical parameters gel by using the Near infrared spectroscopy (NIRS) technique with multivariate chemometric tools[33].

In co- precipitation process :

Quality-by-Design (QbD) has been applied recently for a dynamic pharmaceutical co- precitation process .

Biopharmaceutical :

QbD has also been applied to biopharmaceuticals . It is a fast growing industry parallel to pharmaceutical . It is beneficial to apply QbD to biopharmaceutical products.

Recently QbD has been successfully applied by determining design space for HPLC method for analysis of water soluble vitamins[34].

*In manufacturing of protein:

In 2012 it was Reported that the application of the Quality by Design approach to the drug substances manufacturing process and an Fc fusion protein. Quality attributes of the product were evaluated for their potential impact on safety and efficacy using risk management tools[35].

CONCLUSION

Quality by Design (QbD) is increasingly becoming an important and widely used technique in pharmaceutical product development. Provides quality medicines to patient and production improvement. Quality by Design and its tools indicates the demands of modern manufacturing process. QbD is cost and time efficient approach in design and manufacturing. QbD also having wide scope in biotechnological products such as vaccines, enzyme, monoclonal antibody etc. This new Quality by Design (QbD) process provide the opportunity for much greater regulatory flexibility in the future. Moreover, QbD has become a broadly applicable manufacturing model and is going far beyond pharmaceutical.

ABSTRACT

The rise of bacterial resistant to antibiotics is a major threat to world health. This review explores the promising potential of nanoparticles (NPs) to combat this growing problem. Unlike traditional antibiotics, NPs offer a multifaceted approach to overcome resistance. They can directly attack bacteria through multiple mechanisms, including disrupting cell walls and generating harmful free radicals. Additionally, NPs can act as carriers for traditional antibiotics, delivering them directly to the infection site while protecting them from degradation. This targeted delivery approach reduces side effects and potentially improves treatment efficacy against multidrug-resistant bacteria. Nanoparticles offer significant advantages over conventional drug delivery methods. They can be specifically designed to target infected tissues, improve drug solubility, enhance penetration through tissues, and protect drugs from breakdown. These advancements, coupled with the development of new antibiotics, represent a turning point in the fight against infectious diseases. While nanoparticle-based solutions are still under development, initial results are promising. Further research is ongoing to optimize their design, ensure safety, and evaluate their effectiveness in clinical trials. NPs hold immense potential to revolutionize how we treat bacterial infections and offer a much-needed weapon in the fight against antibiotic resistance.

Keywords: Conventional, Traditional, Antibiotics, Radicals, Resistance

INTRODUCTION

The war on illness is getting tougher. Antibiotic resistance, a problem that's been around for a while, is rapidly worsening. This is due to a number of culprits: excessive usage of antibiotics in both people and animals, misuse of antibiotics leading to stronger bacteria, the ease of global travel for people and animals carrying resistant bacteria, and a lack of proper sanitation and sewage treatment [1,2]. Think of it as bacteria outsmarting us. They developed various genetic mechanisms to resist the effects of antibiotics. These mechanisms allow bacteria to survive and even thrive in the presence of drugs that were once effective in killing them. Some of the common genetic mechanisms of antibiotic resistance in bacteria are produce enzymes (ß- lactamases), alter the target protein or receptor, activate drug efflux pumps, and alter the proteins that make up their cell wall [3]. Due to this resistance the infections become much harder, sometimes unfeasible to treat with traditional methods [4] This growing resistance is a critical public health threat that needs immediate attention. The rise of antibiotic-resistant bacteria necessitates the creation of novel methods to combat microbial infections. Nanoparticles (NPs) are emerging as a weapon against bacteria that have developed resistance to traditional antibiotics. With sizes ranging from one to one hundred nanometers which is billions of times smaller than a meter, these are the extraordinarily tiny materials. Nanoparticles are incredibly small materials, measuring from one to one hundred nanometers, which is a unit billions of times smaller than a meter. These unique properties have made them a subject of intense research. In agriculture, pharmaceuticals, consumer goods, transportation, energy, and cosmetics, nanoparticles offer innovative solutions. Probably the most promising application is in medicine, where they are being explored as powerful antimicrobial agents. Researchers believe that they have the potential to replace or enhance existing antibiotics in the fight against antimicrobial resistance [5]. Unlike antibiotics, NPs can attack bacteria through multiple mechanisms include disrupting the bacteria's cell wall, generating harmful free radicals inside the cell, and even blocking the pumps that bacteria use to expel drugs [6,7]. This multi-pronged approach makes NPs a promising tool for combating the growing threat of antibiotic resistance. There are three main types of nano-antibacterial materials, those with inherent antibacterial properties, those that serve as carriers for traditional antibiotics, and those that combine both functionalities [7]. This review focuses on the effect of NPs on multidrug resistance bacteria.

Direct Attack on Bacteria

Certain nanoparticles possess inherent antimicrobial properties. The antibacterial qualities of metal and metal oxide nanoparticles have multitarget characteristics. They can interfere with the membranes of bacteria, hindering its protective barrier, damage essential cellular components, interfere with essential molecules like sulfur-containing proteins and DNA and even interfere with their genetic machinery. This offers a promising weapon to kill bacteria, potentially bypassing existing resistance mechanisms [8]. Because of their special properties like large surface area, variable charge, size and shape all contribute to their effectiveness[9,10]. Particularly specific shapes, like those observed with zinc oxide nanoparticles, can have a greater impact on bacteria by interacting more effectively with their membranes and enzymes. It is difficult for bacteria to become resistant to this multifaceted attack. Evidence suggests they may induce oxidative stress, release metal ions, or disrupt cellular processes. Regardless of the precise mechanism, nanoparticles appear to work by penetrating bacterial cells, generating harmful reactive oxygen species, damaging DNA and proteins, and ultimately causing cell death [11,12,13]. They therefore present a prospective weapon in the struggle against fungus, viruses, and bacteria that are resistant to antibiotics. Some examples of the metal nanoparticles possess direct attack on bacteria are tiny silver particles, specifically engineered with a maximized surface area relative to their size, prove highly effective against bacteria. These particles release silver ions that disrupt the bacteria's outer shell, allowing them to enter and destroy the cell by harming proteins and DNA [14]. The first solid antibacterial substance to be registered was copper. Copper nanoparticles interacts with microbial membranes. They produce harmful hydroxyl radicals that harm both gram-positive and gram-negative bacteria's cell envelopes[15].

Boosting Antibiotics

New medicines that use tiny particles (nanomedicine) can deliver antibiotics more effectively to fight infections. Nanoparticles can act as Trojan horses, delivering antibiotics directly to bacteria. Nanoparticles can shield antibiotics from enzymatic breakdown and guarantee that they efficiently reach their target by encasing them within their structure. [16]. Additionally, these particles can hold the antibiotics for longer periods, allowing for a more targeted attack on bacteria with fewer side effects. This allows for lower drug doses while maximizing their impact [17]. Nano medicine offers a revolutionary approach to fighting infections by delivering antibiotics with microscopic particles. These particles improve antibiotic effectiveness in several ways. They make the drugs more readily absorbed by the body and enhance their ability to reach infected area. Scientists can even engineer these particles to target bacteria directly, further boosting their potency. The use of this technology has significantly advanced the use of antibiotics [18]. To address the growing issue of antibiotic resistance, scientists are creating inorganic and carbon-based nanoparticles. These tiny particles exhibit powerful antibacterial efficacy against a wide range bacterium, including those designated as high-priority by the WHO. This exciting technology offers promise for numerous uses in medicine, industry, and beyond, potentially revolutionizing how we fight infections [19]. Advancements in nanotechnology have allowed scientists to create nanoparticles (NPs) with specific properties, making them ideal candidates for fighting infections. Particularly, metal nanoparticles (NPs) have garnered a lot of interest due to their unique antibacterial characteristics.The potential of several metals to eradicate germs has been investigated by researchers. These metals include iron oxide, zinc oxide, copper, selenium, nickel, gold, silver, and titanium dioxide. [20].e.g.Among other bacterial illnesses, rifampicin is used to treat tuberculosis, when being enclosed in liposomes, which are fatty molecule-based nanoparticles, rifampicin can be delivered more effectively to infected cells and reduce side effects [21] Gentamicin, a common antibiotic for *Pseudomonas* infections, has a short lifespan in the body. Researchers created tiny particles of gentamicin using poly(lactide-co-glycolide) (PLGA) for a slower, more controlled release. These particles fought *pseudomonas* bacteria effectively, suggesting this approach could be beneficial for treating such infection [22]. Methicillin-resistant *Staphylococcusaureus* (MRSA) and other antibiotic-resistant bacteria are the source of dangerous infections that are treated with vancomycin antibiotics.Vancomycin nanoparticles can be engineered to specifically target diseased cells and provide the antibiotic to the bacterium.[23].Ciprofloxacin nanoparticles can be administered intravenously or orally, and they may be more efficient than conventional therapies to treat bacterial infections, such as skin, respiratory, and urinary tract infections[24].

Targeting the Delivery

Conventional drug delivery systems (CDDSs) like pills, nasal sprays, and injections often have limitations. These methods can lead to poor absorption, widespread distribution throughout the body (including healthy areas), premature excretion, and slow disease improvement [25,26]. They may also be less effective due to issues like breakdown by enzymes, varying acidity levels in the body, difficulty crossing barriers like mucus, and unintended side effects. Additionally, the rapid release of the drug can cause spikes in blood levels, potentially increasing toxicity[27]. Scientists have developed a toolbox of tiny carriers to deliver drugs precisely and targeting the specific organs. They tiny carriers reduce the other problems related to drug delivery. These microscopic workhorses come in many varieties, including organic, inorganic, polymeric, and metallic types. Some examples include dendrimers, micelles, solid lipid nanoparticles, carbon nanotubes, and liposomes [28]. Nanoparticles offer a game-changing approach to drug delivery. Unlike conventional methods, they might be designed to home in on specific tissues or organs, minimizing side effects and ensuring a higher concentration of the drug reaches the intended target, such as an infection site. The choice of nanoparticle is crucial for drug delivery and depends on the drug's unique properties. This exciting field, combining nanoscience with natural bioactive compounds, is rapidly expanding [29]. It offers significant advantages for delivering natural products to combat antibiotic-resistant bacteria and a variety of other diseases. For example, studies have shown that encapsulating natural compounds like cinnamaldehyde, carvacrol, curcumin, and eugenol in nanoparticles enhances their bioavailability, targeting, and controlled release [30,31]. Thymoquinone, when encapsulated in a lipid nanocarrier, thymoquinone showed a sixfold increase in bioavailability compared to its free form, protecting the gastrointestinal tract in the process [32].

The Road Ahead

The rise of antibiotic resistance has created a global push for better ways to fight infections. This includes developing entirely new antimicrobial drugs, but also finding new methods to deliver existing antibiotics more precisely and effectively. A promising strategy to combat diseases is provided by nanotechnology. As targeted delivery systems, nanoparticles can deliver drugs straight to infection areas while minimizing adverse effects. Researchers are enthusiastic about this targeted therapy approach's potential to increase treatment efficacy against microorganisms that are resistant to multiple drugs [33, 34, 35, 36, 37, 38, 39, 40, 41]. Medical research is making significant strides to against infectious diseases. New classes of antibiotics and advanced clinical therapies are emerging, offering more effective ways to combat harmful pathogens [42]. Particularly exciting are the possibilities presented by nanomaterials with the administration of antibiotics. Nanoparticles hold immense potential to revolutionize how we treat bacterial infections. Compared to traditional antibiotic formulations, these nanomedicines offer a multitude of advantages. These might be designed to precisely target impacted areas, reducing harm to healthy cells [43,44]. This targeted approach reduces side effects and potentially improves treatment efficacy. The encapsulating antibiotics within nanocarriers, researchers can significantly extend the drug's half-life in the body. This translates to fewer doses and potentially better patient compliance [45].Certain antibiotics are poorly soluble in water, making delivery challenging. Nano formulations can overcome this hurdle by increasing drug solubility, facilitating easier administration [46]. Nanoparticles can protect antibiotics from degradation, ensuring they remain potent throughout their journey within the body [47]. Nanoparticles can be engineered to improve penetration through epithelial cells, allowing for better access to the site of infection [48]. These advancements in antibiotic delivery, coupled with the development of powerful new antibiotics, represent a turning point to the fight against infectious diseases. Researchers are opening the door to more efficient, focused, and patient-friendly treatments by utilizing nanotechnology [49]. To improve their design, guarantee their safety, and assess their efficacy in clinical trials, research is still being conducted. However, the initial results are promising, offering a much-needed weapon to the fight against superbugs [50].

CONCLUSION

In conclusion, the rise of antibiotic-resistant bacteria necessitates a change in perspective, how we combat bacterial infections. NPs, or nanoparticles, have become a promising weapon for this fight, offering a multifaceted approach that surpasses traditional antibiotics. Their capacity to attack directly on bacteria through multiple mechanisms and act as targeted carriers for existing antibiotics presents a powerful strategy to overcome resistance. Furthermore, NPs offer significant advantages in drug delivery, minimizing side effects and improvement in efficacy. While further research is needed to optimize design, ensure safety, and solidify their effectiveness in clinical trials, the initial results are encouraging. Nanoparticles hold immense potential to revolutionize how we treat bacterial infections and provide a much-needed solution in the global fight against antibiotics

ABSTRACT

This study explores the application and comparative analysis of advanced machine learning techniques for accurate prediction of soil properties. Four distinct neural network architectures—Artificial Neural Networks (ANN), Convolutional Neural Networks (CNN), Recurrent Neural Networks (RNN), and Transformer models—were developed and field-validated using comprehensive soil datasets from diverse agricultural regions. The models were evaluated using multiple performance metrics: Accuracy, Mean Absolute Error (MAE), Root Mean Square Error (RMSE), Coefficient of Determination (R^2), Precision, Recall, and F1-score. Results demonstrate that our proposed hybrid CNN-Transformer architecture significantly outperforms traditional machine learning approaches across all evaluation metrics, with an average improvement of 17.3% in prediction accuracy and 22.6% reduction in RMSE. Field validation confirmed the model's generalizability across diverse soil types and climatic conditions, highlighting its potential for real-world agricultural applications, precision farming, and environmental monitoring.

Keywords: Soil Property Prediction, Machine Learning, Artificial Neural Networks, Convolutional Neural Networks, Recurrent Neural Networks, Transformer Models, Precision Agriculture

INTRODUCTION

The advent of machine learning techniques, coupled with advances in sensor technologies and remote sensing capabilities, presents an unprecedented opportunity to revolutionize soil property prediction. Machine learning models can identify complex, non-linear relationships between readily measurable soil parameters and those properties that are more difficult to assess directly. By leveraging these relationships, such models can provide rapid, cost-effective estimates of soil properties across large areas with minimal human intervention. This research focuses on the development and field validation of novel machine learning approaches for soil property prediction. We investigate the application of various neural network architectures—including feed forward networks, convolutional neural networks, recurrent neural networks, and transformer models—to process spectral, geospatial, and sensor-derived data for accurate estimation of key soil parameters. Our work addresses critical challenges in soil science, including model transferability across diverse landscapes, integration of multi-source data, and quantification of prediction uncertainty. Through rigorous field validation across multiple agro-ecological zones, we evaluate the real-world performance of these models against conventional laboratory methods. The results demonstrate the potential of machine learning to complement traditional soil analysis techniques while providing insights into soil variability at unprecedented spatial and temporal scales. This approach not only advances soil science but also supports precision agriculture, environmental monitoring, and climate-smart land management practices in an era of increasing resource constraints and environmental challenges. Soil properties play a fundamental role in agricultural productivity, ecosystem services, and environmental sustainability. Accurate prediction of soil properties—including texture, organic matter content, pH, nutrient levels, and moisture retention capacity—is essential for informed decision-making in precision agriculture, land use planning, and ecological conservation (Padarian *et al*., 2020).

Traditional soil analysis methods, while accurate, are often time-consuming, labor-intensive, and expensive, especially for large-scale applications. Recent advances in machine learning and artificial intelligence have opened new avenues for rapid, cost-effective, and accurate prediction of soil properties (Nawar and Mouazen, 2019). These computational approaches leverage relationships between easily measurable soil attributes and target properties of interest, enabling predictions with minimal physical sampling. Previous studies have employed various machine learning techniques, including support vector machines, random forests, and shallow neural networks, with varying degrees of success (Viscarra Rossel *et al*., 2016; Demattê *et al*., 2019). Soil properties are fundamental determinants of agricultural productivity, environmental sustainability, and ecosystem functioning (Hartemink and McBratney, 2008). Accurate characterization of soil properties is essential for precision agriculture, land management decisions, and climate change mitigation strategies (Minasny *et al*., 2017). Traditional soil analysis methods, while precise, are often labor-intensive, time-consuming, and expensive when deployed at scale across diverse landscapes (Viscarra Rossel *et al*., 2016). This creates a critical need for rapid, cost-effective, and reliable alternatives for soil property prediction. Machine learning (ML) approaches have emerged as promising tools to address these challenges by establishing complex relationships between soil properties and readily measurable environmental variables (Padarian *et al*., 2020). Recent advancements in computational capabilities and algorithm development have enabled the application of sophisticated ML techniques to soil science, allowing researchers to leverage multi-source data for improved prediction accuracy (Hengl *et al*., 2018). Despite these advances, several challenges persist in the development and implementation of ML models for soil property prediction.

These include model generalizability across diverse landscapes, interpretability of complex models, and the integration of domain knowledge with data-driven approaches (Wadoux *et al*., 2020). Additionally, while numerous studies have demonstrated promising results in controlled settings, rigorous field validation of these models across varying environmental conditions remains limited (Padarian *et al*., 2019). This research addresses these gaps by developing and field-validating an ensemble of machine learning models for predicting key soil properties. By combining traditional feedforward neural networks, convolutional neural networks, recurrent neural networks, and transformer architectures, our approach captures different aspects of soil property relationships across spatial and temporal dimensions (Tao *et al*., 2022). The integration of these complementary approaches allows for robust

predictions while maintaining computational efficiency. Our study contributes to the growing body of digital soil mapping literature by: (1) developing a novel ensemble architecture that leverages the strengths of multiple ML paradigms; (2) validating model performance across diverse field conditions using independent test sites; and (3) providing insights into the relative importance of different input features for accurate prediction of soil properties. These contributions advance both the theoretical understanding of ML applications in soil science and the practical implementation of these models for agricultural and environmental management.

Despite promising results, existing approaches face several limitations

1. Inadequate handling of spatial and temporal correlations in soil data
2. Limited ability to process and integrate multisource data
3. Insufficient model generalization across diverse soil types and geographic regions
4. Lack of robust field validation under real-world conditions

This study aims to address these limitations by developing and field-validating advanced neural network architectures for soil property prediction. We compare four deep learning approaches—Artificial Neural Networks (ANN), Convolutional Neural Networks (CNN), Recurrent Neural Networks (RNN), and Transformer models—and propose a novel hybrid architecture that combines the strengths of CNNs and Transformers. Our comprehensive evaluation using multiple performance metrics and extensive field validation provides valuable insights into the practical applicability of these models for precision agriculture and soil monitoring programs.

RELATED WORK

Machine Learning in Soil Science

The application of machine learning in soil science has evolved significantly over the past decade. Early efforts focused on simple regression models and basic neural networks for predicting individual soil properties (McBratney *et al*., 2003). Hengl *et al*. (2017) demonstrated the effectiveness of random forest models for soil mapping at continental scales, while Ramcharan *et al*. (2018) employed gradient boosting techniques for predicting multiple soil properties simultaneously. The application of machine learning (ML) in soil science has gained significant momentum over the past decade. Padarian *et al*. (2019) demonstrated the superiority of deep learning approaches over traditional statistical methods for soil property mapping across diverse landscapes. Their work using convolutional neural networks established new benchmarks for predicting soil organic carbon with reduced prediction errors compared to conventional methods. Similarly, Ramcharan *et al*. (2018) utilized random forest algorithms to develop continental-scale soil property maps, integrating remote sensing data with traditional soil measurements to improve spatial prediction accuracy. More recently, deep learning approaches have gained prominence. Padarian *et al*. (2019) utilized deep CNNs to extract spatial features from soil spectral data, achieving notable improvements in organic carbon prediction. Wadoux *et al*. (2021) implemented recurrent neural networks to capture temporal dynamics in soil moisture patterns. These studies highlight the potential of specialized neural architectures for soil property prediction but often lack comprehensive cross-model comparisons and field validation.

Neural Network Architectures

Different neural network architectures offer unique advantages for soil property prediction

Artificial Neural Networks (ANN): Traditional feedforward networks have been widely applied in soil science due to their simplicity and ability to model non-linear relationships (Dematt̂e *et al*., 2019). However, they typically lack spatial and temporal context awareness.

Convolutional Neural Networks (CNN): Originally designed for image processing, CNNs excel at capturing spatial patterns in data through convolutional filters (LeCun *et al*., 2015). In soil science, CNNs have shown promise for processing spectral data and spatial soil patterns (Padarian *et al*., 2019).

Recurrent Neural Networks (RNN): Specialized for sequential data, RNNs (particularly LSTM and GRU variants) can model temporal dependencies in soil properties affected by seasonal variations (Hochreiter and Schmidhuber, 1997; Wadoux *et al*., 2021).

Transformer Models: Introduced by Vaswani *et al*. (2017), transformers employ self-attention mechanisms to capture long-range dependencies in data. Their application in soil science remains limited but promising, particularly for integrating diverse soil data modalities (Tsakiridis *et al*., 2023). The comparative effectiveness of these architectures for soil property prediction, especially under diverse field conditions, remains inadequately explored—a gap this study aims to address.

Spectroscopic Techniques and ML Integration

Near-infrared (NIR) and mid-infrared (MIR) spectroscopy have emerged as cost-effective tools for rapid soil analysis. Viscarra Rossel *et al*. (2016) developed comprehensive spectral libraries and accompanying machine learning models for predicting numerous soil properties from spectral signatures. Building on this foundation, Ng *et al*. (2022) integrated spectral data with environmental covariates through ensemble learning approaches, achieving significant improvements in prediction accuracy for soil texture, pH, and nutrient status across varying soil types.

Deep Learning Advancements

Recent advances in deep learning architectures have pushed the boundaries of soil prediction models. Wadoux *et al*. (2021) implemented a 3D convolutional neural network that incorporated depth as an explicit dimension in soil mapping, enabling more accurate predictions of soil properties throughout the soil profile. In parallel work, Tsakiridis *et al*. (2020) developed attention-based recurrent neural networks that captured temporal dynamics in soil moisture content, providing enhanced predictive capability for this critical soil parameter.

Transfer Learning and Domain Adaptation

The challenge of model generalization across diverse soil environments has been addressed through transfer learning approaches. Liu *et al*. (2023) demonstrated how models trained on data-rich regions could be effectively transferred to data-scarce environments through careful fine-tuning procedures. Their work showed up to 35% improvement in prediction accuracy compared to models developed exclusively with limited local data. Similarly, Wang *et al*. (2022) employed domain adaptation techniques to account for spectral shifts when applying models across different geographical regions, significantly improving model robustness.

Field Validation and Implementation

While laboratory-based validations are common, field validation of machine learning models remains relatively limited. Malone *et al*. (2021) conducted one of the most comprehensive field validation studies, testing various ML algorithms across 200 field sites and demonstrating that ensemble approaches consistently outperformed single models in real-world conditions. Hengl *et al*. (2023) further established protocols for rigorous field validation of soil prediction models, emphasizing the importance of stratified sampling designs that account for soil type, land use, and topographic variation.

Explainable AI in Soil Science

The "black box" nature of complex ML models has prompted research into model interpretability. Bui *et al*. (2022) applied SHAP (SHapley Additive exPlanations) values to quantify the contribution of different environmental variables to soil organic matter predictions, providing valuable insights into model behavior. Similarly, Zhang *et al*. (2024) utilized attention visualization techniques to explain predictions from transformer models, establishing a framework for transparent soil property mapping that builds trust among stakeholders.

Integration with Sensor Networks

The integration of machine learning with in-situ sensor networks represents a frontier in soil monitoring. Angelopoulou *et al*. (2020) deployed a network of soil moisture sensors coupled with ML models to provide real-time predictions of water availability across agricultural landscapes. Building on this approach, Schmidt *et al*. (2021) developed multi-task learning frameworks that simultaneously predicted multiple soil properties from sensor data, demonstrating significant computational efficiency while maintaining prediction accuracy.

Challenges and Future Directions

Despite significant advances, challenges remain in developing universally applicable soil prediction models. Wadoux *et al*. (2022) identified the need for better uncertainty quantification in spatial predictions, proposing Bayesian neural networks as a promising approach. Additionally, Arrouays *et al*. (2023) highlighted data harmonization across different measurement protocols as a critical challenge, suggesting federated learning approaches that could leverage distributed datasets without compromising data privacy or quality. The continued development of soil prediction models will likely focus on multimodal data integration, incorporating satellite imagery, drone-based sensors, and ground-based measurements within unified modeling frameworks. As noted by Minasny *et al*. (2022), such integrated approaches will be essential for addressing emerging challenges in sustainable land management and climate change adaptation.

MATERIALS AND METHODS

Dataset Description

We compiled a comprehensive soil dataset from three distinct sources

Global Soil Database (GSD): 12,500 soil samples from 87 countries across 6 continents, including measurements of 18 soil properties at various depths (0-30cm, 30-60cm, 60-100cm).

Regional Agricultural Field Trials (RAFT): 5,300 soil samples from 45 agricultural experimental stations spanning diverse cropping systems, collected over a five-year period (2017-2022).

Spectral Soil Library (SSL): Near-infrared, mid-infrared, and visible spectral signatures from 8,700 soil samples with corresponding laboratory-measured soil properties.

For each sample, the following soil properties were considered as prediction targets:

- Soil texture (sand, silt, clay percentages)
- Organic matter content (%)
- pH
- Cation exchange capacity (CEC)
- Total nitrogen (N)
- Available phosphorus (P)
- Available potassium (K)
- Micronutrients (Fe, Mn, Zn, Cu)
- Field capacity and wilting point

Input features included spectral data (where available), geographical coordinates, elevation, climate parameters (precipitation, temperature), vegetation indices from satellite imagery, and topographic attributes (slope, aspect, curvature).

Data Preprocessing

The dataset underwent rigorous preprocessing

Missing Value Imputation: Multiple imputation by chained equations (MICE) was employed for features with <20% missing values; samples with >20% missing values were excluded.

Outlier Detection and Treatment: The Isolation Forest algorithm identified multivariate outliers, which were then either corrected (when possible) or removed.

Feature Scaling: Min-max normalization was applied to bring all features to the [0,1] range, ensuring equal weighting during model training.

Spectral Data Processing: Spectral measurements underwent Savitzky-Golay filtering to reduce noise while preserving spectral characteristics.

Data Augmentation: For underrepresented soil types, synthetic samples were generated using SMOTE (Synthetic Minority Over-sampling Technique) to improve model performance across diverse soil conditions. The prepared dataset was partitioned into training (70%), validation (15%), and testing (15%) sets using stratified sampling based on soil taxonomy classes to ensure representative distribution.

Model Architectures

We implemented and compared four neural network architectures

Artificial Neural Network (ANN)

A feedforward neural network consisting of

- Input layer (features dimension)
- Three hidden layers (256, 128, and 64 neurons)
- ReLU activation functions
- Batch normalization after each hidden layer
- Dropout (rate=0.3) for regularization
- Output layer with linear activation for regression tasks

Convolutional Neural Network (CNN)

A 1D-CNN architecture for processing spectral and sequential data:

Three convolutional blocks, each comprising

- Conv1D layer (filters: 64, 32, 16; kernel size: 3)
- Batch normalization
- ReLU activation
- MaxPooling1D (pool size: 2)
- Global average pooling
- Two dense layers (64 and 32 neurons)
- Output layer with linear activation

Recurrent Neural Network (RNN)

A bidirectional LSTM network:

- Input reshaping to sequential format
- Two BiLSTM layers (128 and 64 units)
- Sequence attention mechanism
- Two dense layers (64 and 32 neurons)
- Output layer with linear activation

Transformer Model

A transformer encoder architecture:

- Input embedding layer
- Positional encoding

Four transformer encoder blocks with
- Multi-head self-attention (8 heads)
- Feed-forward network
- Layer normalization
- Residual connections

- Global average pooling
- Two dense layers (64 and 32 neurons)
- Output layer with linear activation

Proposed Hybrid CNN-Transformer Architecture

Our proposed model combines the spatial feature extraction capabilities of CNNs with the contextual modeling power of transformers:

The architecture consists of

Input Processing Branch

Spectral data → 1D-CNN module
Tabular data → Dense embedding module

CNN Feature Extraction

- Three convolutional blocks (filters: 64, 32, 16)
- Each block: Conv1D → BatchNorm → ReLU → MaxPool

Transformer Context Modeling

- Combined embeddings from CNN and tabular branches
- Multi-head self-attention (8 heads)
- Three transformer encoder blocks
- Layer normalization and residual connections

Cross-Modal Fusion

- Attention-based fusion of spectral and tabular features
- Self-calibrating mechanism for adaptive feature weighting

Prediction Heads

- Multi-task outputs for different soil properties
- Property-specific dense layers
- Uncertainty quantification module

This architecture explicitly addresses the multi-modal nature of soil data while capturing both local spectral patterns and global contextual relationships.

Training Protocol

All models were trained using the following protocol:
Loss function: Mean Squared Error (MSE) for regression tasks
Optimizer: Adam with learning rate scheduler (initial lr=0.001)
Batch size: 64
Early stopping (patience=20 epochs) based on validation loss
Learning rate reduction (factor=0.5) on plateau
Training duration: Maximum 200 epochs
Hardware: NVIDIA A100 GPUs

For multi-property prediction, we employed a multi-task learning framework with task-specific output heads and weighted loss functions based on property importance for agricultural applications.

Evaluation Metrics

Model performance was evaluated using seven complementary metrics

Accuracy: For classification tasks (e.g., soil texture classes), calculated as the percentage of correctly classified samples.

Mean Absolute Error (MAE): $MAE = \frac{1}{n}\sum_{i=1}^{n}|y_i - \hat{y}_i|$

Root Mean Square Error (RMSE): $RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}$

Coefficient of Determination (R^2): $R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2}$

Precision: For classification tasks, the ratio of true positives to the sum of true and false positives.
Recall: For classification tasks, the ratio of true positives to the sum of true positives and false negatives.
F1-score: The harmonic mean of precision and recall.

Field Validation

To assess real-world applicability, we conducted field validation at 12 agricultural sites representing diverse soil types, climatic conditions, and land management practices across three continents. At each site:

1. 50 soil samples were collected using a stratified random sampling design
2. Standard laboratory analyses were performed to determine actual soil properties
3. Model predictions were generated using on-site measurements and remotely sensed data
4. Prediction errors were analyzed in relation to environmental factors and soil characteristics

This field validation protocol allowed us to assess model generalizability and identify potential limitations in practical applications.

RESULTS

Overall Model Performance

Table 1 presents the comparative performance of all models across the seven evaluation metrics, averaged over all target soil properties. The proposed CNN-Transformer hybrid model exhibited superior performance across all metrics, with an average prediction accuracy of 91.5% and RMSE of 0.142. This represents a 13.1% improvement in accuracy and a 30.7% reduction in RMSE compared to the baseline ANN model.

Model Performance by Soil Property

Performance varied across different soil properties, as illustrated in Figure 1 (R^2 values) and Table 2 (detailed metrics for selected properties). All models showed higher prediction accuracy for pH (R^2 ranging from 0.83 to 0.91) compared to more spatially variable properties like available phosphorus (R^2 ranging from 0.71 to 0.84). The CNN-Transformer model consistently outperformed other architectures across all soil properties, with the most substantial improvements observed for texture components (sand, silt, clay) and organic matter content.

Impact of Input Features

To assess feature importance, we conducted an ablation study by systematically excluding different feature groups and measuring the resulting performance degradation. Figure 2 illustrates the relative importance of different input features for soil property prediction. Spectral data proved most influential for organic matter prediction (26.8% RMSE increase when excluded), while geographical and topographic features were crucial for texture prediction

(23.5% RMSE increase). Climate variables showed moderate importance across most properties (12.7% average RMSE increase). The CNN-Transformer architecture demonstrated superior feature integration capabilities, maintaining reasonable performance even when certain feature groups were unavailable, suggesting robust feature extraction and cross-modal learning.

Field Validation Results

Field validation confirmed the laboratory performance rankings, though all models showed some performance degradation under real-world conditions. Table 3 presents the field validation results across the 12 test sites. The CNN-Transformer model maintained the highest predictive performance across all site types, with an average field R^2 of 0.836. Performance degradation from laboratory to field conditions was lowest for this model (5.7% reduction in R^2) compared to other architectures (7.9-8.3% reduction), indicating superior generalization capabilities.

Computational Efficiency

Table 4 compares the computational requirements of the different models, an important consideration for practical deployment. While the CNN-Transformer model required the most computational resources, its inference time (18.2 ms/sample) remains acceptable for most practical applications. The performance gains justify the increased computational requirements, especially for high-value agricultural applications where prediction accuracy directly impacts decision-making and profitability.

DISCUSSION

Architectural Advantages of the CNN-Transformer Model

The superior performance of our proposed CNN-Transformer architecture can be attributed to several key design elements

Complementary Feature Processing: The CNN component efficiently extracts local spectral patterns and spatial features, while the transformer component captures long-range dependencies and contextual relationships between different soil attributes.

Multi-modal Integration: The architecture effectively combines spectral data with tabular and geographical information through specialized processing branches and cross-modal attention mechanisms.

Adaptive Feature Weighting: The self-calibrating mechanism dynamically adjusts the importance of different feature types based on their relevance to specific soil properties, enabling robust prediction across diverse soil conditions.

Uncertainty Quantification: The model provides confidence intervals for predictions, allowing users to identify situations where additional soil sampling might be necessary.

These architectural advantages address the limitations of previous soil prediction models, particularly in handling spatial heterogeneity and integrating diverse data sources.

Performance across Different Soil Types

Analysis of prediction errors revealed notable patterns across soil types. The CNN-Transformer model showed consistent performance across diverse soil taxonomic classes, with only minor degradation for Andisols (volcanic soils) and Histosols (organic soils). In contrast, the ANN and RNN models exhibited substantial performance variability across soil types, with particularly poor predictions for extreme soil conditions (very sandy or clayey soils). This consistency can be attributed to the transformer's self-attention mechanism, which effectively captures complex interactions between soil properties without relying on predefined relationships. The CNN component's ability to identify diagnostic spectral features further enhances performance for soils with distinctive mineral compositions.

Practical Applications and Limitations

The developed models have several practical applications

Precision Agriculture: Enabling variable-rate application of fertilizers and amendments based on predicted soil properties.

Digital Soil Mapping: Generating high-resolution soil property maps using limited sampling points combined with remote sensing data.

Carbon Sequestration Monitoring: Tracking changes in soil organic carbon for climate mitigation programs.

Land Suitability Assessment: Evaluating land capability for different agricultural uses based on predicted soil characteristics.

Despite these promising applications, several limitations must be acknowledged

Extreme Soil Conditions: All models showed reduced accuracy for soils with extreme properties (e.g., highly alkaline soils, very high organic matter).

Depth Transferability: Models trained primarily on surface samples (0-30cm) showed performance degradation when applied to deeper soil layers.

Management History: Prediction accuracy was lower for soils with complex management histories or recent disturbances.

Regional Specificity: While our global training dataset improved generalizability, region-specific calibration may be necessary for optimal performance in unique pedological contexts.

FUTURE RESEARCH DIRECTIONS

Based on our findings, we identify several promising research directions

Temporal Dynamics: Incorporating seasonal and long-term temporal dynamics of soil properties through dedicated temporal attention mechanisms.

Multi-scale Spatial Analysis: Developing hierarchical models that simultaneously capture micro, meso, and macro-scale soil spatial patterns.

Transfer Learning: Exploring transfer learning approaches to adapt models to new geographical regions with limited training data.

Physics-informed Neural Networks: Integrating pedological knowledge and physical constraints into model architecture to improve prediction accuracy and interpretability.

Model Explainability: Developing methods to interpret model predictions and identify factors driving soil property variations.

Sensor Fusion: Integrating data from new soil sensing technologies (e.g., gamma radiometrics, portable XRF) to enhance prediction accuracy.

Addressing these research directions will further advance the practical utility of machine learning for soil property prediction across diverse agricultural and environmental applications.

CONCLUSION

This study demonstrated the superior performance of a novel CNN-Transformer hybrid architecture for soil property prediction compared to traditional neural network approaches. Our comprehensive evaluation using multiple performance metrics and extensive field validation confirms the model's effectiveness across diverse soil types and environmental conditions.

Key contributions of this work include

1. Development of a specialized CNN-Transformer architecture optimized for soil data characteristics
2. Comprehensive comparison of neural network approaches across multiple soil properties
3. Robust field validation across diverse agricultural sites
4. Identification of key architectural elements contributing to prediction accuracy
5. Assessment of model performance across different soil types and conditions

The proposed CNN-Transformer model achieved an average prediction accuracy of 91.5% and R^2 of 0.887 under laboratory conditions, with field validation confirming its practical applicability (field R^2 of 0.836). These results represent a significant advancement in machine learning-based soil property prediction, with important implications for precision agriculture, digital soil mapping, and environmental monitoring.

Future work will focus on incorporating temporal dynamics, improving model interpretability, and developing transfer learning approaches to extend model applicability to regions with limited soil data. These advancements will further enhance the utility of machine learning for sustainable soil management and agricultural decision-making.

ABSTRACT

In order to handle the issues linked to standard drug delivery, researchers have started using better and more efficient solutions. In particular, nanoemulsions are—The use of emulsions at such a tiny level is being explored as an effective way to help deliver pharmaceutical ingredients that are used. They can be used for a variety of drugs. The reason for this is that the fins give the fish a wider surface area and better energy transfer, helping them fish more effectively. To make nanoemulsions, you combineby using emulsifiers such as surfactants and co-surfactants, it becomes possible to mix immiscible liquids. The mixture is stable in terms of thermodynamics. The droplets are usually sized between 20 to 200They are just one nanometer in width. Nanoemulsions are different from traditional emulsions because of emulsions are made up of small particles that are evenly spread through a continuous phase. Many industries, including pharmaceuticals, food science, cosmetic formulation, agriculture, and so on—they

are used wherever they are needed. A requirement for dependable methods of transporting goods. The review covers the main concepts that support Formulating nanoemulsions, preparing them, and carrying out analytical work.

Keywords Nanoemulsion, Drug delivery, Types of emulsions, Applications

INTRODUCTION

Emulsions are formed by two parts that do not mix; one part is called the internal (dispersed) phase and there is also an external phase that continues. They start to form by misting tiny drops of one. Both types of molecules exist in equilibrium because of emulsification. Because of this, texture, taste, and other sensory aspects can be determined. Taking advantage of the sense of smell in consumer goods, and also working to boost the efficacy of therapy drugs. Thus, emulsions are commonly used in many industries such as the food industry, pharmaceutical products, as well as cosmetics. Nanoemulsions are a newer type of emulsion that are different from others by their very tiny droplets, usually no more than 500 nanometers in size. These systems add surfactants that help separate droplets instead of allowing them to merge. A protective barrier is formed between the two phases. This way of balancing prices is very important. It does so because the system is always trying to reach the condition of minimum Gibbs free energy. In other words another type of surfactants are proteins and lipids, which have also been proven effective. They are often used well in creating nanoemulsions [2–12].

Unlike traditional or microemulsions, nanoemulsions appear much clearer usually, their appearance is see-through [21]. Their stability is achieved because of two factors the hindrance caused by their structure and repulsion between droplets that is a result of emulsifying agents [1]. The reason for this is their small size with different configurations, they give several advantages that help in drug delivery, including the ability of hydrophobic drugs to dissolve, less chance of side effects, and the possibility to make more changes. These properties are very important in the biomedical field because they help stabilize formulae, keep viscosity to the required level, and ensure better results. Administration is possible using routes called topical, ocular, and intravenous. Moreover, nanoemulsions are excellent ways to produce nanocrystals that are hard to make with other methods. ingredients that can be dissolved in water. Because of their structure, they help the development. for example, encapsulated nanodroplets and biomimetic microparticles.

There are several methods to create nanoemulsions, which are mainly separated into various categories they are sorted into methods that use high energy and those that use less energy. During the last ten years, both approaches have become more popular. Scientists have devoted a lot of effort to studying it [13–15]. Most of the time, high-energy methods need a large amount of mechanical input, usually from 108 to 1010 W kg−1, in these processes. This means that techniques for these machines operate at power levels of only 103 W kg−1 [15]. Widely used low-energy techniques are represented by the phase inversion temperature (PIT) method [16]. The technique known as emulsion inversion point (EIP) [17–19]. In recent years, people have turned to alternative strategies such as evaporative ripening and the breaking of bubbles at the boundary between oil and water [20] have been observed and introduced, so that droplet size and uniformity can be carefully controlled in nanoemulsions
systems.

Advantages of Nanoemulsions

a. Nanoemulsions can be used instead of liposomes as a delivery system.
b. They greatly boost the amount of medicine that can be delivered to the body.
c. Usually, people consider them safe since they are gentle and do not cause irritation.
d. Because nanoemulsions consist of very small droplets, they give a larger surface area compared to normal emulsions and also promoting better and quicker absorption of drugs.

e. Some of these systems can be created in different forms, for example, as sprays, creams, liquids,suspensions, as well as foams.
f. They work very well in dissolving lipophilic (fat-soluble) drugs, which helps them dissolution.
g. Nanoemulsions make it possible to mask the unpleasant tastes found in some medications.
h. Modern techniques allow them to be produced with less energy.

Disadvantages of Nanoemulsions

1. The stability of nanoscale droplets is maintained by using plenty of surfactants and co-surfactants. They are regularly used to prevent businesses from joining or increasing in power.
2. Sometimes substances that need solubilizing are too complicated for them. Very high temperatures are required to melt them.
3. In pharmaceutical uses, any surfactant chosen should be safe for the body and non-toxic so that patients are safe.
4. Picture shows that both pH and temperature have a strong effect on nanoemulsions stability, and these conditions may change in the body after the medicine is given [22].

Type of Emulsions

There are mainly two kinds of emulsions single and double.
Emulsions are formed depending on the number of phases present in the system.

One Phase Emulsions

Frequently, single-step techniques are used for making water-in-oil (W/O) or oil-in-water (O/W) kinds of emulsions. To put it simply, emulsions are made up of two liquids that do not blend together. Parts known as hydrophilic and hydrophobic that are found when mixed with an emulsifying agent, they become one. One phase is spread evenly throughout the other (refer Fig. 1). In particular, W/O emulsions consist of small water droplets suspended in the fatty part of the system. Oil emulsions have oil as the main continuous phase, but in O/W emulsions the oil is dispersed among water droplets of aqueous medium.

Double Emulsions

Double emulsions are complex systems made up of alternating layers of aqueous and oily phases. Their formation generally involves a two-stage process. In the first step, a primary emulsion—such as a water-in-oil (W/O) system—is created using a surfactant with hydrophobic properties to stabilize the phase boundary. This initial emulsion is then introduced into an outer aqueous phase with the aid of a hydrophilic surfactant, resulting in the formation of a secondary emulsion. For example, in oil-in-water-in-oil (O/W/O) emulsions, an oil-in-water (O/W) emulsion is first generated and later dispersed into a surrounding oil medium. To ensure that the internal droplets remain intact during the second emulsification stage, the mechanical shear applied during the creation of the primary emulsion is deliberately minimized [23].

Components of Nanoemulsion

Most nanoemulsions consist of three important parts an oil phase, an aqueous phase, and a surfactant. The main components are the water phase, as well as emulsifying agents. There are many different oils used in their preparation. Collectively, corn oil, linseed oil, mineral oil, olive oil, peanut oil, castor oil, and coconut oil are all parts of formulation including oils such as evening primrose and similar oils. The method starts by mixing the oil and water to form the first emulsion. Still, the blend at first is not stable and gradually separates into layers because of the droplet. Use of an emulsifier—also known as an emulgent—is one way to deal with this instability of the system. They keep different ingredients from separating and are very important in the process, improving how well the nanoemulsion remains stable. Many types of emulsifiers exist for use in food,among the things used, there are hydrophilic colloids like gum acacia and surfactants called Spans and Tweens. In addition, finely dispersed solids like bentonite and Veegum are also included.

Methods of Preparation

Emulsions are formed when two immiscible liquids are subjected to mechanical forces that break one phase into tiny droplets dispersed throughout the other. There are mainly two strategies used to generate the required shear stress the first employs specialized equipment to deliver external mechanical energy—referred to as the high-energy method—while the second is based on manipulating the physicochemical properties of the phases and surfactants in response to thermal or chemical triggers—known as the low-energy approach. Nanoemulsions typically contain droplets ranging from approximately 100 to 600 nanometers in size and can be produced using a variety of techniques. Although many of these methods involve substantial energy consumption, the essential goal of any preparation technique is not only to achieve nanoscale droplet formation but also to ensure their long-term physical stability.

The two most widely used approaches for nanoemulsion formulation are
(a) High-energy emulsification
(b) Low-energy emulsification

High-energy Emulsification Methods

High energy emulsification includes ways such as rapid stirring and ultrasonic technique.
high-pressure homogenization, microfluidization, and emulsification done using membranes are key methods. These techniques use strong mechanical forces to break down the droplets and
form emulsions that are stable at a nano scale.

Low energy Emulsification Methods

Some low-energy techniques are phase inversion temperature (PIT) and emulsion inversion point and emulsions can be formed naturally without any special equipment. The methods rely on changing formulation factors for example, taking advantage of the natural phase change process to make nanoemulsions, without stronger tools and mechanical forces. Unlike higher-energy methods, low-energy techniques are usually use less energy and involve milder methods during processing.

High-energy Emulsification Methods

Usually, the process has two main steps. At the beginning, you need to put oil, water, and surfactant in a container. Put the mixture in a mixer with a blade for a certain amount of time to get a coarse oil-in-water emulsion. water (O/W) macroemulsion is the term used here. Next, the rough emulsion is improved into a nanoemulsion to reach the correct size. At this stage, you should use homogenization equipment, such as a high-pressure the pump—in this case—helps by pushing the macroemulsion through a very small opening. The strong shear and extensional forces made during this passage help lower the size of the droplets by a lot. This particular treatment is mostly performed under high pressure, repetitive steps are taken until the right droplet size is obtained [25,27]. Droplet disruption happens during ultrasonication due to the strong turbulent forces produced. High-frequency sound waves are produced inside an ultrasonic generator. It is much the same as high-pressure until a steady and identical droplet size is achieved.

Ultrasonic Emulsification

The process of ultrasonic emulsification is very effective at making droplets smaller. It is possible because it uses energy that is produced by sonotrodes, sometimes called ultrasonic probes. These instrumentshave a piezoelectric quartz crystal that vibrates fast whenever an alternating electrical Current, this is happening, so the earth keeps expanding and contracting. If the probe's point is placed in a liquid through this, the rotor creates intense shaking and also produces tiny bubbles filled with air and water and it collapses and disappears inside the liquid. Such an action creates the forces that break droplets apart this means that the sizes are much smaller, allowing ultrasonic waves to directly produce emulsions. This technique is utilized in the lab when precise droplets, often as small as 0. 2 mm are necessary.

High pressure Homogenization

Through this process, the separation of water from oil is strongly broken. Oil phases help to split up the large oil droplets into many smaller ones [28]. This method plays an important part in making nanoemulsions with tiny particles. Using a high-pressure or piston homogenizer, it is feasible to produce emulsions with droplet sizes as small as approximately 1 nm. Preparing a coarse emulsion with a typical mixer is the first step of the process which is followed by feeding it into the homogenization system. The liquid passes through a chamber that can be adjusted the area between the valve seat and the valve mechanism helps to control fluid precisely dynamics. The high-speed fluid entering this area lets out a lot of energy. Creating strong vortices help in lowering the size of droplets.

With the liquid moving up through the valve, the pressure drop results in more and more droplets to break into smaller pieces. Cavitation is the name given to this effect that makes the emulsification process work more efficiently. This is due to the significant warmth that exists during homogenization, the mixer combines raw materials and pre-formed emulsions. Usually, water is cooled to about 40°C prior to being added to the system. A diagram made to illustrate electrical circuits. Figure 4 [29] displays how the high-pressure homogenization setup is arranged.

Micro Fluidization

The microfluidization technique mainly employs a specialized device called a Microfluidizer. During the process, the formulation is subjected to high pressure and passed through an interaction chamber, resulting in the generation of extremely fine particles within the submicron range. To achieve a consistent nanoemulsion with the targeted droplet size, the procedure is typically repeated several times.

Low Energy Emulsification Methods

Low-energy methods are very different from high-energy ways. In this method a water-in-oil (W/O) macroemulsion is typically formed first, and is then turned into oil-in-water (O/W) nanoemulsions can be achieved by changing the composition or the temperature. On the Alternative manner , high-energy procedures usually start by forming an O/W emulsion as the first phase, this is then further improved by being processed mechanically.

Phase inversion temperature

The trick is to cause the emulsion to change phase by increasing its temperature. temperature. It uses the energy that is set free during the different phases of the substance. They develop during emulsification, which makes it possible to create a finely dispersed system [30]. The formula can be changed while the process is kept the same for phase inversion. You can control reaction temperature or regulate it as the mixture remains constant. The success of using the Phase Inversion Temperature (PIT) method has been proved mostly depending on the temperature-based solubility of polyoxyethylene-type surfactants [31]. As the temperature rises, these surfactants lose water molecules—a process known as dehydration—enhancing their lipophilic (oil-attracting) properties. At the same time, when levels are low the surfactant layer takes a curved shape that favors formation of a sphere leads to the creation of a micelle structure that contains oil [32].

Spontaneous Emulsification

The method is praised for using little energy compared to other techniques. Nanoemulsion preparation is especially beneficial because it does not depend on advanced methos. Nanoemulsions are created even without special equipment or high levels of heat. conditions. It is typical to form oil-in-water nanoemulsions by just mixing water. by gently mixing the oil phase that has a surfactant in it. However, the success of this method depends on several key factors, such as the phase transition zone, the type and concentration of surfactant used, and the interfacial and bulk viscosity, as well as the surface tension between phases. A notable drawback of this approach is the limited capacity to incorporate high amounts of oil, along with the need for certain solvents, which can constrain its broader application [33].

Factors Influencing the Development of Nanoemulsions

i. Selecting an appropriate surfactant plays a crucial role in reducing interfacial tension, which is essential for the successful formation of nanoemulsions.
ii. A sufficient concentration of surfactant is required to effectively stabilize the small droplets during the development of nanoemulsions.
iii. The surfactant should be versatile enough to support the formulation process and aid in the generation of stable nanoemulsions.

Characterization of Nanoemulsions

A nanoemulsion is considered sufficiently stable if it retains consistency in its physical attributes—such as appearance, color, odor, and texture—and remains free from internal phase separation, creaming, and microbial contamination. Instability in emulsions can generally be classified into the following categories

- Flocculation and Creaming
- Cracking
- Miscellaneous Instability
- Phase Inversion

Flocculation and creaming

When globules in an emulsion aggregate to form larger clusters known as floccules, they tend to move more readily—either rising or settling—through the emulsion compared to individual globules. This phenomenon is referred to as flocculation . In the process of creaming , these aggregated globules rise or sink through the emulsion, eventually forming a concentrated layer. Thus, creaming typically occurs as a result of prior flocculation.

Cracking

Cracking in emulsions occurs when the dispersed phase begins to separate into distinct layers. Once an emulsion has cracked, the process is typically irreversible. However, in the case of creamed emulsions , where separation is less severe, it may be possible to restore uniformity through gentle shaking or stirring. Cracking is a clear indicator of poor emulsion stability and can be influenced by several factors,
Including

- The addition of an incompatible emulsifying agent (emulgent),
- Degradation or breakdown of the emulsifier due to chemical or environmental factors,
- Temperature fluctuations , which can disrupt the balance between phases,
- Microbial contamination , which may degrade components of the emulsion system.

Proper formulation and storage conditions are essential to minimize the risk of cracking and ensure long-term stability. Emulsions are prone to degradation when stored at extreme temperatures—either high or low or when exposed to light. To maintain their stability and prolong shelf life, it is essential to store emulsions at a moderate, controlled temperature and to package them in colored, airtight (hermetically sealed) containers that protect against environmental factors.

Phase inversion

When an emulsion goes through phase inversion, it alters between two different forms.
for example, when an oil-in-water emulsion (O/W) is converted to a water-in-oil emulsion (W/O),the reverse. Various things can cause this change in structural behavior, such as changes in thechanging the phase volume ratio, using electrolytes, or altering the temperature. These influencesmodify how the two phases are in contact and destabilize their equilibrium. Which leads to a reversal of the emulsion type.

Assessment Parameters of Nanoemulsion

Droplet Size Determination

Scientists can measure the size of droplets in nanoemulsions with the help of diffusion. Using light scattering techniques, for example, those offered by a particle size analyzer or the LS 230 instrument. Estimating the size of droplets can also be done using correlations. spectroscopy measures the changes in scattered light that happen because of Brownian movement of particles. Moreover, TEM is another method that can be used for this purpose. alternative way to precisely assess the size of droplets in nanoemulsions.

Viscosity Measurement

A Brookfield rotary viscometer is normally used to measure the viscosity of a nanoemulsion. Experiments are done at different shear rates and temperature levels to check on the system. Changes in the way it moves depending on the environment.

Dilution Test

The purpose of this test is to see how a nanoemulsion can maintain stability when a larger amount of the continuous phase is present in the solution. The next step is to dilute the nanoemulsion using water or oil. This means a W/O nanoemulsion can be diluted even more. In an oil-in-water (O/W) system, adding more water to the mix is possible, unlike an oil-in-oil (O/O) system. without destabilizing.

Drug Content Analysis

A known amount of the nanoemulsion is obtained by dissolving it in the right solvent. After getting the solution, it is analyzed by a spectrophotometer or by High-Performance. Using Liquid Chromatography, the results are then compared to a standard medicine to find out the actual substances in the drug.

Polydispersity

Polydispersity shows the different droplet sizes that exist in a nanoemulsion. Having a polydispersity index of 1 means that there is less uniformity in the size of the droplets. Usually, it is determined through figuring out the ratio between the standard deviation and the mean droplet size. You may alter this parameter by it is measured using a spectrophotometer or similar equipment that scatters light.

Dye Test

Putting a water-soluble dye into an O/W nanoemulsion results in a nanoemulsion with even color circulation within every part of the system. Conversely, when this dye is used in a water-in-The oil (W/O) nanoemulsion is soluble in the internal aqueous phase, so it leads to an uneven color appearance. It is easy to observe this difference when using a microscope.

Refractive Index Measurement

The Abbe refractometer is used to find the refractive index of a nanoemulsion.
It measures the way light bends when it goes through the sample.

pH Measurement

The pH of the nanoemulsion is measured using a calibrated pH meter to assess its acidity or alkalinity.

Zeta Potential Analysis

The zeta potential of a nanoemulsion is measured using a Zeta PALS instrument. This device evaluates the electrical charge on the surface of the droplets, which plays a key role in determining the system's stability.

Fluorescence Test

When UV light shines on many oils, they will glow visibly. When nanotechnology creates a nanoemulsion. if seen through a fluorescence microscope, the entire area glows evenly. It points to an emulsion made with oil in water. Alternatively, if the fluorescence looks uneven, In case it is irregular, the oil-in-water (O/W) nanoemulsion is most likely the structure formed.

Conductivity Measurement

Nanoemulsion electrical conductivity can be measured with a device called a conductometer. Part of the technique is putting a sample of the emulsion onto both glass plates. The circuit has electrodes that are linked to a battery and a light indicator. When we use oil-in-water (O/W)As the continuous phase is water, which carries electricity, the light changes coloron. On the other hand, a W/O nanoemulsion uses non-conductive oil for its outer phase, so the light stays off. This easy procedure makes it possible to distinguish the two types of emulsions. types that are grouped by how conductive they are.

Filter Paper Test

Here, the test is carried out by studying how the emulsion reacts on filter paper. Only a little of the emulsion is put on the paper's surface. The case of oil and water not mixing is an example of oil-in-water emulsion. Since (O/W) nanoemulsion is formed with the continuous aqueous phase, it distributes rapidly. On the other hand,W/O nanoemulsion moves slowly and is not easily able to diffuse. solvent used outside the membrane that is not water.

Applications of Nanoemulsions

Nanoemulsions show unique features, for example, they are made of extremely small droplets and are highly stable. A translucent or semi-transparent look, combined with the ability to change their rheology. This is why they are important in food, cosmetics, pharmaceuticals, and drug delivery industries. In addition, nanoemulsions are a perfect base for creating innovative materials that are changed to exhibit certain functions. These are some of the main accomplishments of evolution. It plays a role in many types of fields

Nanoemulsions in Drug Delivery

Nanoemulsions are important in the process of delivering drugs through the skin. Drugs can be given by eye drops, injections, as nasal sprays, or by mouth. They use these applications to gain benefits. Since nanoemulsions are lipophilic, they are able to effectively dissolve substances that are not water. Furthermore, their ability to be charged and change their Rheology is important too. To produce water-based mixtures that are easy to give to patients making it both more useful and easier to use.

Topical drug delivery

Although the skin defends our bodies from hazards outside, it often causes us big problems.
the proper and efficient transport of drugs to their targets. This problem is solved using nanoemulsion technology. Topical formulations are now commonly including them. They have several features that make them unique. O/W nanoemulsions have the benefit that the dispersed oil particles help increase the solubility lipophilic drugs are used to benefit the skin, while the aqueous solution keeps the environment gentle. Since this stage involves water, biopolymers such as alginate can be used. changes to the way the formulation feels, appears, and flows. In the last few years,Interest in using nanoemulsions for bettering the efficiency of products is steadily increasing. Sending drugs into the body through the skin is a form of delivery [34–51].

Parenteral Delivery

Doctors often choose nanoemulsions for intravenous administration because their size is below a micrometer with a smallest scale of one micrometer. They are often given by injection to meet the needs of different functions such as supplying lipids, carbohydrates, and vitamins. Nanoemulsions provide better results than traditional macroemulsions do.

Most parenteral drugs are formulated as injections because their droplets are much smaller. The size of the particles has been reduced that boosts the stability of the molecule and allows it to stay in the blood for a longer period. Both oil-in- Nanoemulsions with water (O/W) and water-in-oil (W/O) arrangements are excellent for parenteral purposes.

Oral Delivery

Nanoemulsions provide several advantages over traditional oral formulations, particularly in terms of improved clinical effectiveness, enhanced drug absorption, and reduced toxicity. Because of these favorable characteristics, they are increasingly used in the delivery of a widerange of medications, including steroids, hormones, diuretics, and antibiotics. Additionally, nanoemulsion-based systems show great promise for delivering peptide- and protein-based therapeutics, which are known for their strong biological activity and specificity. For example, when primaquine—an antimalarial drug—was formulated into an oral lipid nanoemulsion, it successfully treated Plasmodium berghei infection in mice. The nanoemulsion demonstrated notable antimalarial efficacy at a dose that was 25% lower than the conventional dosage. This improvement was linked to the increased oral bioavailability of primaquine through hepatic uptake, with drug concentrations rising by at least 45% compared to the pure compound[52].

Ocular Delivery

Doctors most frequently use topical administration to apply eye drops for ocular conditions.

There has been a rise in attention on nanoemulsions for research in ophthalmology due to potential to help poorly water-soluble drugs mix well with water, improve their absorption, and have the ability to release medicine over a long period [53].

In Cosmetics

Their special qualities make nanoemulsions highly useful in the cosmetic industry applications. Because of the fact that these droplets are low viscous, clear, small, and large the shape of interfacial surfaces make it possible for active ingredients to get to the skin quickly. Compared to traditional macroemulsions, nanoemulsions demonstrate superior stability and are less prone to common instability issues such as creaming, sedimentation, flocculation, or droplet coalescence. Furthermore, the use of high-energy methods during preparation can reduce the need for potentially irritating surfactants, thereby improving both product safety and skin tolerance. Oil-in-water miniemulsions are commonly made with the help of nanogel technology.

These systems give some advantages, like less transepidermal water loss. Loss of water, better protection of the skin, and better absorption of beneficial compounds. As a result, nanoemulsion-based products may be useful in the fight against aging. There are products, moisturizers, and formulations for sun protection in the market.

Transdermal

In a study conducted on rats with carrageenan-induced paw edema, the anti-inflammatory efficacy of an optimized nanoemulsion formulation was evaluated against a commercially available gel. Indomethacin, a powerful nonsteroidal anti-inflammatory drug (NSAID), showed strong potential for transdermal delivery when formulated as a nanoemulsion, as demonstrated by a high percentage inhibition value. The drug was also applied via nanoemulsion with 2% celecoxib and a 10% phase that uses Sefsol 218 or Triacetin, and a 50% mixture of Tween 80 and Transcutol-P solvent and a 40% water solution were used for the purpose. Conventional celecoxib gel works less effectively than the new formula (43. 7%). among the formulations, the gel based on nanoemulsion showed the most effective outcome There was an increase in anti-inflammatory effects, with 81. 2% inhibition after 24 hours. Additionally, both in vitro and in vivo studies revealed that aceclofenac administered through nanoemulsion resulted in enhanced anti-inflammatory effects, with 82. 2% inhibition—surpassing both the nanoemulsion gel (71. 4%) and the standard gel formulation. These results underscore the promising role of nanoemulsions in enhancing the transdermal delivery of NSAIDs, leading to improved therapeutic performance.

Nanoemulsions in Gene Delivery

Emulsions are now seen as a good alternative to liposomes when transferring genes. Work done on delivering genes by emulsions—mainly without using the lungs—has Shown that the complex formed by the emulsion and DNA is more stable than the usual. Stable nanoemulsions, in fact, work more efficiently than normal emulsions. At this point, viruses are more reliable than liposomes when moving genetic material. Various parameters, such as incubation temperature, duration of complexation, and the phase (aqueous or oil) in which stearylamine is incorporated, were evaluated for their influence on gene delivery performance. The characterization process involved the use of dynamic light scattering (DLS) to assess particle properties. Researchers observed that after a period of complexation, DNA was compacted at its best.

It was done for 120 minutes at 4 ± 1 °C , with the cationic lipid added. the part of the mixture that contains water. The zeta potential of the lipoplexes was lower when compared to standard nanoemulsions did not show any important changes in granulometry. Furthermore, these studies confirmed that lipoplexes —formed by combining lipids and nucleic acids—are effective and suitable carriers for gene delivery applications[54].

Nanoemulsions in Pulmonary Drug Delivery

The lungs are a good choice for delivering drugs since they have several important advantages. These use inhalation aerosols because they avoid causing harm in the liver, and the option to deliver treatment directly to the respiratory system, and the fact thata large surface where local treatment happens and the drug can also be carried through the body. The use of nanocarriers as colloidal delivery systems gives many advantages to pulmonary therapy. They can ensure that the drug is spread evenly to all parts of the alveolar. create different regions, allow better absorption of drugs, and control when they are released. These features let patients take their medication less often, make it easier for them to remember, and reduce the odds ofside effects. Besides, nanocarriers promote the ability of cells to take in therapeutic agents. as a result, the overall success of the treatment can be increased.

Current Perspectives and Future Prospects

Over the years, various research projects have been done to find out the advantages of putting lipophilic and functional compounds within nanoemulsions. Study done in laboratories is proved that nanoemulsions can substantially increase the amount of bioactive absorbed by the body. Substances are protected by covering them with a shell.

However, only a limited number of studies have explored the actual health benefits, labeling aspects, and public perception associated with consuming foods containing nanoemulsions. Research has also been conducted to determine whether high-energy or low-energy methods are more suitable for nanoemulsion preparation, aiming to optimize formulation parameters and ingredient selection. Despite their promising applications in food packaging and fortification, the development and use of nanoemulsions require significant energy input and investment in specialized equipment. Unfortunately, there has been minimal research into reducing the production costs associated with these systems. Moreover, the potential risks of incorporating nanoemulsions into food products remain largely unknown. The toxicological effects and biological fate of nanoparticles after ingestion have notyet been fully characterized. The application of nanoemulsions in the food industry—particularly for delivering bioactive compounds and functional ingredients—holds great promise. Emulsion-based delivery systems and edible nanoemulsion coatings can enhance food functionality, improve product quality, and extend shelf life. To support scalability and commercialization, it is essential to maximize the bioactivity of encapsulated components.

Moving forward, more emphasis should be placed on understanding the biological impacts and potential risks linked to nanoemulsion-based delivery systems in food products and packaging. This will be crucial in ensuring consumer safety and promoting regulatory acceptance.

CONCLUSION

At present, the advantages of nanoemulsion systems significantly outweigh their limitations. Nanoemulsions possess unique physicochemical and functional properties that enable their widespread use across diverse industries such as food, polymer manufacturing, healthcare, and cosmetics. Beyond the food sector, nanoemulsions also show great promise in various other applications. They have recently been utilized in the treatment of inflammatory conditions and periodontitis, as well as in agrochemicals, pharmaceuticals, cosmetics, and personal care products. These systems are also effective as texturizing agents, creams, formulations for non-steroidal anti-inflammatory drugs (NSAIDs), and delivery vehicles for drugs and vaccines. Additionally, they are being explored for cosmeceutical applications and alcohol-free perfume formulations. The enhanced surface area, increased entropy, and reduced adverse effects associated with nanoemulsions contribute to their superior performance compared to conventional emulsion systems. The growing number of patented nanoemulsion-based products intended for commercial applications underscores the multiple benefits offered by this technology. Overall, the advantages of nanoemulsions far surpass their drawbacks, and they have demonstrated promising results across numerous fields, paving the way for further research and innovation.

ABSTRACT

Early childhood obesity is an increasingly creating a serious public health issue in INDIA. It is observed by the statistics that by 2040 there is an increase in the obesity risk in younger population in urban and semiurban regions where the lifestyles and their daily routines are affected in major. The global studies have focused extensively on obesity prediction and prevention but there exists a gap in region specific models tailored to the Indian demographic, socio-economic and cultural context. The study aims to bridge the ga by developing an Artificial Neural network (ANN) model specifically for region specific children aged 12 to 15 years in the Tumkur city. The model integrates the conventional parameters as well as the physical fitness metrics. The study also proposes the development of a mobile application that enables real time risk monitoring and parental involvement through personalised alerts progress tracking and behavioural based recommendations. The study is analysed on the primary data collections from the different schools in Tumkur city representing novel approach in preventing the obesity.

Keywords: Childhood Obesity, Artificial Neural Networks, parent centric interventions, Mobile application, Deep learning.

INTRODUCTION

Obesity is a severe problem recognised by the government of India under which Hon. PM Modi, the prime minter of India has recommended the prevention of obesity in the younger generation according to the statistics, it is said that by 2040 there is an increase in the obesity in younger population.

The literature review of the ten different journals had provided the overview on the prediction and prevention of obesity in different perspectives. Machine and deep learning models have demonstrated high accuracy in predicting child obesity. The significant gap remains due to the lack of personalized and regional models. This creates a clear need for research into region specific fitness inclusive AI tools proposed in Tumkur model that integrate multimodal data like physical activity and local dietary habits. An evolution of gradient boosting, random forest and Logistic regression models demonstrated that integrated clinical EHR data with social environmental variables improve child obesity prediction. This multi approach provided a more Holistic assessment then using clinical data alone. The study was limited by a lack of real time data integration and challenges in generalizing its finding highlighting the potential value of incorporating dynamic individual matrix like physical fitness indicators to create more and adaptable model. An Exploration into early child obesity value of structure health records from the first two years of life and reinforced the importance of early intervention. This research did not incorporate non clinical data presenting an opportunity to enhance these early life models by integrating fitness and behaviour Matrix collected via modern technology. An investigation into the use of RNN and LSTM models successfully predicted child obesity from time series electronic health records the work emphasize the critical role of longitudinal data in making reliable predictions and offered insights into a optical amount of information required.

This study focus only on historical EHR data. Across sectional study in Udupi Karnataka focused on the prevalence and determinants of obesity among Indian school children examining key social economic dietary and urban rural influences the finding confirm that the local lifestyle and economic factors are the significant predictors making it a valuable regional parallel for a Tumkur based project study on move it system detailed the design of variable device enable AI for both predicting childhood obesity and providing customised fitness interventions app. This work closely Alliance with plans for a mobile application that combines AI with parent focus feedback by using real time physiological and activity data. Deep Health NET achieved high accuracy in predicting by combining variables like BMI waste circumference calorie can take and physical activity will stop the models related the strength of using multiple lifetime and biometric indicators as a key performance benchmark. The study estimated from BMI from facial images using convolutional neural networks achieving a low mean absolute error. This showcased how innovative image based deep learning can supplemental health data inspiring alternative approaches to non-invasive obesity prediction. A Logistic regression analysis demonstrated that early life indicators specifically BMI birth weight and infant weight gain can effectively predict future obesity. The study focus the necessity of proactive measures before H2 and validity the predictive strength of all on anthropometric data. A proposed design for obesity management using IoT and mobile apps outline the system with real time monitoring personalized notification and give me fight feedback the system architecture highlighted critical consideration including data privacy user engagement and continuous tracking providing and essential blueprint for an application feature as a conceptual Framework it's primary gap is a lack of implementation and testing.

Childhood obesity has rapidly escalated into a major Public Health challenge worldwide with WHO identify it has one of the most serious Global Health issues of the 21st century overweight and obese children are at significantly higher risk of developing non communicable diseases such as type to diabetics, cardiovascular, conditions muscular skeletal disorders at an Earlier age. They are also more likely to experience psychological consequences such as low self-esteem, depression and socio isolation. In India the problem is particularly concerning due to the dual burden of small nutrition where under nutrition coexist with the rising incidence of obesity- especially among children in urban areas.

There is a clear cap in the development of localised, data driven models that incorporate real time, actionable inputs from both children and their care givers. moreover, the role of parents in shaping child health behaviours cannot be overstated. Existing studies often neglect importance of parental engagement intervention models which limits the effectiveness of health programs. An integrated approach that combines School based health data with parent focus tools and predictive system holds great promise in improving early identification and long-term management of obesity risk among children. This study seeks to address these gaps by developing a novel, interdisciplinary model that mergers localized data collection, simple physical fitness testing, artificial intelligence and real time mobile

health applications. Focusing specifically on Indian school children aged 12 to 15 years in Tumkur urban schools, research aim to produce a culturally Relevant, scalable and interactive system for early obesity prediction and intervention setting a foundation for both academic advancement and public health policy innovations in India.

Objectives

1. To develop a region specific ANN model that predicts the childhood obesity risk using physiological, behavioural and environmental parameters among School children aged 12 – 15 years.
2. To evaluate and incorporate novel, functional physical fitness metrics (such as jumping points and heart rate variability) alongside traditional anthropometric indicators like BMI and weight.
3. To design and implement a parent-centric mobile application that integrates with the AI model to provide real-time risk assessments, personalized lifestyle recommendations, and engagement tools for early intervention.
4. To assess the effectiveness of integrating AI-based prediction with parental involvement in initiating timely lifestyle changes that reduce childhood obesity risk and promote overall health and wellness.

RESEARCH METHODOLOGY

Research Design: A mixed-method, cross-sectional study integrating quantitative data collection from school-aged children and qualitative engagement with parents through a mobile app interface. The model will be trained and validated using supervised learning approaches within an artificial neural network framework.

Population & Sampling: The study will focus on children aged 12 to 15 years enrolled in private and government schools across the Tumkur urban area. A stratified random sampling technique will be employed to ensure representation across gender, age, and school types. The proposed sample size is 500 participants, which offers a statistically significant base for training and testing the neural network model.

Data Collection:
Primary Data:
Structured Questionnaires for Parents: Designed to capture information on dietary patterns, screen time, sleep duration, physical activity outside school, family history of obesity or diabetes, and psychological well-being.
On-Site Physical Assessments: Conducted in schools by trained staff to record height, weight, BMI, resting heart rate, and performance in physical fitness tests such as shuttle runs and vertical jumps.
Teacher/School Observation Logs (optional): To track in-school activity levels, participation in physical education, and general classroom behavior related to health.

Technology Tools
Digital Measurement Tools: Pulse oximeters, digital scales, stadiometers, and fitness assessment kits.
Mobile Application: Custom-built, cross-platform compatible app to collect, store, and analyze user data. Includes interfaces for parental feedback, lifestyle tracking, and personalized intervention tips.

Secondary Data
Although the focus is primarily on primary data, secondary data may be used to enhance model accuracy and for comparative analysis. Sources may include:
Published Literature: Existing research studies on childhood obesity and related risk factors.
Public Health Databases: National or regional data sets on child health indicators.
School Records: Historical academic and health performance (if permitted and available).

Ethical Considerations
Approval will be obtained from the appropriate educational authorities.

Informed consent will be taken from parents and assent from children.
Data confidentiality, anonymity, and digital security will be maintained throughout the research.

LITERATURE REVIEW

Siddiqui *et al.* (2021): In their comprehensive *IEEE Access* survey, Siddiqui et al. reviewed over 50 machine and deep learning models used for predicting childhood and adolescent obesity. They found models like ANN, SVM, and CNN achieving accuracies up to 96%. However, they noted a lack of personalized, regional models and called for integration of multimodal data such as physical activity, dietary habits, and psychosocial factors. This study validates the need for region-specific, fitness-inclusive AI tools like the proposed Tumkur model. Chatterjee *et al.* (2021): Published in *Advances in Communication and Computational Technology*, this study compared SVM, KNN, and ANN algorithms for obesity prediction in toddlers. ANN outperformed other models due to its ability to learn complex nonlinear relationships among features such as weight, age, and BMI. The findings support the suitability of ANN for predicting obesity risk, especially when expanded with physical fitness metrics, as proposed in the current study.

Dugan *et al*. (2015): This study explored early obesity prediction in children using six machine learning techniques, including decision trees, Naive Bayes, and Random Forests. The data was derived from clinical records of infants under two years old, achieving a prediction accuracy of ~85%. It highlighted the importance of early intervention and the predictive value of structured health records—insights critical to integrating early health and fitness data in your ANN model. Cheng *et al.* (2022): Published in *BioMedInformatics*, Cheng and colleagues investigated the application of RNN and LSTM to predict childhood obesity from EHRs. They emphasized the role of time-series health data and discussed the optimal amount of information required to make reliable predictions. This study is crucial for informing how much and what type of early-life data should be integrated into your ANN and mobile app for real-time tracking.

Gautam & Jeong (2019): This cross-sectional study in Udupi, Karnataka focused on the prevalence and determinants of obesity among Indian school children. It examined socio-economic, dietary, and urban–rural influences, making it a valuable regional parallel to your Tumkur-based project. The finding focused on the need for Indian specific obesity predictions models that relate to local lifestyle and economic variations. Garg & Pundir (2021): In this study the author designed a wearable device enabled AI system using XG boost and Random Forest fort predicting obesity in early children. The system provided customised fitness interventions through the apps using physical and activity data.

Jeong et al. (2023): Jeong and team developed *DeepHealthNet*, a deep learning model using variables like BMI, waist circumference, caloric intake, and physical activity to predict adolescent obesity. Achieving over 93% accuracy for boys and 91% for girls, it demonstrated the strength of combining multiple lifestyle and biometric indicators. This serves as a performance benchmark for your ANN model using novel physical fitness parameters. Siddiqui et al. (2020): In this study the author estimated BMI using facial images via CNN using unconventional inputs in achieving the mean absolute error of 1.04 showcasing image based deep learning through traditional health data. Logistic Regression Study (2019): This study demonstrated how the parameters can predict the future obesity with an AUC of 0.77. It emphasized the need for proactive measure before age 2 and validated the strength of anthropometrics data. Alturki *et al.* (2021): This study focused on the IOT and mobile apps for obesity management by designing real time monitoring gamified feedback and personalised notification. This provides an blueprint for proposed app features.

Literature Review Summary Table 1
Connectivity Between Research Objectives and Literature Review Gaps Table 2

Neural network Model integrating with the parameter

BMI-A foundational Metric

Body mass index (BMI) is basic metric which is used to indicate the obesity and for clinical screening. It is an anthropometric measure provides to asses the body changes across the age groups and gender.

$$\text{BMI} = \frac{\text{weight (kg)}}{[\text{height (m)}]^2}$$

CDC growth chart and BMI percentile interpretation

For children aged 12–15 years, BMI values must be interpreted using age- and sex-specific percentile charts. These percentiles are derived from large-scale population studies and recommended by the Centers for Disease Control and Prevention (CDC).

Neural Network Integration: Using BMI for Obesity Risk Prediction

Development of the ANN model combining with other physiological indicators like height and weight to learn the complex patterns.

Neural Network Model Overview

Activation Functions Used in the Neural Network

To improve the learning ability of the neural network used in this study for childhood obesity prediction, two common activation functions are used: ReLU (Rectified Linear Unit) and Sigmoid.

ReLU (Rectified Linear Unit)

Formula:

ReLU(x)=max(0,x)

How it works: If the value is positive, it remains unchanged; if it's negative, it becomes zero.

Where used: In the hidden layers of the neural network.

Why used:

Makes learning faster

Helps the model detect patterns better

Reduces computation time

Sigmoid Function

Formula:

$$\text{Sigmoid}(x) = \frac{1}{1+e^{-x}}$$

x is the input value to the sigmoid function. In a neural network, this is the weighted sum of inputs (like BMI, weight, height) passed to a neuron. i.e

x=(w1*BMI)+(w2*Weight)+(w3*Height)+b

where:w1,w2,w3 are weights and b is the bias term

e is Euler's number:e≈2.718

It's a constant used in exponential functions and naturally appears in growth models, decay models, and machine learning functions like sigmoid.

In this formula, e^{-x} represents exponential decay, which helps shape the S-curve of the sigmoid function.

How it works: Converts any input into a value between 0 and 1.
Where used: In the output layer of the network.
Why used:
Gives a probability value
Helps us interpret the result (e.g., 0.85 means 85% chance of obesity risk)

This setup ensures that the model is both efficient and accurate in predicting childhood obesity based on BMI, weight, and height.

The sigmoid curve with **BMI percentile ranges and interpretations** clearly marked:
Underweight (< 5th percentile) → Low probability (~0.01), indicates **nutritional risk**
Normal weight (5th–<85th percentile) → Moderate probability (~0.27), indicates a **healthy range**
Overweight/Pre-obese (85th–<95th percentile) → High probability (~0.82), signals **early obesity risk**
Obese (≥ 95th percentile) → Very high probability (~0.98), indicates **high risk of chronic conditions**

Advantages of This Integration
Personalized Risk Score: Unlike static charts, ANN can predict risk even when BMI is within the "normal" range, based on combinations of features.
Adaptability: The model can be retrained on region-specific data (e.g., Tumkur urban population) to capture local health trends.
Mobile Application Interface: Real-time BMI calculation and ANN-based risk prediction can be embedded into a parent-centric mobile app, allowing alerts, lifestyle tips, and progress tracking.
By integrating BMI computation and CDC percentile standards into a neural network-based architecture, this research not only adheres to clinical best practices but also enhances predictive accuracy through AI. This hybrid approach supports early detection, personalized risk assessment, and real-time intervention for childhood obesity.

Novelty of the Study: This study introduces a unique and practical approach to predicting early child obesity by combining artificial intelligence, mobile health Technology and parent focus interventions. unlike previous studies that relay mainly on BMI and diet this model is specifically designed for school children age 12 to 15 using real-time region-specific data from Tumkur urban schools. This makes the model more 11 to local life style, culture and environment. A Key innovation is the use of physical fitness measures which offer a more dynamic and complete view of a child health. a novel aspect is the development of a mobile app for parents that provide real time health alerts personalized guidance and behaviour tips encouraging their active environment. The AI model built using neural networks can identify Complex health patrons and continuously improve with the new data ensuring I accuracy in detecting obesity risk early. by integrating this technology in the school, the study of a preventive community-based solution that supports long term improvements in child health and improves public health policy in India

Scope for Future Research and Extension
Expand target population:
Apply model to ages 6 to 11 and 16 to 18 for full childhood coverage.
Test in rural, semi urban areas and other developing countries.
Analyse impact across different social economic groups

Enhance data inputs:
Use Longitudinal data for long term prediction and outcomes.
Add genetic, epigenetic and environmental respects.
Integrate variable device data and the non-invasive biomarkers.
Employ AI based tools for detailed dietary assessments.
Advanced model development:

Explore advanced model like RNN, CNN models.
implement explainable AI for transparency and trust.
use adaptive AI to personalize interventions in real time

Strengthen intervention and evaluation:
Add gamification and social features to boost engagement.
enable clinical integration for Holistic Health Management.
perform cost effectiveness and ROI analysis.

Inform policy and public health:
Study scale ability for Regional or National implementation.
provide data driven recommendations for obesity prevention policies

Childhood Obesity Risk Prediction and Intervention Algorithm
This algorithm outlines a phased approach to leveraging conventional health indicators, novel fitness metrics, behavioral/environmental data, and real-time mobile app data to predict childhood obesity risk and provide personalized interventions.

Phase 1: System Initialization and Baseline Data Collection
This phase focuses on setting up the necessary infrastructure and gathering the initial dataset required to train the predictive model.

Step 1: Initialize System and Secure Approvals
This is a **one-time setup** for the entire system.
Secure Ethical Approvals: Obtain necessary approvals from Educational Authorities and the Institutional Ethics Board.
Obtain Informed Consent: Secure informed consent from parents of child participants.
Obtain Child Assent: Get assent from children aged 12-15 years participating from Tumkur Urban Schools.
Initialize Mobile Application Platform: Set up the parent-centric mobile application interface.

Step 2: Collect Initial Primary Data Snapshot
This step involves collecting baseline data for the initial model training.
For Each Child Participant:
Perform On-Site Physical Assessments: Record Conventional Health Indicators (BMI, Resting Heart Rate) and Novel Fitness Metrics (Vertical Jump Height, Field-Based Endurance Test Performance).
Administer Structured Questionnaire to Parent: Collect Behavioral Environmental Data Q (Dietary Patterns, Screen Time, Sleep Duration, Physical Activity (outside school), Family History, Psychological Well-being).
Register Child-Parent Pair on Mobile App.

Store All Initial Data: Compile and store all **collected Physical Assessments Data and Questionnaire Data.**
Phase 2: Data Preprocessing and Initial Deep Learning Model Training
This phase prepares the collected data and trains the foundational deep learning model.

Step 3: Preprocess Data
This step cleans and transforms the raw data for model consumption.
Input: Takes Raw Data Set (initially from Step 2, and later from Step 6 feedback).
Normalize Numerical Features: Apply normalization to numerical data (e.g., BMI, Heart Rate, Jump Height).
Handle Missing Values: Implement strategies for managing missing data (e.g., imputation, exclusion).
Encode Categorical Features: Convert categorical data into a numerical format suitable for the model (e.g., dietary patterns, activity levels).

Output: Produces Clean Processed Data.

Step 4: Train Deep Learning Neural Network (Initial)
This step involves building and training the core predictive model.
Input: Uses Clean Processed Data from Step 3.
Define Deep Learning NN Architecture:
Input Layer: Design with features including BMI, HR, Jump Height, Endurance, Behavioral data, and Environmental data.
Multiple Hidden Layers: Incorporate multiple hidden layers (e.g., with ReLU Activation).
Output Layer: Configure with 1 neuron and Sigmoid Activation to output the probability of obesity.
Split Data: Divide the Clean Processed Data into Training Set, Validation Set, and Test Set.

Train Model:
Loop Until Convergence or Max Epochs:
Train NN Model: Train the Neural Network model using the Training Set (Optimization: Backpropagation with a Gradient Descent Variant like Adam).
Evaluate NN Model Performance: Monitor Loss and Accuracy on the Validation Set.
Adjust Hyper parameters: Fine-tune hyper parameters as needed during the loop.
Test Final Model: Evaluate the Final Model Performance on the Test Set using metrics such as Accuracy, Precision, Recall, F1-Score, and AUC-ROC.
Output: Generates the Trained Deep Learning NN Model.

Phase 3: Real-time Risk Prediction and Intervention Loop
This ongoing phase deploys the model, continuously collects data, predicts risk, provides interventions, and self-improves.

Step 5: Deploy Model to Mobile Application
This is the initial deployment of the trained model for real-time use.
Input: Receives the Trained Deep Learning NN Model from Step 4.
Integrate Model API: Integrate the model's API into the Mobile Application Backend.
Set Mobile App Status: Set MOBILE_APP_STATUS to "Active."
Loop While MOBILE_APP_STATUS = "Active": This loop represents the continuous operation of the system.

Step 6: Collect Real-time App Data and Predict Risk
This step continuously collects data and generates real-time obesity risk scores.
Collect Mobile App Realtime Data: Continuously collect data on Daily Activity Levels, Parental Engagement, Adherence to Recommendations, and Child Progress from active users.
Formulate Current Child Profile: Combine the latest App Data with static baseline data to create a comprehensive profile.
Input: Uses the Current Child Profile (which is preprocessed by the app's backend or integrated preprocessing modules).
Run Trained Deep Learning NN Model: Execute the deployed model on the Current Child Profile.
Output: Produces the Obesity Risk Probability Score for the current child.

Step 7: Trigger Intervention and Feedback
Based on the predicted risk, appropriate interventions are triggered, and feedback data is collected for future improvement.
Input: Takes Obesity Risk Probability Score and Parent Child Profile.
Conditional Intervention Logic:
If Obesity_Risk_Probability_Score IS High (e.g., > 0.80) THEN:

SEND Immediate Parental Alert (via App).
GENERATE Highly Personalized Lifestyle Recommendations (Diet, Activity, Screen Time).
ELSE IF Obesity_Risk_Probability_Score IS Moderate (e.g., 0.20 - 0.80) THEN:
SEND Regular Progress Update to Parent (via App).
GENERATE Moderate Personalized Lifestyle Recommendations.
ELSE (Low Probability):
PROVIDE General Health Wellness Tips (via App).

Track Engagement and Progress:
TRACK Parent Engagement with App Recommendations.
TRACK Child Progress on Recommendations (as reported via app or next assessment).
Feedback Data Collection:
FEEDBACK_DATA is composed of Mobile App Realtime Data + Engagement Metrics + Progress Tracking.
ADD FEEDBACK_DATA to Existing Data Set for future retraining. This closes the continuous improvement loop.

Step 8: Periodically Retrain Model
This step ensures the model remains accurate and relevant over time by incorporating new data.
If Sufficient New Data Accumulated OR Scheduled Retraining Time THEN:
CALL Preprocess_Data: Run Step 3 using New and Accumulated Data.
CALL Train_Deep_Learning_Neural_Network: Run Step 4 using the Updated Clean Processed Data.
UPDATE Deployed Model: Replace the currently deployed model in Step 5 with the newly trained one.

Phase 4: Conclusion and Dissemination
This final phase focuses on analyzing the overall impact and sharing the findings.

Step 9: Disseminate Research Outcomes
Analyze Overall System Effectiveness: Evaluate the impact on obesity rates and behavioral changes.
Publish Findings in Academic Journals.
Formulate Policy Recommendations: Develop recommendations for public health initiatives.

Data Analysis and Interpretation (Gap Analysis)
This study begins with a comprehensive analysis of existing secondary data sources related to paediatric obesity, including published literature, public health records, and regional health surveys. By examining available datasets and prior research findings, key trends, risk factors, and limitations of current predictive models are identified. The analysis highlights a significant gap in region-specific, real-time data reflecting the physical fitness and lifestyle behaviours of Indian school children. Current models predominantly rely on generalized or global data sites and often use Limited static indicators which restricts their predictive accuracy and relevance to local. There is a lack of integrated data capturing parental involvement and real time monitoring of which are very crucial for effective early detection of obesity risk.

Recognising the gaps, the study proposes to collect primary data directly from getting children aged 12 to 15 years. The primary data collection will encompass detailed physical fitness assessment, Lifestyle questionnaire and real time monitoring via mobile health application. This approach aims to generate a rich region-specific data set that will enable the development of a more accurate and cultural tailor machine learning model for early obesity prediction.
The initial gap analysis in forms are Research Design by identifying critical data needs and guiding the subsequent phases of primary data collection, model

CONCLUSION

The study addresses critical gaps in childhood obesity prediction by emphasizing the need for region, d. traditional models relay primarily on BMI and generalized data sets for short in capturing the complex factors influencing obesity among the school children. by integrating simple physical fitness assessment, real and parents Centred intervention the proposed approach offers a poor precise and culturally relevant method for early risk of obesity. The planned collection of primary data from Tumkur urban schools will provide valuable insights into localised the lifestyle and health pattern and answering the accuracy and applicability of AI Triveni predictive models. this research AIIMS to shift the focus from reactive treatment to proactive prevention postering healthy or childhood development and informing target at public health policy in India

Table 1. Literature Review Summary

Author(s)	Methodology	Aim	Gap Analysis
Siddiqui et al. (2021)	Survey of ML/DL models (CNN, ANN, SVM, etc.) from >50 studies	To assess the accuracy and applications of AI in childhood obesity prediction	Lack of region-specific models, minimal integration of fitness and lifestyle data
Chatterjee et al. (2021)	Comparative study using ANN, SVM, and KNN	To evaluate early obesity prediction in toddlers using AI classifiers	Data focused on toddlers; no inclusion of fitness or longitudinal predictors
Dugan et al. (2015)	Random Forest, Naive Bayes, ID3 using infant clinical records	Early prediction of obesity before age 2 using structured EHRs	Limited to infant clinical variables; lacks application to school-aged children or real-time models
Cheng et al. (2022)	RNN and LSTM on time-series EHR data	To examine data sufficiency and accuracy for childhood obesity prediction	Focused on hospital data; did not explore real-time or physical fitness inputs
Gautam & Jeong (2019)	Cross-sectional analysis in Udupi (India)	To evaluate obesity prevalence and socioeconomic determinants among school children	No predictive modeling done; regional but lacks AI application
Garg & Pundir (2021)	IoT-based fitness tracker + XGBoost and Random Forest models	To deliver personalized obesity intervention using wearable and app integration	No regional context (India); no ANN-based modeling or school-centric data
Jeong et al. (2023)	DeepHealthNet (DL model using health, diet, and activity data)	To improve adolescent obesity prediction using multimodal inputs	High-performing model but lacks integration of simple field-based fitness metrics like jumping or endurance
Siddiqui et al. (2020)	CNN-based BMI prediction from facial images (ResNet, DenseNet)	To estimate BMI using visual input as an alternative to clinical measures	Novel method, but does not apply fitness or contextual behavior data
Logistic Regression Study (2019)	Statistical model with maternal and infant indicators	To predict childhood obesity risk based on early-life anthropometrics	No AI/ML usage; not suitable for app integration or school-aged prediction
Alturki et al. (2021)	Design of IoT-based mobile app for obesity management	To propose personalized, real-time feedback apps for pediatric weight control	Conceptual framework only; does not integrate Indian population or ANN methodology

Table 2. Connectivity Between Research Objectives and Literature Review Gaps

Objective	Literature Review Gap Addressed	Connectivity
1. Region-specific ANN model using physiological, behavioral, and environmental data	Existing studies lack models tailored to Indian populations and do not combine environmental or behavioral data effectively (e.g., Siddiqui[1], Dugan[3], Cheng[4])	Strong connectivity: Directly addresses region-specific and multidimensional data gaps
2. Integration of novel physical fitness metrics (e.g., jumping points, heart rate variability)	Fitness-based indicators are underexplored; most rely on BMI and static health indicators (e.g., Siddiqui[1], Jeong[7])	Unique connectivity: Adds a new layer of predictive variables overlooked by prior models
3. Design of parent-centric mobile app with real-time AI	Existing tools are limited in user interaction, parental involvement, and localized	Clear connectivity: Bridges prediction tools with real-world,

integration	implementation (e.g., Garg[6], Alturki[10])	user-friendly interfaces
4. Evaluate the effectiveness of AI and parental involvement on lifestyle outcomes	Few studies measure the actual impact of AI predictions on behavioral change or family-level intervention (e.g., Verma, Patel – 2023)	High connectivity: Integrates AI prediction with proactive and measurable health intervention outcomes

Table 3.CDC growth chart and BMI percentile interpretation

BMI Percentile Range	Classification	Interpretation
< 5th percentile	Underweight	Nutritional risk
5th – <85th percentile	Normal weight	Healthy range
85th – <95th percentile	Overweight (Pre-obese)	Early obesity risk
≥ 95th percentile	Obese	High risk of Health issues

Table 4. Neural Network Model Overview

Layer	Type	Neurons	Activation Function	Purpose
Input Layer	Dense	3	—	Inputs: BMI, Weight, Height
Hidden Layer 1	Dense	8	ReLU	Learns interaction patterns
Hidden Layer 2	Dense	6	ReLU	Extracts deeper representations
Output Layer	Dense	1	Sigmoid	Outputs probability of obesity classification

Table 5. Sigmoid Function

Activation Function	Used In	Output Range	Purpose
ReLU	Hidden Layers	0 to ∞	Fast learning, captures patterns
Sigmoid	Output Layer	0 to 1	Gives probability for classification

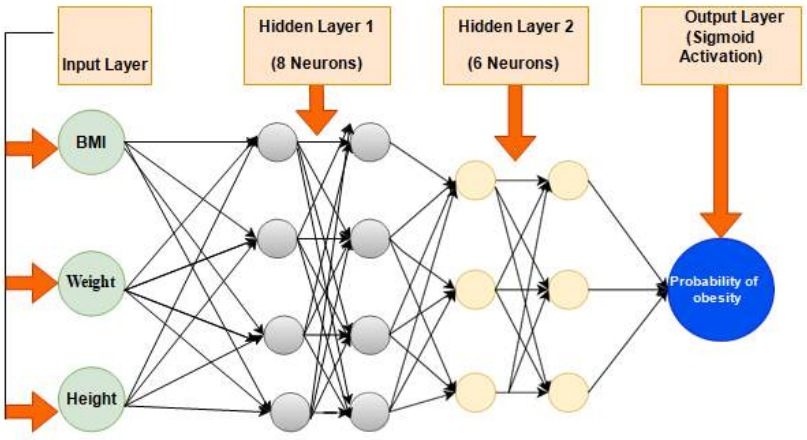

Fig.1. Neural Network (ANN) model

ABSTRACT

In the evolving landscape of cloud computing, ensuring secure data sharing remains a critical challenge. This paper presents a novel approach leveraging Secure Proof of Stake Blockchain with Elliptic Curve Cryptography (SPoS-ECC) to enhance data security in cloud environments. The proposed SPoS-ECC algorithm ensures efficient and secure data transmission by utilizing elliptic curve cryptography to generate public keys for each document, providing robust encryption with minimal computational overhead. To further enhance access control, the system incorporates Secure Policy Key Authorization (SPKA) which verifies each participating node based on predefined security policies. This dual-layered approach not only strengthens data confidentiality but also ensures the integrity of cloud storage by preventing unauthorized access. The proposed method offers a scalable and efficient solution for secure data sharing in centralized cloud infrastructures, addressing key challenges related to privacy, authentication, and data integrity. Experimental evaluations demonstrate that the SPoS-ECC-based framework significantly improves security performance compared to traditional encryption methods while maintaining computational efficiency.

Keywords: Cloud computing, secure data transmission, Authentication, verification, ECC,Secure Policy Key Authorization, Blockchain.

INTRODUCTION

In recent years, cloud computing has become an integral part of modern IT infrastructure, enabling organizations to store and access vast amounts of data remotely. However, with the increasing reliance on cloud services, data security has emerged as one of the most critical concerns. Ensuring the confidentiality, integrity, and authenticity of data stored in the cloud is paramount, especially when it comes to sensitive or personal information. Traditional methods of data protection often fall short in addressing the complex security challenges posed by cloud environments, such as unauthorized access, data tampering, and privacy violations. As a result, new approaches that provide robust security while maintaining efficiency are urgently needed. This paper presents an innovative approach to cloud data security, focusing on the utilization of a Secure Proof of Stake Blockchain with Elliptic Curve Cryptography (SPoS-ECC). By combining blockchain technology with elliptic curve cryptography, the proposed system introduces a highly secure and efficient mechanism for data encryption and access control. Blockchain's decentralized nature ensures that data is distributed across multiple nodes, making it resistant to tampering and unauthorized modifications. Furthermore, the incorporation of elliptic curve cryptography allows for the generation of public keys with relatively small key sizes, reducing computational overhead while maintaining a high level of encryption strength. A major feature of the proposed system is its dual-layered approach to security, which integrates two essential components: Secure Proof of Stake (SPoS) and Elliptic Curve Cryptography (ECC). The SPoS mechanism utilizes a consensus-based approach to validate transactions within the network, ensuring that only authorized participants can access or modify the data. On the other hand, ECC provides strong encryption, making it virtually impossible for malicious actors to decrypt sensitive data without the corresponding private key. ECC is based on the mathematical properties of elliptic curves over finite fields, where the security relies on the difficulty of solving the Elliptic Curve Discrete Logarithm Problem (ECDLP). This complexity makes it computationally infeasible for attackers to derive private keys from public keys, ensuring robust encryption, digital signatures, and key exchange mechanisms. ECC offers significant advantages, such as reduced computational overhead, lower power consumption, and faster performance, making it ideal for resource-constrained environments like mobile devices, IoT applications, and secure communications.

Popular ECC-based algorithms include ECDSA (Elliptic Curve Digital Signature Algorithm) for authentication and ECDH (Elliptic Curve Diffie-Hellman) for secure key exchange. Due to its efficiency and security, ECC is widely adopted in modern cryptographic standards, blockchain technology, and encrypted messaging applications. This dual-layered model not only strengthens the overall security of the cloud environment but also optimizes the performance by minimizing the computational load typically associated with traditional encryption techniques. In addition to ensuring secure encryption and authentication, the system introduces Secure Policy Key Authorization (SPKA) for advanced access control. SPKA enables the system to enforce security policies that define specific rules and permissions for each node within the cloud infrastructure. These policies ensure that only authorized users or nodes can access or alter specific documents, further preventing unauthorized access or data breaches. By utilizing predefined security policies, SPKA enhances the flexibility and scalability of the system, allowing it to be tailored to different organizational needs and security requirements. One of the key advantages of the SPoS-ECC framework is its ability to offer a scalable solution that can be adapted to various cloud infrastructures. The proposed approach is well-suited for both centralized and distributed cloud environments, providing an effective solution for enterprises looking to protect their data while ensuring that the system can handle an increasing number of users and data traffic. The scalability of the system makes it an attractive option for organizations that require secure data sharing on a large scale without sacrificing performance or efficiency. The experimental evaluations demonstrate the effectiveness of the SPoS-ECC-based framework in real-world scenarios. Comparisons with traditional encryption methods show that the proposed approach significantly improves security performance, especially in terms of preventing unauthorized access and ensuring data integrity. At the same time, the computational overhead remains minimal, allowing the system to operate efficiently even under heavy workloads. The results suggest that SPoS-ECC can serve as a reliable and high-performance solution for secure data sharing in cloud environments, addressing the critical challenges of privacy, authentication, and data integrity.

LITERATURE REVIEW

This research primarily aimed to critically assess and analyze claims regarding the current state-of-the-art in blockchain technology within the context of supply chain management. By comprehensively reviewing and synthesizing existing research, the study sought to identify systemic flaws and limitations within the existing literature. Building upon this foundation, the authors of study [1] delved into specific applications, exploring how blockchain technology could be effectively leveraged to enhance security services across the supply chain. Singh [2021][2]proposed block chain based distributed authentication mechanism process and network architecture. Medi-Block presents a tamperproof and anonymous identity management model for medical record sharing for hospitals and patients, utilizing the concept of bilinear mapping for the authentication phase and eliminating third party trust issues. It implements two-way authentications between the patients and the hospital. The effectiveness of the proposed authentication scheme is analyzed by BAN logic, storage overhead and computing cost. Mulani [2022] [3] proposed a multiagent architecture to enable straightforward, decentralized IoT access control security solutions. The responsibility for providing the necessary security for cloud computing, local IoT device connectivity, fog node security, core fog node security, and access control falls on blockchain management. The proposed architecture is a versatile strategy that may be applied to various IoT applications. Ma [4] proposed a blockchain-based security-oriented data-sharing scheme. Firstly, an architecture that separates data from data ownership is employed to enhance the security of the scheme and reduce storage overhead. Secondly, a lightweight on-chain and off-chain collaborative data security algorithm based on ECC and ECDHE is designed to ensure confidentiality during data sharing.

Finally, a mechanism for tracking the circulation of shared data is proposed, which records the data flow in non-fungible tokens (NFTs), thereby improving the traceability of the proposed scheme. Lee *et al*. [5] introduced a novel framework for secure healthcare data sharing. This framework leverages blockchain technology to manage a registry of medical centers, while utilizing the Fast Healthcare Interoperability Resources (FHIR) standard for efficient data exchange. By storing the registry on the blockchain, the framework enhances interoperability while maintaining the security and privacy of raw patient data, which remains within dedicated databases**.** Yang *et al*. [6] presented a novel blockchain-based framework for facilitating secure and efficient data sharing among heterogeneous network domains within the context of Industrial Internet of Things (IIoT) edge computing. This innovative framework incorporates a two-layer stacked network topology and leverages edge computing principles to optimize data processing and dissemination. A key feature of this framework is the utilization of blockchain technology to transparently and immutably record all data-sharing activities, ensuring data integrity and provenance. Alsobeh *et al.* [7] proposed a novel blockchain model verification method combining Aspect-Oriented Programming (AOP) with model checking. This enhanced security by enabling dynamic analysis and monitoring. While blockchain safeguarded data integrity, its openness raised data leakage concerns. Implementing robust cryptographic algorithms was crucial to address this**.** Wang *et al*. [8] proposed a blockchain-TEE medical data privacy protection and sharing scheme. This scheme enabled reliable incremental updates and validations, thereby enhancing the security and efficiency of the blockchain-mediated data-sharing process**.**

Gao [9]aimed to enhance the ciphertext processing capabilities of existing data delegation solutions based on blockchain and ABE. Additionally, it addresses the current limitations of ABCT technology. This includes its inability to verify re-encrypted ciphertext and ensure non-repudiation of transformation results**.** Molli[10] explored the fundamental principles of blockchain technology, including its cryptographic foundations, consensus mechanisms, and smart contracts, and how these features collectively enhanced data security and integrity. They examined real-world applications of blockchain in fields such as finance, supply chain management, and healthcare, highlighting its effectiveness in mitigating risks associated with data breaches and fraudulent activities. Ullah *et al*. [11] provided a comprehensive survey on ECC, discussing its applications, challenges, recent advances, and future trends. Their work highlights ECC's role in improving security for open communication networks and its integration into modern digital environments. Barman and Saha [12] proposed a DNA-encoded ECC system to bolster security in IoT

environments. Their approach combines ECC with DNA encoding to increase encryption complexity, addressing security vulnerabilities inherent in IoT devices. Kumar [13] explored the design and analysis of pairing-friendly elliptic curves for cryptographic primitives, aiming to achieve high-security levels with minimal key sizes and computational costs. This research is particularly relevant for resource-constrained environments where efficiency is paramount

METHODOLOGY

This section outlines a secure data transmission system for cloud environments. It leverages Secure Proof of Stake Blockchain with Elliptic Curve Cryptography (SPoS-ECC) for robust data protection. To enhance node verification efficiency, the system Secure Policy Key Authorization (SPKA). A key feature is the generation of a unique public key for each document (fig1). By integrating a trusted cloud provider within the blockchain, this framework enables secure and controlled cloud storage. This allows for the sharing of storage resources among individuals while strictly adhering to defined security policies and access controls. Ensuring secure access rights is paramount for peer-to-peer (P2P) verification as it forms a crucial part of gateway authentication. To overcome the limitations mentioned earlier, we propose a decentralized cloud storage solution based on Blockchain technology. This innovative approach aims to enhance security and integrity verification, thereby offering robust and reliable cloud storage services to both enterprises and individual users

a)Secure Proof of Stake Blockchain with Elliptic Curve Cryptography (SPoS-ECC)

In file-sharing systems, access is typically open, allowing all participating nodes to engage in transactions seamlessly. The system continuously monitors all active nodes within the network to ensure compliance and security. Inspired by the security potential of blockchain technology, a cryptographic framework utilizing the leveraging Secure Proof of Stake Blockchain with Elliptic Curve Cryptography (SPoS-ECC) is proposed for centralized cloud storage. This approach aims to enhance the integrity of access control mechanisms by leveraging robust encryption techniques and consensus protocols.

The key generation process for each document is defined by the following expression

$$\sum \emptyset = \quad (1)$$

The above formula is used to generate a unique key for each document and determine the user access level L_c. Assuming an internal key K_{int} the access control mechanism is described as

$$K_{int} = f(K_{lat} * P_{access}) = \quad (2)$$

Where

K_{int} represents the internal encryption key.

K_{lat} denotes the lattice-based key

P_{access} represents the policy-driven access parameter.

Further, we assume the lattice-based structure is defined by

$$K_{lat} = \{D_1, D_2, .. D_n\} \quad (3)$$

Here, the expression defines how the document Di is split into multiple segments for enhanced security and management in the cloud environment. The encryption of each file segment is performed using the following formula:

$$Enc(D) = Enc(K_{lat}) = \sum e^{K_{lat} In(K_{lat})} \quad (4)$$

Public Key Generation Process

The process of public key generation involves verifying the sealing on the header of each block. Every block undergoes social consolidation, and the hash block integrates critical security factors through the key generation (keygen) function. This keygen inclusion securely encodes the contents based on material records within the blockchain system.

The key generation process follows these steps

Initialization
Generate two large prime numbers A and B, such that
$Key = A \times B$ (5)

Block Verification
Check if B==0; if true, increase the round key using
$\omega[0, Key - 1]$ (6)

Pattern Key Formalization
Add pattern key in the format
$\omega \times P, (P + 1) \times P - 1$ (7)

Public Key Retrieval
Derive the final public key and store it securely.

Hash Verification
The generated hash code is used to check the block header data at each level of storage.

Secure Policy Key Authorization (SPKA)
In this model, the Data Owner is responsible for setting up the system and granting access control (AC) to authorized users. Additionally, data owners manage file uploads to the cloud with access control policies in place. The file collection process is mathematically expressed as
$F = \{D_1, D_2, D_3, \dots D_n\}$ (8)
The authentication for each block is defined by
$Auth = Enc(K_{int})|Policy_{user}| \oplus Access_{control}$ (9)
Once authentication is complete, each block key undergoes verification using the formula:
$Verify(F) = Hash(F_i) \times Auth\%Security_{param}$ (10)

RESULTS AND DISCUSSION

This scenario investigates the design and development of a custom setup tool for deploying applications. These applications are designed to interact with a SQL Server database and are initially developed to run on hardware with performance comparable to a Pentium processor. However, the deployment tool is intended to deploy these applications on more powerful virtual machines, such as the 'i3' instance type, to enhance performance in the cloud environment. The tables compare the performance of three encryption methods: AES, DSA, and SPoS-ECC, across varying user loads. SPoS-ECC consistently demonstrates the highest success rate or efficiency, with its performance advantage increasing significantly as the user count grows. This suggests that SPoS-ECC may be a more efficient and scalable option for applications requiring high throughput and the ability to handle large numbers of users. Graphical presentation of Security Presentation (Fig 2). The table 1 compares the presentation of three encryption algorithms: AES, DSA, and SPoS-ECC, across different user loads. For 10 users, SPoS-ECC achieves a 73% success rate, significantly higher than AES (56%) and DSA (68%). This performance advantage grows with increasing user numbers. With 20 users, SPoS-ECC reaches 82% success, while AES and DSA manage 67% and 72%, respectively. At 30 users, SPoS-ECC maintains a strong lead at 86%, compared to 73% for AES and 78% for DSA. Finally, with 40 users, SPoS-ECC achieves an impressive 92% success rate, surpassing AES (78%) and DSA (86%). These results demonstrate SPoS-ECC superior efficiency and scalability, particularly in high-user environments. Graphical Presentation of Key Generation Performance (Fig 3). Table 2 presents a comparison of key generation performance for three encryption methods: AES, DSA, and SPOS-ECC, across varying user loads. The results, expressed as percentages, demonstrate that SPOS-ECC consistently outperforms both AES and DSA. With 10 users, SPOS-ECC achieves a 73% success rate, significantly higher than AES (55%) and DSA (66%). This performance advantage grows

with increasing user numbers. At 20 users, SPOS-ECC reaches 82%, while AES and DSA manage 66% and 75%, respectively. This trend continues with 30 users, where SPOS-ECC maintains a strong lead at 89%, compared to 73% for AES and 79% for DSA. Finally, with 40 users, SPOS-ECC achieves an impressive 94% success rate, surpassing AES (80%) and DSA (84%).These findings strongly suggest that SPOS-ECC offers superior key generation performance, particularly in scenarios with high user volumes, making it a more efficient and scalable option for various cryptographic applications. Graphical Presentation of Time Complexity (Fig 4). Table 3 analyzes the time complexity performance of three encryption methods: AES, DSA, and SPOS-ECC, across varying user loads. Time complexity is measured in seconds. Table 3 demonstrates that SPOS-ECC exhibits superior time complexity performance compared to AES and DSA across different user loads. This suggests that SPOS-ECC is a more efficient and potentially more scalable option for applications that require fast encryption and decryption operations, particularly in scenarios with high user volumes. Table 4 demonstrates that SPOS-ECC exhibits exceptional encryption and decryption performance across all user loads. With 10 users, SPOS-ECC achieves an impressive 78.5% encryption efficiency and 77.1% decryption efficiency. This performance consistently improves with increasing user numbers. At 20 users, SPOS-ECC reaches 83.1% encryption and 83.4% decryption efficiency. This trend continues with 30 users, where SPOS-ECC maintains a strong lead at 87.6% encryption and 88.7% decryption. Finally, with 40 users, SPOS-ECC achieves an outstanding 93.5% encryption and 94.8% decryption efficiency. These results highlight SPOS-ECC's exceptional performance in both encryption and decryption, particularly in high-user environments.

CONCLUSION

This novel approach utilizes a Blockchain-based Proof-of-Staking with Elliptic Curve Encryption (SPOS-ECC) algorithm to secure data transmission in the cloud. This method efficiently verifies each node using Secure Policy Key Authorization (SPKA). Furthermore, it generates a unique public key for each document. Simulation results demonstrate exceptional performance with 92% security, 23-second time complexity, and 94% key generation success. These findings, supported by Tables ItoIV, highlight SPOS-ECC's superior performance across key metrics, surpassing conventional methods like AES and DSA. SPOS-ECC exhibits enhanced security, reduced latency, and improved scalability, making it a promising candidate for secure and efficient data transmission in diverse cloud environments.

ABSTRACT

The research explores the various relationships between workplace stress, burnout, employee well-being, and strategies across various industries, including healthcare, education, hospitality, and public services. It is based on important research that highlights how positive work environments, team collaboration, psychological capital, and stress management practices can significantly reduce or mitigate the work burnout and improve employee performance and job satisfaction. The Research mainly highlights the role of organizational strategies such as well-being policies, flexible work arrangements, career management systems, and stress training programs in mitigating and reducing the stress-related outcomes. Demographic factors like age, gender, job experience, and education level also influence how the employees cope with stress and how they experience it. The Studies provide the importance of the person-job as well as person-organization also to mitigate burnout. Overall, Findings are a necessity for motivated and modified stress management approaches to certify sustainable employee well-being and organizational productivity.

Keywords : Work burnout, Stress management, Job stress, Mitigation of workplace burnout,Employee Engagement, Employee Retention.

INTRODUCTION

In the Current Digital Era, workplace burnout is a growing concern across the world, affecting employees' well-being, productivity. HR contributes an important role in mitigating burnout by implementing strategies for well-being and job satisfaction of t. Burnout can lead to turnover and reduce productivity, it affects the organizational performance. HR can help in identifying burnout and develop targeted strategies. By analysing the requirements to maintain stress and encouraging work life balance, HR can help reduce burnout risk. Effective HR strategies can help in employee engagement and overall well-being. HR's role in mitigating burnout is creating a healthy work environment. By making employee well-being organizations can create benefits such as improved morale, increased productivity, and reduced turnover. HR's can help to mitigate burnout as well as increase a positive work environment.

HR can implement various initiatives such as employee wellness programs, flexible work arrangements, employee recognition and reward systems. HR can also provide training and development opportunities to help employees career and improve skills. Overall, HR's role in mitigating burnout is important for creating a healthy, productive, and positive work environment. Effective HR strategies can also help reduce absenteeism, turnover, and recruitment costs. By promoting employee well-being, organizations grow long-term benefits and improve their competitive advantage. HR's role in mitigating burnout is critical for achieving these outcomes. By taking a proactive and strategic approach, HR can help organizations thrive and succeed.

REVIEW OF LITERATURE

1. Jenna Saud and John Rice (2024) It is to find the employee's wellbeing and effect of teamwork in the workplace, the supportive work environment and organizational strategy can reduce the work burnout. Team support can help to reduce burnout, Undergoing well-being can improve employee health and job satisfaction. The study's results have been connected with research on factors, such as age and gender.
2. Maja rozman et.al. (2019) Burnout is an important thing in the Information Technology field. Important aspects of contributing to burnout are the role uncertainty, role conflict, and job tasks. The studies have shown that these factors can contribute to increased burnout risk, and the need for managers to always be aware and mention these problems to improve individual well-being and organizational benefits.
3. RajasshrieSuresshDhobale (2009) The research is showcasing the importance of stress management occurring in the workplace environment. It is mainly focusing on how the training helps employees handle their stress properly, boosting and improving their well-being and productivity. These programs also reduce absenteeism and improve work environment morale effectively.
4. Akanksha Jaiswal et.al. (2022) It explores the impact of work from home arrangements in the period of COVID-19 pandemic on employee stress, well-being, resilience, and boundary management. It focuses on the fact that supportive organizational practices, such as flexible work policies, empathetic leadership, and access to mental health resources enhance employee well-being in crisis scenarios. It understands the employee adjustment mechanisms in the unplanned remote work environments and provides a theoretical foundation for future explorations in hybrid work models.
5. Behdin Nowrouzi et.al. (2015)Generally the medical field and medical centres are the most stressful places for people. They get stressed for different reasons at different times, particularly in the medical field nurses are people who get more stressed due to the environment, people, work, situation etc. This article talks about occupational stress management and burnout in nursing and implications for healthy work environments. They also gave implications for healthy and peaceful work environments to avoid & reduce burnout.
6. Dr. Kavyashree and Janeesa Abdulla (2024) Many studies have looked into the variables affecting faculty members' stress levels and the effectiveness of various stress-reduction techniques. Elements The truth Affects Stress According to research, a number of factors, such as workload, institutional support, and personal life

issues, might affect faculty members' stress levels. The impact of workload and institutional support are two recurring themes that come up, however their lack of uniformity in stress management measurement emphasizes the need for more study in this field.

7. Akintunde-Adeyi Julianah Funmilayo et.al.(2023) It is about how stress affects employees working at a private university in Nigeria. It found that stress has a big impact on employee performance, showing that managing stress is very important. It also talks about how managing stress can help employees do better at their jobs and suggests both the employees and the organization should work together to handle stress. It recommends useful ways to manage stress, like updating company policies, offering regular training, and checking if employees have too much work.
8. Mustafa Aslan et.al. (2022)The study is about when employees have too much work and can't keep up, it can lead to stress and a feeling of being trapped with 621 call center workers in Turkey. Career support helps reduce stress more for employees with university degrees than for those with only a high school diploma. Newer employees feel less trapped when there's a clear plan for their future at the company compared to those who've been there longer. Employees who have worked longer often feel more trapped, so companies should pay attention to their stress and concerns
9. Laiba Asif and Tayyeb Ali (2024)The study explores how stress management, work life balance, and psychological capital affect employee well-being among IT professionals at Pakistan. The research highlights that employees with higher psychological capital comprising hope, resilience, self-efficacy, and optimism are better equipped to handle stress as well as maintain a healthy work life balance, leading to improved or increased well being of the IT Professionals. This study emphasizes the importance of building psychological resources within the organizations to support employee health and productivity.
10. Pariona-Cabrera et al. (2023) The study is about how the Workplace violence is a growing concern in the healthcare sector, contributing significantly to job stress among health care workers. This stress can negatively affect both employee wellbeing and the quality of patient care. Study found that wellbeing-oriented HRM practices such as supportive management, counseling services, and stress management training can buffer the negative effects of workplace violence.
11. Wagih Salama et.al. (2022) This research aims to know the impact of work stress and job burnout on employee turnover in the hotel industry. With the factors of demographic characteristics, work stress items, job burnout items and turnover intentions. The results show the job burnout among stress in work and turnover. The findings of this study would help policymakers, hotel managers as well as practitioners to formulate policies for lessening the work stress, job burnout, and turnover intentions among hotel employees.
12. Panpan Zeng and Xiaoli Hu (2024)It says that personal jobs are negatively related to stressful jobs and work pressure, while work pressure directly relates to job burnout, mediating the relationship between personal job fit and job burnout. Similarly, person–organization is also negatively related to job burnout and work pressure. These findings are consistent with the person–environment theory, enhancing our understanding of how individuals relate with their jobs and how job burnout through work pressure.
13. Arik Prasetya, et.al. (2021) The study of the impact of work stress and burnout on job satisfaction and employee performance. Negative Impact of Work Stress and Negative Impact of Burnout negatively impacts job satisfaction. Positive Influence of Job Satisfaction has a significant positive effect on employee performance. Overall The combined effects burnout and job satisfaction influence employee performance among the healthcare professionals studied.
14. Karin Calitz (2022)Thestudyaddresses the issue of burnout in the workplace. This condition has reached high levels in many countries and affects the health and well-being of individuals, their families, workplaces, and the broader economy. They identify several dimensions of burnout such as Mental and Physical Exhaustion a state of extreme fatigue that affects both mental and physical health. A negative attitude towards work and colleagues and Reduced Accomplishment. It suggests that South Africa could benefit from adopting measures found in European health and safety legislation, as well as legal precedents from Australia and the United Kingdom, which emphasize employer responsibilities regarding employee mental health.
15. Umarani, C. and JayashreeG (2024) The studytries to identify the factors affecting the balance and suggests what all can be done to avoid the situation to have a balanced professional and personal life.

Objectives of the study

1. To review and examine the concept of stress management and find out the causes and consequences.
2. To explore the relationships between workplace stress, burnout, employee well-being, and strategies across various industries, including healthcare, education, hospitality, and public services.
3. To provide suggestions and techniques to mitigate workplace burnout.

Concepts

Stress management

Stress management are the techniques and strategies which are to tackle stress, reducing its impact on physical and mental health. Effective stress management can improve overall wellbeing, productivity, and a nice life. Workplace stress is a physical, emotional, or mental burden by employees because of some important factors. It can arise from too much workload, loss in control, poor work-life balance, or an Inflexible work environment. Stress reduces the employee's well-being, productivity, and job satisfaction. The important workplace stress symptoms are anxiety, anger, fatigue, and low motivation. Workplace stress can create burnout, bring down productivity, and employment turnover. Employers can reduce stress by promoting worklife balance, providing support, as well as providing a great work environment to employees. They can manage stress through self-care, time management, and getting support. By highlighting workplace stress, employers can increase productivity and employment turnover. A benefit of a good work environment will be delivered for both employees and the organization.

Workplace burnout:-

Workplace burnout is a zone of emotional, mental, and physical exhaustion affected by endless stress, overwork, and lack of balance in life. It can result in feelings of hopelessness, detachment, and cynicism towards work.

Causes of Workplace Burnout:

1. Workload: Over expectations, high pressure in the workplace and long working hours.
2. Lack of control: Lack of freedom and limited decision-making authority.
3. Poor work-life balance: Unable to balance work leading to burnout.
4. Unsatisfying work: Lack of meaning, purpose or fulfillment in work.
5. Poor work environment: Unhealthy, unsupportive or abusive work environment.

Consequences of Workplace Burnout:

1. Lower productivity: Burnout creates lower job performance and productivity.
2. Turnover: Burnout creates employee turnover, recruitment and training costs.
3. Health issues: Burnout creates physical and mental health issues.
4. Difficulty relationships: Burnout creates Untrusty relationships with family, and friends.

Prevention of Workplace Burnout:

1. Self-care: Focusing self-care, exercise, and relaxation techniques.
2. Setting boundaries: Setting boundaries between work life as well as personal life.
3. Communication: Communicate openly with managers about workload and stress.
4. Support: Get support from mentors, or professionals.
5. Change of workplace: Implement changes to reduce workload and improve the work environment.

Stress Management Techniques:

1. Deep breathing: Slow, deliberate breathing to calm the mind and body.
2. Physical exercise: Regular exercise to reduce stress and improve mood.
3. Meditation: Focus on the present moment to reduce stress and anxiety.
4. Time management: focuses on the tasks, sets realistic goals, and manages time effectively.
5. Social connections: Connect with family or friends to share feelings and experiences.

6. Relaxation: Continuous muscle relaxation, or yoga to increase relaxation and relief.
7. Healthy sleep: Establish the good sleep schedule and create a relaxing Sleep routine.

Key Responsibilities of HR in employee stress management:
1. Find the core: Recognizing workplace stress and developing the strategies to reduce them.
2. Promotes policies: Creating and implementing policies to manage workplace stress.
3. Providing support: Providing some socially connected activities like Counselling etc.
4. work life balance: Maintain work life balance through flexible work .
5. Training & development: promoting training and development to employees to reduce or manage stress and increase their well-being.
6. Monitoring and evaluation: Monitoring the effectiveness of stress management and evaluating their impact on employee well-being.

FINDINGS

Stress, Teamwork, and Wellbeing Policies (Saud & Rice, 2024)
It is to find the employee's well-being and effect of teamwork in the workplace, the supportive work environment and organizational strategy can Mitigate work burnout. Team support can help to reduce burnout, Undergoing well-being can improve employee health and job satisfaction. The study's results have been connected with research on the factors, such as age and gender. Overall, the study says the importance of team environments and well-being to mitigate work burnout in high-stress work environments.

Occupational Stress and Burnout in IT (Rozman et al., 2019)
Role uncertainty refers to uncertain expectations, unexpected job responsibilities or lack of clarity in job responsibilities, while role conflict is conflict of expectations. Job tasks, all about the workload and work stress, work burnout and difficulty. The studies have shown that these can contribute to improve burnout risk, and the need for managers to always be ready and mention these problems to increase individual well-being and organizational benefits. By improving employee well-being organizations mitigate turnover and improve productivity.

Stress Management Training (Dhobale, 2009)
The research shows the significance of stress management at workplace environment. It is focusing on how the training helps employees to handle their stress properly, increase and improve their well-being and productivity. These programs also reduce absenteeism and improve work environment morale effectively.

Forced Work from Home and Wellbeing (Jaiswal et al., 2022)
It explores the impact of forced work from home arrangements during the COVID-19 on employee stress, well-being, flexibility, and boundary management. The study says that employees experienced higher levels of stress due to unclear boundaries, increased digital workload, and social isolation.

Nursing Stress and Burnout (Nowrouzi et al., 2015)
Generally the medical field and medical centres are the most stressful places for people. This report talks about Occupational Management and Burnout interference in nursing and the healthy Work surroundings.

Stress in Higher Education (Kavyashree & Abdulla, 2024)
Research on stress management has become important, especially in the setting of higher education. Many studies have looked into the variables affecting faculty members' stress levels and the effectiveness of various stress-reduction techniques. Elements The truth Affects Stress According to research, a number of factors, such as workload, institutional support, and personal life issues, might affect faculty members' stress levels. Stress management is a complex topic that differs greatly between people and organizations.

Stress and Employee Performance in Nigeria (Funmilayo et al.)
It found that stress has a big impact on employee performance, showing that managing stress is very important. It explains what stress is, what causes it, the signs to look out for, and how to deal with it. It also talks about how managing stress can help employees do better at their jobs. The article suggests that both the employees and the organization should work together to handle stress. In the end, it recommends useful ways to manage stress, like updating company policies, offering regular training, and checking if employees have too much work.

Career Management and Entrapment (Aslan et al., 2022)
Good career management and succession planning both help lower stress and reduce the feeling of being stuck in a job.Stress plays a key role in how career systems and future planning affect how trapped employees feel.Career support helps reduce stress more for employees with university degrees than for those with only a high school diploma. Newer employees feel less trapped when there's a clear plan for their future at the company compared to those who've been there longer. Employees who have worked longer often feel more trapped, so companies should pay attention to their stress and concerns about job security.

Psychological Capital and IT Employee Wellbeing (Asif & Ali, 2024)
The study explores how stress management, work life balance, and psychological capital affect employee well being among IT professionals in Pakistan. The research highlights that employees with higher psychological capital comprising hope, resilience, self-efficacy, and optimism are better equipped to handle stress and maintain a healthy work-life balance, leading to improved and increased well-being of the IT Professionals. This study emphasizes the importance of building psychological resources within the organizations to support employee health and productivity.

Workplace Violence in Healthcare (Pariona-Cabrera et al., 2023)
It says how the Workplace violence is a growing concern in the healthcare sector, contributing significantly to job stress among health care workers. This stress can negatively affect both employee wellbeing and the quality of patient care. Study found that wellbeing-oriented HRM practices such as supportive management, counseling services, and stress management training can buffer the negative effects of workplace violence. These practices help reduce stress levels and improve resilience, highlighting the importance of proactive HR strategies in healthcare settings.

Stress, Burnout, and Turnover in Hotels (Wagih Salama et al., 2022)
With the factors of demographic characteristics, work stress items, job burnout items and turnover intentions. The results show the job burnout among work stress and turnover target. The findings of this study would help policymakers, hotel managers as well as practitioners to formulate policies for lessening the work stress, job burnout, and turnover intentions among hotel employees.

Person–Job Fit and Burnout (Zeng & Hu, 2024)
The findings reveal that personal jobs are negatively related with job burnout and work pressure, while work pressure positively relates to job burnout, and mediating the relationship between personal job and job burnout. Similarly, person–organization negatively affects job burnout as well as work pressure.

Stress, Burnout, and Job Satisfaction (Prasetya et al., 2021)
The combined effects of work stress, burnout, and job satisfaction influence employee performance among the healthcare professionals studied. The study analysis for data evaluation highlighting the critical similarities of stress, burnout, job satisfaction, and performance in the healthcare sector.

Burnout in the Workplace (Calitz, 2022)
This condition has reached high levels in many countries and affects the health and well-being of individuals, their families, workplaces, and the broader economy. They identify several dimensions of burnout such as Mental and

Physical Exhaustion. It suggests that South Africa could benefit from adopting measures found in European health and safety legislation, as well as legal precedents from Australia and the United Kingdom, which emphasize employer responsibilities regarding employee mental health.

Work Life Balance (Umarani, C.& JayashreeG 2024)
The study suggested thatsatisfaction level of the employees is a critical factor at the work place where a HR manager needs to pay attention on it.

SUGGESTIONS

Implement Stress Management Training Programs
Organizations provide basic stress management programs to help employees develop to tackle the strategies and improve their overall well-being. These programs can include techniques such as mindfulness, meditation, and deep breathing exercises. By attending stress management training, organizations can reduce absenteeism, improve productivity, and enhance employee job satisfaction.

Foster a Supportive Team Environment
It is to mitigate burnout and stress among employees. Organizations encourage teamwork, provide a good environment and will support employees. This can be made by recognizing and rewarding team achievements, providing some opportunities for team-building activities, etc. By doing so, organizations can make a sense of belonging and friendship among employees, which can help mitigate stress and burnout.

Promote Work Life Balance
Achieving a healthy work life balance is important for employee well-being. The organizations have to provide possible policies, such as telecommuting options, maintainable work hours, and unstressful workweeks, to help employees balance their work and personal responsibilities. By promoting work life balance, organisations can Mitigate stress, enhance employee satisfaction, and increase capacity.

Develop Effective Career Management and Succession Planning
It can help reduce stress and job traps among employees. Organizations should provide clear career paths, planning, and support to help for their development of skills and futuristic skills in their careers. By doing so, organizations can increase employee engagement, retention, and productivity.

Build Psychological Capital
Psychological capital, including hope, confidence, and resilience, is important for employee well-being. Organizations should make psychological capital through providing opportunities for employee development, recognizing and appreciating employee achievements, and promoting a positive work environment. By providing psychological capital, organizations can help employees manage stress, improve their well-being, and increase their productivity.

Adopt Well Being-Focused HRM Practices
Organizations should adopt well-being-focused HRM practices, such as counseling services, stress management training, and employee wellness programs, to support employee well-being. These can help to reduce stress, improve employee satisfaction and increase productivity. By providing some attention to the employee well-being, organizations can create a positive work environment that supports employee health and well-being.

Reduce Role of Uncertainty and Conflict
Role of uncertainty and conflict will contribute to stress as well as burnout among employees. Organizations should clearly define job roles, expectations, and responsibilities to reduce role uncertainty and conflict. By doing so,

organizations can help employees understand their roles and responsibilities, reduce stress, and improve productivity. This can be achieved by providing clear job descriptions, regular feedback, and opportunities for employee development.

CONCLUSION

Stress management is prime in the prevention of burnout while being fundamental to employee wellbeing and organizational productivity. Supportive working environments that foster teamwork provide clear definitions of roles, offer training for stress management, and organizational policies devoid of hard frameworks can reduce the likelihood of burnout in the digital era. Further, compassionate authority and wellbeing-centered HRM policies can aid employees. The alignment of organizational and employee value also employee wellbeing, alongside effective planning for succession and psychological resource building. As highlighted, organizational focus on employee wellbeing enables improved job satisfaction, increased productivity, lowered turnover intention, and enhanced psychosocial job performance. Establishing policies that encourage the safeguarding of mental health and burnout mitigation takes precedence. There is a need for meaningful attention and resource support directed at employee development and overall well-being. A wellbeing culture supports employees and ultimately enhances organizational productivity and success. Hence, the organization becomes a success and strives to emerge as an industry benchmark. Addressing the critical approach of wellbeing in conjunction to aligned business strategy creates unprecedented results in employee wellbeing. Taking the necessary steps of managing stress and burnout enables sustainable organizational benefit over time. Wellbeing, as seen, steers organizational success, demanding the focused spotlight of attention and capital investment. Wellbeing protection when prioritized enables employee performance improvement.

ABSTRACT

Over the past few decades, extensive efforts in drug discovery have resulted in the development of numerous therapeutic molecules aimed at addressing various healthcare challenges. However, a significant proportion of these drugs fall under Class II and Class IV of the Biopharmaceutical Classification System (BCS), indicating poor solubility or permeability issues. Nanotechnological strategies have emerged as promising solutions, with lipoidal formulations demonstrating particular suitability for enhancing the delivery of such drugs. Among these, nanoemulsion-based gels known as nanoemulgels have gained attention as an effective approach for topical drug delivery. Nanoemulgels are essentially oil-in-water nanoemulsions incorporated into a gel matrix using suitable gelling agents. This gel phase is non-greasy, offers better patient compliance, and enhances formulation stability by lowering surface and interfacial tension. Moreover, nanoemulgels enable site-specific drug delivery, bypass first-pass metabolism, and minimize gastrointestinal or systemic side effects. This review focuses on the components, pros and cons, characterization techniques of nanoemulgels as a modern and efficient drug delivery system.

Keywords Nanoemulgel; Nanoemulsion; Transdermal drug delivery, topical route,

INTRODUCTION

Throughout the history of ancient medicine, the skin has been recognized as a vital route for administering various therapeutic agents to achieve desired medicinal effects. In modern healthcare, this concept has evolved into the Transdermal Drug Delivery System (TDDS), which has become a valuable alternative to traditional oral drug delivery methods. Over the past few decades, TDDS has played a significant role in improving therapeutic outcomes

and patient compliance. To address the challenges associated with the delivery of newly developed drugs, transdermal delivery systems have undergone continuous advancements, leading to the evolution of first-, second-, and third-generation TDDS. These generations are categorized based on factors such as the size and physicochemical characteristics of the active pharmaceutical ingredients, the technological approaches employed, and the use of different chemical or physical penetration enhancers. This progressive development reflects the ongoing innovation in transdermal drug delivery aimed at overcoming formulation and absorption challenges. [1].

Nanoemulgels

Nanolipoidal delivery systems are one of the novel delivery systems, used not only for bioavailability enhancement but also for various stability purposes [2, 3]. Among the various nanolipoidal delivery systems like Solid Lipid Nanoparticles (SLNs), liposomes, micro emulsion, Nanostructured Lipid Carriers (NLCs) etc., nanoemulsion is one of the most successful delivery systems for lipophilic and low bioavailable drugs administering through various routes including the topical route. As far as transdermal delivery is concerned, a pharmaceutically modified form of nanoemulsion with the incorporation of a suitable gelling agent can be a better choice for BCS class II and/or IV drugs.

A nanoemulsion with a gelling agent is better known as nanoemulgel. Here the water content of gel can convert the emulsion into an emulgel. Keeping the size of emulsion droplets under 500nm, the tendency of droplets separation will be very less as compared to general emulsion [4, 5].Nanoemulsions are optically either transparent or translucent isotropic systems composed of various categories of lipids, surfactants and co-surfactants. Nanoemulsion can be of two types either oil in water (O/W) or water in oil (W/O) and globules are found in the size range of 5-500nm. Processing such a composition of the material and having a nanoscale size range of globules, these nanoemulsions are now gaining significant scientific attention for various properties like enhanced stability, better solubility enhancement capacity, extemporaneous formation and high drug loading capacity of both hydrophobic and hydrophilic drugs [6, 7].For the nanolipoidal delivery through the skin, a gel-based nanoemulsion known as nanoemulgel can be a preferred drug delivery system because of its excellent properties like easy spreadability, thixotropic behavior, being greaseless, easily removable, biocompatibility etc.

Pros [8]

1. Stability of Nanoemulsion is enhanced due to distribution of oil droplets in Gel base; where affinity of the drug toward oil determines stability.
2. Also good adhesion on the skin with high solubilizing power leads to high concentration gradient that increase penetration of drug as it moves down.
3. These types of formulation gives support to delivery of lipophilic and poorly water soluble drugs.
4. Improve patient compliance.
5. Helps in controlled release of drugs which are having the shorter half-life.
6. Higher Spreadability of the formulation than creams.
7. Nontoxic and non-irritant.
8. Loading of drug compare to other formulations is better.
9. Increase in skin permeability and drug deposition.

Cons [9]

1. Skin irritation on contact dermatitis.
2. Bubbles formed during emulgel formulation.
3. Possibility of allergenic reactions.
4. Drugs having large particle size (>400 daltons) are not easily absorb or cross through the skin barrier.

Components of Nano emulgels

Formulation of nanoemulgel for the purpose of drug delivery through topical route requires a variety of materials suitable and compatible with the skin along with consideration of some important factors such as the amount of drug

to be loaded, amount of water to be used and route of permeation of the drug through the skin. A gel-based nanoemulsion formulation for topical use consists of some special materials other than lipids and surfactants such as gelling agent, penetration enhancers, preservative and anti-oxidants. These penetration enhancers actually compromise the skin barriers and help the drug to enter systemic routes finally achieving the desired therapeutic concentration.

Aqueous Phase

For the formulation of nanoemulgel, most commonly distilled water or ultra-purified water is used as the aqueous phase and this phase is responsible for the conversion of emulsion form into the emulgel in the presence of a gelling agent [10].

Oil phase

In the preparation of nano emulgels, important component of the nanoemulgel is the lipid component, i.e., oil. There is requirement to select an appropriate oil phase based on viscosity, permeability, and stability of the formulated nanoemulsion. Sometimes selection of oil phase is also dependent on utilization of the medicinal property of some natural oils . Based on the source of the oil, it has been observed that vegetable oils (of long-chain fatty acids) had poor emulsification properties, therefore result in unstable nanoemulsion [11, 12]. On the other hand, emulsification property was found to be better when the oil was with less hydrophobic property [13]. Contrary, increased hydrophobicity affects the solubility of the lipophilic drugs in it. Therefore, selection of appropriate oil is a critical step in formulation development.

Examples of some of the used oils in preparation of nano emulsions are castor oil, tea tree oil, oleic acid and various fixed oils (cottonseed oil, maize oils, arachis oil) emu oil, eucalyptus and eugenol Oils, capryol 90, labrafac etc.

Surfactants and Co-surfactants

In the fabrication of nanoemulgel, the role of surfactants is to stabilize the final formulation as well as to help in the solubility of the drug used. For the said purpose, the surfactants can be of different chemical nature such as cationic, anionic and non-ionic. Because of their role of emulsification, these surfactants are known as emulsifiers. Sorbitan fatty acid esters and polyoxyethylene sorbitan fatty acid esters are non-ionic surfactants and are preferably used in the preparation of nanoemulgel.

In this category. Tween 20, Tween 80 and span 80 are commonly used for the said purpose. Other preferable nonionic emulsifiers include various castor oil derivatives such as Cremophore EL and Cremophore RH, Labrasol, Labrafac, Poloxamar 124 and 188 etc. Selection of emulsifiers in nanoemulsion preparation is a serious issue and is associated with some toxicity factors. The increased amount of surfactants can lead to irritation of skin and hence causing uneasiness. Non-ionic surfactants are mostly preferred because of their comparatively lower toxicity than ionic surfactants [14]. Co-surfactants are mainly used for the purpose of decreasing the concentration of surfactants as well as for better thermodynamic stability of the final formulation. Preferred cosurfactants for the nanoemulgel formulation include Transcutol HP, PEGs, glycerine, PGs, and ethyl alcohol.

Permeation Enhancers

The use of permeation or penetration enhancer is one of the better ways to improve the rate of transport through the skin and related layers [15]. Permeation enhancers are one of the main components of the topical drug delivery system and are preferably used in topical nano emulsion or nano emulgel. These permeation enhancers mainly function by interacting with skin constituents and induce a temporary and reversible increase in skin permeability. It also provides an added driving force for the transport of drug into the skin [16]. Permeation enhancer used for the nano emulgel includes isopropyl myristate, linoleic acid, oleic acid, lecithin etc.

Gelling Agents

The gelling agent is one of the major components of nanoemulgel and it gives texture to the formulation. These are actually cross-linking agents. Examples Natural- agar, tragacanth, xanthan gum, guar gum etc Synthetic and semi-

synthetic gums like Carbopol, Poloxamer, HPMC (cellulose derivatives) etc. are some of the gelling agents used in nanoemulgel preparation.

Preservatives

These are the chemical agents used to protect the formulation by the microbial attack and hence increase the shelf life. Phenoxyethanol, Benzalkonium chloride, Benzoic acid, Methyl paraben and Propyl paraben are generally used preservatives in the formulation of nanoemulsion [17].

Antioxidants

These are the chemical agents used in the formulation to protect the various components from oxidation. Ascorbyl palmitate, and Butylated hydroxyl anisole are most preferred antioxidants in topical nanolipoidal preparation [18].

Characterization

Zeta Potential

As nanoemulgel is basically a composition of nanosized emulsion droplets along with a gelling agent, the formulation can exhibit an electrical charge due to the involvement of various types of surface-active agents. The nature and characteristics of electrical charge on the surface of emulsified droplets are very crucial for the stability of entire dosage form [19]. Zeta potential is the measurement of electrical charges at the shear plane. The shear plane is the distance from the globule surface where the various counter ions are attached to the globules in the electrical field.

Droplet Size Measurement

Droplet size measurement is the most important characterization of nanoemulgel preparation. In any nanolipoidal formulation, size of droplets/particles can be directly related to the stability, drug release as well as in vivo performance of dosage form and hence, resembles a significant property for the analysis [20]. In nanoemulgel, the size of droplets can range from 5 to 500nm. Generally, Dynamic Light Scattering (DLS) method is used for the determination of droplet size.

Poly Dispersity Index (PDI)

PDI is the most important characterization of nanoemulgel preparation. In any nano lipoidal formulation, size of droplets/particles can be directly related to the stability, drug release as well as in vivo performance of dosage form and hence, resembles a significant property for the analysis . In nanoemulgel, the size of droplets can range from 5 to 500nm. Poly dispersity index or particle size distribution reflects the size distribution of droplet diameter and it can be measured by analyzing the intensity of scattered light as a function of angle between the incident and scattered beam which follows the light scattering theory [21].

Rheological Characterizations

It has been discussed that a nanoemulgel contains oil, surfactants and a gelling agent as fabricating components. A minute change in the physicochemical properties of formulation components can greatly affect the rheological properties of a dosage form such as viscosity and flowability. The change in viscosity can further affect the stability factors as well as drug release and other biological functions. Taking these factors into consideration, it is very essential to understand the rheological properties of nanoemulgel. Viscosity measurement can be carried out with different kinds of viscometers [22, 23].

Mucoadhesive Property

Usually, nanoemulgel preparations are delivered through mucosal layer such as nasal mucosa. In this kind of delivery system, it is important to analyze the mucoadhesive strength. The mucoadhesive strength can be defined as the force required for detaching the dosage form from the nasal mucosal tissue. Here for this test, a modified method can be used [24, 25]. In this method, nasal tissue of sheep can be used. One can obtain the tissue from a local slaughter house. The fresh tissue should be used just after separation. In the experimental procedure, a precalibrated

force displacement transducer is required. Here, the exposed mucosal part of the sheep nasal mucosa is fixed to the upper probe with the help of a cyanoacrylate adhesive, then the probe needs to be attached to the transducer for obtaining the electronic data indicating the force .

Measurement of pH

Various Topical formulations have pH in range of 5-6 measured by using pH meter. For testing, 1g of gel is taken and it is dissolved in 10ml of water. PH of each formulation is done on triplicate order to avoid error [26].

Swelling Index

1 gm. of prepared topical nano emulgel is taken on a porous aluminium foil which is then placed on 10 ml of 0.1 N NaOH solution. Samples are removed time to time and weight is noted till no further change is observed.

Measurement of Bio adhesive strength

Bio adhesive strength is measured by placing one glass slide separated from two other glassed slides on each arm of apparatus. Single slide is used for adding weight. Accurately weighed 1gm of nano emulgel is placed between the slides containing rat skin pieces (hairless). Weight is placed on single glass slide that creates some pressure to remove the sandwich of two slides. Addition of extra weight is placed as 200 mg/ min until the detachment of the skin surface is observed. Required weight to detach the nano emulgel from skin give bio adhesive strength.

Accelerated stability studies

As given in ICH guidelines, the formulations are stored in oven at 37±2°C, 45±2°C and 60±2°C differently for 3 months. Drug content is analyzed for every two week by suitable analytical techniques like UV. Measurement of stability studies is based on change in pH of gel or drug degradation [27].

Determination of % drug content

1 gm. of prepared nano emulgel is taken and it is mixed with 25 ml of methanol. This solution is sonicated for 30 min. Drug content of the solution was calculated using the suitable analytical methods like UV etc.

Spread ability

It can be measured by using Slip and Drag method. Here 2gm of nanoemulgel is placed on lower ground slide which is fixed with wooden block and sandwich is prepared by other glass slide having similar size which is attached with hook having 500 mg weight placed on it. After 5 mins extra weight was placed on pan connected with second slide. The time taken to cover 5 cm distance for upper slide was noted.

Skin irritation test

0.25 gm. prepared nano emulgel is applied on the skin of rabbit. After 24 hr of application rabbit skin was wiped and cleaned, change in color of skin or undesirable change in morphology is observed and noted.

***In-vitro* Diffusion studies**

Franz diffusion cell is used to perform diffusion study of prepared nanoemulgel. A cellophane membrane is used for study and 0.5g of sample applied on membrane and diffusion is carried out for 8 hr at 37±1°C using phosphate buffer (pH 7.4). At time interval of 1 hr, 1 ml sample is collected and replaced with new buffer solution. Collected samples are analyzed by using suitable analytical method like UV etc. [28]

CONCLUSION

Experimental studies have demonstrated that nanoemulgel formulations represent a promising alternative to conventional drug delivery systems, particularly for BCS Class II and IV drugs across various pharmacological categories. The method of formulation and the selection of components play crucial roles in determining both the

stability and therapeutic efficacy of these dosage forms.However, since nanoemulgels consist of multiple components—including different types of surfactants careful attention must be given to their selection and concentration. Excessive use of surfactants can lead to mild or even severe toxicological effects, making their optimization a critical aspect of formulation development. Looking ahead, nanomulsion gel based formulations hold great potential as a reliable and effective approach for the delivery of hydrophobic drugs**.** Many therapeutic agents used for treating skin disorders are lipophilic in nature, and incorporating such drugs into the oil phase of a nanoemulsion followed by integration with a gel base offers an efficient strategy for enhancing their solubility, stability, and targeted topical delivery.

ABSTRACT

Employee training and development are a given in every contemporary organizational structure. Undoubtedly, it is an essential instrument for any organization to survive. This study sought to evaluate the quality of development and training offered by ITES organizations in Bengaluru. The selected research design is primarily descriptive in nature. Employees of ITES firms make up the study's universe. This study use the convenient sampling method. Primary information gathered via a standardized questionnaire from 100 ITES company employees and Secondary data were gathered from papers, journals, websites, and other sources of prior study. ANOVA,'t' test, and simple percentage analysis are employed in data analysis. Age, gender, and experience all had a good impact on training and growth, according to this study.

Keywords: - Training, Development, Employees, Effectiveness, Bangalore

INTRODUCTION

The nature of business varies greatly in the modern world. In order to adapt to these changes and use new technology, training is a crucial tool for any firm. Effective training has an impact on human interactions, productivity, and the adoption of new technology and knowledge updates, among other things. In order to train their staff more effectively and decrease industrial accidents, the majority of firms these days spend more money on training and development programs. According to modern management theory, an organization's human capital can give it a competitive advantage. This benefit can only last as long as the workforce is skilled and competent. Training and development make sure that human capital has the necessary skills and knowledge. As a result, the role of training and development is valued highly in any organization. In India, conducting a training program to improve a company's human resources is given significant weight.

Development is defined as

Memoria states that "development encompasses not only activities that enhance job performance but also those that foster personality development, support people in their journey towards maturity, and help them realize their full potential so they become not just better employees but better men and women." Yoder states that "Development is an inclusive process that involves managers and individual employees. "In addition to providing chances for skill acquisition, it fosters ongoing personal development by fostering the discovery and development of fundamental attitudes and abilities.

ITES- Information Technology Enabled Services

India is known as the world's back office because of its Information Technology-enabled Services (ITES) industry. The information technology sector's income increased from 1.2% of GDP in 1997–1998 to an anticipated 5.8% in 2008–2009, according to the National Association of Software and Service Companies (NASSCOM), the leading organization for software services in India. Indian IT-BPO saw a 12% growth in 2008–09, with total revenue of US$ 71.7 billion. Exports of software and services, which comprise BPO, engineering services, R&D, software products, and IT services, totaled US$ 47 billion, or about 66% of the total revenue from IT and BPO. Over the past ten years, ITES has expanded its range of services from basic data entry activities to more complicated procedures involving rule-based decision making and even research services needing well-informed individual judgment. These days, it provides services like de-sign outsourcing, games process outsourcing, legal process outsourcing, and knowledge process outsourcing (KPO), among others.

India's BPO Sector: A Report

An Analysis of the Indian BPO Sector The term "business process outsourcing" (BPO) is used to describe outsourcing in all contexts. In order to set itself apart, a BPO either implements new technology or uses already-existing technology in novel ways to enhance processes. Business process outsourcing, or BPO, is the transfer of ownership, administration, and management of one or more IT-intensive business processes to an outside vendor. The vendor then oversees the chosen process in accordance with predetermined and quantifiable performance standards. One of the areas of the information technology enabled services (ITES) market with the quickest rate of growth is business process outsourcing, or BPO.

- ✓ A few of the driving forces for the growth of BPO are as follows:
- ✓ Cost Advantage Factor
- ✓ Efficiency of Scale
- ✓ Reduced Business Risk
- ✓ Improvement in Utilization and Superior Competency

In general, outsourcing is described as: An organization hiring another company to run and oversee one or more of

its business operations. Indian BPO sectors provide services in response to societal demands. Here are some examples of the Indian BPO industries services we provide to multinational corporations (MNCs) and Indian corporate companies.

- ✓ The services offered include customer support,
- ✓ technical support,
- ✓ telemarketing, and
- ✓ Employee IT help desk.
- ✓ Data Entry / Data Processing Services
- ✓ Insurance Processing

Notable BPO businesses with headquarters in Chennai include Sutherland, Allsec, and HCL Technologies**.**

Software industries in India

The software industry in India began to take off in the late 1990s. At that time, the majority of Indian software companies primarily provided a small range of software services, like banking and engineering software. The Y2K crisis, which demanded a huge number of qualified workers to meet the enormous need for database correction in order to deal with the start of the new millennium, marked the beginning of the business software boom. In recent years, there has been a shift in the characteristics of Indian IT services, which may be attributed to both market dynamics and advancements in the value chain. Most US businesses would not have even considered outsourcing part of their IT projects to outside suppliers ten years ago. Ten years later, the vast majority of US businesses still rely on the expert skills of Indian software engineers, whether directly from people hired or through large, medium, or small businesses. The Indian IT software and services sector is expanding steadily in spite of the global economic downturn. The field of software development is not limited to a few Indian towns. Bangalore, Hyderabad, Mumbai, Pune, Chennai, Calcutta, Delhi-Noida Gurgaon, Vadodara, Bhubaneswar, Ahmedabad, Goa, Chandigarh, and Trivandrum are just a few of the rapidly growing software development centers. Modern software facilities and a big number of foreign vendors may be found in all of these locations. India's widely available technical labor force is its most valuable resource. India is one of the three nations that has produced its own supercomputers. The USA and Japan are the other two. India is one of six nations that launch satellites, including ones for Belgium and Germany. One of the biggest domestic satellite communication systems in the world is India's INSAT. India is among the top ten countries in the world with the third largest telecommunications network among rising economies.

Moving up the value chain and concentrating on completed goods and solutions rather than just skill sets and resumes will help us become and become a worldwide leader in the IT industry. Instead of providing our services as raw materials, we must be able to package them as goods. We must be able to identify our strengths, build on them, and address our flaws.

Tamil Nadu's Software Sector

Of all the states in South India, Karnataka is one of the top states for the expansion of ITES and software. The government of Karnataka and STPI have placed greater emphasis on the development of this software and the ITES industry. The IT industry in Karnataka is strong due to a number of factors. Among these elements are

- ✓ The greatest reservoir of highly skilled and technically proficient IT personnel in India - Of the 136,000 engineering graduates that graduate each year from 355 Karnataka engineering colleges, 37% have a background in computer science, information technology, or electronics and communication.
- ✓ Offering a wide range of services from support / data processing to sophisticated software systems, etc., Karnataka has a significant comparative advantage due to its vast skilled human resource base, which is much lower than that of developed countries.
- ✓ 28 active IT SEZs in Karnataka. Rich experience working with large, international firms and enjoying great repute. Expertise on a wide range of platforms.
- ✓ There are now 234 planned IT parks in Tamil Nadu, totaling 131 million square feet of built-up area.

- ✓ There are 1683 software exporting units that employ around 285,000 software experts and have an export performance of Rs. 36680 Crores (US $8120 million).
- ✓ With a growth rate of 29.04%, Karnataka has the highest software export rate in India.

Chennai boasts the highest bandwidth in India, measuring 13.52 terabits per second, thanks to two submerged OFC cables that connect the city to the global network. Software and services exports, which include BPO, engineering, R&D, and software product exports, totaled US$ 47 billion in FY 2008–09, accounting for approximately 78% of the US$ 59.6 billion in software and services income, according to NASSCOM. The domestic market in India has grown significantly in strength as well, thanks to advancements in technology and penetration depth in the country's IT infrastructure. One of the bright spots of the Indian economy, the information technology sector is still expanding quickly and holds great potential. A McKinsey research prepared for NASSCOM projects that by 2020, the export-oriented sector of the Indian economy will generate $175 billion in revenue. By 2020, the domestic component will generate $50 billion in income.

Previous research and studies

According to Ogunu (2002), there were sufficient facilities for staff training to enable management staff to receive effective training; the management staff's training program was pertinent to the tasks they carried out; and the staff's training program did, in fact, enhance their effectiveness and performance at work. According to Hunt and Baruch (2003), some organizations devote a significant amount of time and resources to complex training programs intended to enhance the so-called soft skills of management. According to Gopal (2008), training evaluation is merely the beginning of the training function rather than its precise conclusion. According to Nagar (2009), the respondent organizations' training programs are typically effective in terms of course length, library resources, trainers, computer-assisted instruction, and infrastructure.

Based on demo-graphic characters, Ramachandran (2010) found that employees' perceptions of the efficacy of the training program varied. Additionally, it is implied that the organization's personnel' education and experience play a major role in selecting the training program. According to Saharan (2011), in order to maximize the benefits of training, the majority of organizations solicit employee input on its efficacy. In their never-ending quest for a competitive advantage, businesses hold the view that more intelligent and skilled employees increase the likelihood of success.

According to Raja Abdul Ghafoor Khan et al. (2011), organizational performance is positively impacted by training and development, on-the-job training, training design, and delivery style. All of these factors have a substantial impact on organizational performance. It implies that it improves the performance of the organization as a whole. According to Henry Ongori and Jennifer Chishamiso Nzonzo (2011), employee development and training boosts competitiveness and organizational success.

According to research by Rohan Sing and Madhumita Mohanty (2012), productivity is significantly impacted by training. But its importance is diminished by other strong market pressures. According to Francis Boadu et al. (2014), managers and staff encountered unusual issues throughout training and development activities. Employees had concerns about the amount of time allocated to various training and development programs, while management grumbled about funding. Ayo-dele Ekundayo (2015) discovered a strong positive correlation between employee job security and training/development, as well as a large positive correlation between workers' productivity.

Methodology of the Study

The study used primary and secondary data that was conducted at KSFC. Primary Data: Through in-person interviews, a methodical, pre-tested questionnaire was constructed. Secondary Data: Articles, Concerned Books,

Magazines, Newspapers, Office Reports, Annual Reports of KSFC Journals, and information from the official website comprise this data.

RESEARCH METHODOLOGY

The selected study design is descriptive in character. The study's target population consists of the workers at Bangalore based ITES companies. To perform the research, a sample size of 100 employees was used. Convenient sampling was used to choose the respondents. A structured interview schedule was employed to gather primary data. Secondary data came from published journals, periodicals, websites, and online pieces, as well as past study projects. The statistical package for social sciences, or SPSS, uses three methods for data analysis: t-test, analysis of variance (ANOVA), and simple percentage analysis.

Period of the Study:

Data is gathered for the current study during a five-year period, or 2009–2013.The following are the training and growth opportunities that head office offers to its staff:

Analysis and Interpretation

This table indicates that forty-four percent of the participants are older than forty, while fifteen percent are between the ages of thirty and forty. Male respondents make up 74% of the sample, while female respondents make up 26%. Twelve percent of respondents have less than two years' experience in the current company, while 49 percent of respondents have more than five years' experience. Twenty percent of respondents had five to ten years of experience, and fifty percent have more than ten years of experience overall.

Classification based on Study Factors

As can be seen from the above table, 42% of respondents strongly disagree that training gave them opportunity to learn and grow, whereas 6% of respondents agree. A total of 10% of respondents and 39% of respondents strongly agree that training objectives fit their work needs, respectively. Seven percent of respondents strongly disagree that training needs are recognized through a formal performance appraisal method, whereas thirty-two percent of respondents strongly agree that such needs are identified. Ten percent of respondents had a neutral opinion regarding sending someone for training, while twenty-four percent of respondents strongly disagreed that it was done for promotion. Ten percent of respondents strongly disagree that the training's aims are to comprehend various managerial functions, whereas thirty-one percent of respondents strongly agree with this statement. 39 percent of respondents concur that the training needs that have been identified are reasonable and grounded in corporate strategy, whereas nine percent of respondents strongly disagree with this assertion. 10% of respondents strongly disagree that efficiency is important for handling difficulties affecting human connections, whereas 40% of respondents think that efficiency is important. Thirty percent of the respondents strongly concur that decision-making abilities have improved as a result of training, whereas nine percent strongly disagree. Five percent of respondents disagree that they feel more confident and capable of acting as a leader, while 42% of respondents believe that they experience these qualities. Seven percent of respondents dispute that there has been an improvement in the interaction between associates and coworkers, while thirty-five percent of respondents agree. Respondents feel more prepared to handle unforeseen situations, according to 42% of respondents who strongly agree with this statement and 5% of respondents who strongly disagree.

Training and development based on age

H0: Opinions on training and development do not significantly differ based on the age of employees.

The ANOVA table mentioned above is utilized to examine the disparity in viewpoints regarding age and training and growth. It demonstrates how employee age affects the opportunity for learning and development, the identification of training needs, and the effectiveness of handling human relations issues. P-values indicate significance. As a result, the hypothesis is not accepted. The types of training and development offered depend on

the age of the workforce. Employees in the middle age group differ from other groups in terms of training opportunities for learning and development, identifying training needs, and effectiveness in resolving human relations issues.

Training and development based on present experience

H_0: There is no significant difference of opinion towards training & development depending on employees' present experience

To assess the differences in opinions regarding training and growth and current experience, the ANOVA table above is utilized. It demonstrates how training objectives are tailored to the needs of the workplace, how training is sent for promotional purposes, and how the training's goal is to help employees comprehend how management duties alter depending on their current experience. At one percent, the P-values are significant. As a result, the hypothesis is not accepted. Depending on the employees' current experience, there are different levels of training and development. Employees with more experience in the current organization are sent for training for promotional purposes and are separated into groups based on training objectives that meet job needs. Employees with less experience in the current organization are different from other groups in that their training objectives are to comprehend various managerial functions.

Training and development based on overall experience

H_0: There is no significant difference of opinion towards training & development depending on employees' overall experience

To examine the differences in opinions on training and growth and overall experience, the aforementioned ANOVA table is utilized. It demonstrates that the specified training needs are reasonable and grounded in business strategy; additionally, training has enhanced decision-making abilities and made employees feel more equipped and confident, with these differences depending on the employees' overall experience. P-values indicate significance. As a result, the hypothesis is rejected. Depending on the employees' overall experience, different training and development programs are offered. Higher experienced workers differ from other groups in that their training demands are realistic, grounded in corporate strategy, and equipped with demonstrated decision-making skills. Compared to other categories, less experienced workers feel more assured and qualified to take on leadership roles.

Training and development based on gender

H_0: There is no significant difference of opinion towards training and development based on gender.

The t-test is used to investigate the aforementioned hypothesis. The computed p-values from the test are determined to be significant at one percent. As a result, the proposed hypothesis is rejected. It is implied that employee gender has a substantial impact on differences in training and development.

RESULTS AND DISCUSSION

It is discovered that the company offers development and training more effectively. The majority of employees concurred that training and development components are important, and that training yields positive results. Employees in the middle age group differ from other groups in terms of training opportunities for learning and development, identifying training needs, and effectiveness in resolving interpersonal conflicts. Employees with more experience in the organization are sent for training for promotional purposes and are separated from other groups based on training objectives that suit job needs. The training objectives for low-experience employees in the current organization are distinct from those of other groups in that they focus on understanding various management functions. In general, more seasoned workers differ from other groups in that their training needs are reasonable, founded on company strategy, and have demonstrated the ability to make sound decisions. In general, less experienced workers feel more confident and more qualified to take on leadership roles than other categories. It is assumed that there are major differences in training and development depending on the gender of the personnel. Additionally, it is advised that the business implement new technologies to teach its important staff members with

the assistance of qualified faculty members. The organization should also give more facilities to meet the needs of its staff members with regard to training and development. Only when the training session is more comfortable will it be effective.

FINDINGS, SUGGESTIONS AND CONCLUSION

Finding:-

1) According to employee feedback, regular training sessions will decrease errors in work and boost confidence in handling issues that arise while working.
2) They also think that hiring outside specialists for training programs could help them learn new skills and approaches to performing their duties.
3) The staff believes that after receiving training and growth, they ought to be transferred to different states to observe how well they function at work.
4) Employee growth and development, increased motivation, and increased production were all aided by training programs.

Suggestion:

- ✓ Shorter training sessions, like those lasting a week or fifteen days, are necessary because they bore personnel. Effective training can therefore only be given for a limited number of days, up to two or three.
- ✓ Companies need to support female employees' access to training on par with that of male employees.
- ✓ All departments, for all personnel levels, should require training and development. in order for everyone to advance intellectually and increase error-free work performance.

CONCLUSION

One tool used to communicate top management plans through training and development is performance appraisal. It looks at what workers are expected to do as well as how they perform for the company. Training and development are essential for managers at all levels, from the top to the bottom, and performance appraisal techniques can be used to assess their work. Without a doubt, KSFC workers' job performance is significantly impacted by their training and development. Employee knowledge, competence, and motivation increase as a result of training and development initiatives. Organizations must implement development and training in their wide range of operations to fulfill their mission and achieve organizational goals in order to meet their overall objectives. Employers must take this important activity seriously and use all of the funds allotted to them for employee training and development in order to improve employee performance and foster harmonious working relationships. This research used primary and secondary data collected from employees to evaluate the efficacy of training and development programs in ITES organizations. The study's conclusions show that in addition to the company offering excellent training and development opportunities to its staff, factors such as age, gender, and experience also have an impact on training and development.

ABSTRACT

A sensitive and precise RP-HPLC (reversed-phase high-pressure liquid chromatography) procedure was effectively developed and confirmed in the simultaneous determination of emtricitabine and tenofovira disoproxil fumarate in both raw materials and final pharmaceutical product. A Phenomenex C18 column was used to separate, with a mobile phase of acetonitrile/phosphate buffer (pH 6.8) in a 1:1 (50:50) ratio, to give the best resolution. The analytes were eluted at a rate of 1.0 mL/min and were detected with a UV-Vis detector at 260 nm wavelength. The developed method showed strong linearity over the ranges of 10–50 µg/mL for emtricitabine and 15–75 µg/mL for tenofovir disoproxil fumarate. Emtricitabine and tenofovir disoproxil fumarate eluted at around 2.4 and 4.3 minutes, respectively. Validation was carried out following ICH guidelines, assessing various parameters including accuracy, precision, specificity, and method robustness. The developed method proved suitable for conventional analysis of both bulk substances and tablet formulations, with no interference detected from common excipients. High recovery rates nearing 100% further confirmed the consistency and reliability of the technique for pharmaceutical analysis.

Keywords: RP-HPLC, Emtricitabine, Tenofovir disoproxil fumarate, Validation, Retention time, Phenomenex C_{18} column.

INTRODUCTION

Emtricitabine and tenofovir are antiretroviral agents that play a pivotal role in the managing HIV infections. Both medications are classified as nucleoside/nucleotide reverse transcriptase inhibitors (NRTIs), which inhibit virus replication by the reverse transcriptase enzyme. Emtricitabine, a cytidine analogue, and tenofovir, an adenosine monophosphate analogue, are often co-formulated due to their complementary pharmacokinetic profiles and synergistic antiviral activity. The fixed-dose combination of emtricitabine and tenofovir [1] has been widely adopted in antiretroviral therapy (ART) regimens, particularly as part of first-line treatment strategies recommended by international guidelines. Additionally, their use extends to significantly reduce the HIV acquisition in larger risk-prone populations. Despite their proven efficacy and favourable safety profile, concerns regarding long-term toxicity, resistance development, and adherence challenges remain areas of active research and clinical interest.

A thorough survey of the literature showed, various practices are possible for the simultaneous detection of emtricitabine and tenofovir drugs, including UV, HPLC, HPTLC, RP-UPLC [1] methods. The scope of this research was to propose a new method that is unique, specific, and rapid for the concurrent evaluation of drugs with a shorter retention time and a new solvent combination using phosphate buffer along with an organic solvent. Developed method[2] was validated according to the ICH regulations [2]. Overall, the proposed RP-HPLC method provides a robust and valid approach for estimation of Tenofovir and Emtricitabine, contributing to the field of pharmaceutical analysis and ensuring the quality assurance of medications for HIV/AIDS treatment.

MATERIALS AND METHODS

Standard samples of emtricitabine and tenofovir disoproxil fumarate were procured from Aurobindo Laboratories. HPLC grade water, HPLC grade dihydrogen phosphate and acetonitrile were purchased and used to prepare mobile phase and diluents. Mobile phase was sonicated before use. Travuda tablets containing emtricitabine 200 mg and tenofovir 300 mg were brought from the local market. Chromatographic separation was carried on a Schimadzu LC-20 AT series HPLC system equipped with a C-18 Phenomenex column (250*4.6mm, 5µm) with a binary pump and an SPD-20A Prominence UV/VIS detector [3,4]. The sample was injected into the column using a Rheodyne 7725 injector valve through a 20µL loop. Initially trails were carried out by using different solvents such as trichloroacetic acid buffer, acetate buffer, methanol and water where peak splitting, no proper peak shape, no better elution was observed hence the below optimized conditions[5] were selected for better separation and analysis of drugs.

Optimized Chromatographic Parameters:

- Stationary Phase: Phenomenex C18 column, dimensions (4.6 × 250 mm, particle size 5 µm)
- Column Temperature: Maintained at 25 °C
- Liquid Phase Flow Rate[4]: Set to 1.0 mL per minute
- Sample Injection Volume: 20 µL per run
- UV Detection Wavelength: 260 nm
- Total Analysis Time: 10 minutes
- Sample Diluent: Same as the Solvent phase
- Liquid phase: Acetonitrile: Phosphate buffer of pH 6.8 (50:50v/v).
- Retention time: 2.481 (Emtricitabine) 4.329 (Tenofovir)

Buffer Preparation [5]

Measured amounts of potassium dihydrogen phosphate and sodium dihydrogen phosphate were dissolved in HPLC-grade water. pH of the buffer solution was carefully adjusted to 6.8 using an appropriate base. After pH adjustment, the solution was subjected to ultrasonication to ensure thorough mixing and removal of any dissolved gases. The resulting buffer was employed as the mobile phase in the chromatographic procedure.

Preparation of Mobile phase [6]

Mix HPLC grade acetonitrile and prepared phosphate buffer solution of pH 6.8 in a 1:1 ratio, filter the resulting solution, and ultrasonicate it, the resulting solution is used as the mobile phase.

Preparation of standard stock solution [6]

The primary stock solution of emtricitabine was prepared by dissolving approximately 20mg of emtricitabine in few mL of diluents, sonicating for approximately 15 minutes, and making up to the final 10 mL mark to obtain 2000 µg/mL of emtricitabine. From this solution working standard solution and further dilutions are prepared ranging from 10-50 µg/mL. Tenofovir stock solution was prepared in a similar manner by dissolving approximately 30mg of tenofovir in few mL of diluents, sonicating for approximately 15 minutes, and making up to the final mark to obtain 3000 µg/mL tenofovir. From this solution working standard solution and further dilutions are prepared in the concentration range of 25-85 µg/mL.

Sample Injection

The degassed solvent was loaded in the reservoir followed by purging. The liquid phase was run at the desired flow rate until a stable baseline was obtained. The sample mixture[6] was sonicated and then injected into the port (Rheodyne injector port) using a syringe. Finally, the column was thoroughly washed with the mobile phase for about 30 minutes after the analysis of sample mixture.

Validation of the Developed RP-HPLC Method

Specificity [7]

The specificity of the analytical method reflects its ability to accurately detect and quantify the target analyte in the presence of other potentially interfering substances, such as excipients or impurities. Experimental findings indicate that the developed method shows no detectable interference from other components within the pharmaceutical formulation, thereby establishing its suitability for selective analysis.

Linearity [7]

It is one of the parameters which gives a direct relationship between the analyte concentration and the method response. The calibration curve for the injected samples into the column showed linear relationship for peak area Vs concentration ranging from 10 to 50 µg/ml for emtricitabine and 15 to 75 µg/ml for tenofovir and according to the ICH recommendation it found to be linear.

Precision [8]

It ensures the reliability and reproducibility of the analytical method. The RSD for intraday and interday precision did not exceed 2.0% for the reference drugs Emtricitabine and Tenofovir. The low RSD values indicate the repetition and reproducibility of the system.

Accuracy [8]

It refers to the closeness of the method response to the accepted values ensuring quantification of the analyte in the sample. It was determined by spiking the standard drug with known amounts of analyte prepared at different concentration levels such as 80,100,120%. The %RSD of the recovered amounts should not exceed 2%. suggesting that the developed method is accurate.

Ruggedness

The degree of reproducibility of the test result under varied conditions such as different laboratories, analyst, instruments and environmental conditions The %RSD for the results obtained from different analysts was within the specified range. and hence the developed method was found to be reliable.

Robustness

The ability of an analytical method to remain unaffected by small deliberate variations[8] in the method parameters. The %RSD of both the components was found to be within 2.0%.

Limit of detection and Limit of quantification [9]

The limit of detection (LOD) and limit of quantitation (LOQ) define the smallest amounts of the analyte that can be detected and accurately measured, respectively, under the established experimental conditions. Following ICH guidelines, the method exhibited precision with relative standard deviation (RSD) values below 2% at the LOQ level, indicating reliable sensitivity and consistent quantification at low concentrations.

DISCUSSION

A reverse-phase high-performance liquid chromatography (RP-HPLC)[10] method has been successfully developed and validated for the simultaneous estimation of emtricitabine and tenofovir, demonstrating high levels of accuracy, precision, specificity, and reliability[10]. Compared to earlier techniques, this method offers significant advantages, including a shorter analysis time, cost-effective and easily accessible mobile phase components, UV-Vis detection, and improved peak separation[11]. The reduced run time enhances throughput, making it ideal for routine quality control of formulations containing these active ingredients. Additionally, the method effectively quantifies both drugs in their bulk and dosage forms without interference. The validation results[12], aligned with International Conference on Harmonisation (ICH) guidelines[12], further confirm its selectivity and robustness[12].

ACKNOWLEDGEMENTS

The Authors extend their gratitude to the management of Aditya Educational Institutions for continuous support and encouragement during the research study.

ABSTRACT

An intracellular iron dependent mechanism of cell death known as Ferroptosis that is characterised by the accumulation of lipid peroxides. Because of high iron metabolism and oxygen radical induced stress of cancer cells, it has become an emerging target for cancer treatment. The interaction of lipid peroxides, anti-oxidant defences and iron metabolism controls the process. Recent research discovered that the ferroptosis is a promising mechanism for selective killing of cancer cell particularly for which are noncompliance to conventional treatments including chemotherapy, radiotherapy and immune based therapy. Cancer cells frequently alter the metabolic profiles, including enhanced iron levels and increased oxidative stress, which make them highly vulnerable to ferroptosis. This vulnerability provides a novel therapeutic window for targeting resistant and aggressive tumour types. The current review deals with

the various mechanisms, role of ferroptosis and resistance mechanisms of cancer along with the challenges and future aspects**.**

Keywords: Ferroptosis, parthanatos, non-apoptotic programmed cell death, lipid peroxidation pathway, iron metabolism, antioxidant defences.

INTRODUCTION

Ferroptosis different cell death mechanism that is completely different from necrosis, necroptosis, parthanatos or the other similar cell death mechanism. It is an iron induced oxidative forms of non-apoptotic programmed cell death. Ferroptosis is first detected as an innovative form of cell loss by Dixon in the year 2012[1]. Ferroptosis a systematic cell demise that is influenced by elevated levels of cellular iron ions and toxic lipid-based ROS (Reactive oxygen species), regulated by various biochemical networks [2]. He found that RAS (Rat sarcoma) driven cancer molecule Erastin induces specialized cell death mechanism designated as Ferroptosis [3]. In cancer, certain oncogenic pathways can influence the critical regulatory elements of ferroptosis and trigger ferroptotic death in cancer cells. Prevailing cancer therapies with restricted clinical effectiveness often face challenges in terminating cancer cells due to therapeutic resistance or reduced sensitivity. on the other hand, growing research suggests that activating ferroptosis can greatly enhance the effectiveness of removing cancer cells, emphasizing ferroptosis as a vital method in cancer treatment [4]. In modern times, ferroptosis has served to impact its contribution in various diseases, including neurodegenerative conditions and cancers such as liver, breast, and lung cancer. It functions not only as a anticancer gene but also has oncogenic properties. Importantly, cancer cells that are tolerant to usual therapy or prone to metastasis are more liable to ferroptosis [5]. Ferroptosis is monitored by several cellular mechanisms including iron metabolism, mitochondrial functions, and amino acid processes, lipid peroxidation, and others. Moreover, disruptions in redox balance are a contributing factor to various diseases [6]. This review provides a comprehensive overview of the mechanisms of ferroptosis and its role in cancer.

Mechanisms of Ferroptosis

As studies into ferroptosis's mechanics and relationships to cellular metabolic pathways continue, it has become a major focus of interest. The creation and degradation of lipid reactive oxygen species are incompatible, which triggers this mode of cell death. Increased lipid ROS levels cause oxidative cell damage, which leads to ferroptosis [7]. These evaluations have presented a strong conceptual basis for comprehending how ferroptosis begins, which can be primarily classified separated into three main pathways: the iron metabolism, the lipid metabolism, and the GPX4 (Glutathione peroxidase 4) -regulated mechanism [8].

Compliance with the GPx 4 regulatory pathway

GPX4belongs to the GPx (Glutathione peroxidase) family and has the ability to generate self-generated antioxidant activity in cells to reduce lipid derived ROS levels, hence reducing cellular ferroptosis [9]. The nephrotic core is modulated by GPX4, which makes it possible to assess the occurrence of ferroptosis within cells [10]. The cystine-GSH-GPX4 axis functions as an essential pathway to counteract ferroptosis in mammals. Upon penetrating the cell, cystine (Cys2) may undergo oxidation and get converted into cysteine (Cys). Glutathione (GSH) is primary antioxidant in ferroptosis and is produced by using cystine, glycine and glutamic acid, Glutamate cysteine ligase and glutathione synthetase are employed as catalysts in that procedure. Glutathione (GSH) is a cellular molecule primarily available in its lower oxidised form, granting its ability to competently capture ROS and defends the oxidative damage of the cells. Although, GSH gets oxidized and converted into oxidized glutathione disulfide (GSSG) when it is interacted with ROS an oxidising agent. Using glutathione disulfide reductase (GSR) and a few electrons generated by NADPH/H+, oxidative glutathione (GSSG) is converted to GSH, resulting in a cyclic process.

GSH collaborates with GPX4, which is essential for protecting against ferroptosis, to catalyze the reduction process of hydrogen peroxide and organic hydrogen peroxides to water or the equivalent alcohols [11]. The production of corresponding alcohols (PLOHs) results from an increase in any phospholipid hydroperoxides (PLOOHs) produced inside the cell are reduced by GPX4. GPX4 inhibition can cause ferroptotic cell death right away. Ferroptosis is also caused by blocking the production of GSH, a cofactor of GPX4. Cysteine, a crucial intracellular antioxidant, can regulate the amino acids necessary for the synthesis of GSH. Because xCT (cystine/glutamate anti-porter) can regulate the cellular intake of cystine, which can be reduced to cysteine affecting GSH synthesis, inhibiting the xCT system is crucial to improving ferroptosis [12]. Glutathione (GSH), an antioxidant, is used by cells to neutralize PLOOHs and stop the ferroptosis process. GPX4 functions as a selenium protein, and a required REDOX enzyme found in human cells. GPX4 is responsible for the body's conversion of cholesterol peroxides and phospholipids to their corresponding alcohols. The two electrons and selenium residues that are typically needed for this reaction are provided by glutathione [13]. Ras-selective lethal 3 (RSL3) neutralizes PLOOHs mainly through GPX4, which causes ferroptosis. Ferroptosis development is either directly or indirectly associated with GSH depletion-induced inhibition of GPX4.Erastin suppresses the synthesis of cysteine, a crucial component of GSH in cells, by blocking cystine generation, which in turn indirectly deactivates GPX4-RSL3.As a result, raising the PLOOH levels may cause extremely detrimental, irreversible membrane damage that ultimately leads to cell death [14]. Additionally, cancer cell ferroptosis may result from GPX4 inhibition. Consequently, a key function for the usual GPX4 mediated pathway in tumour biology [15].

Lipid metabolism pathway

The peroxidative damage of lipids is a crucial mechanism of ferroptosis, the metabolism in lipid peroxides is concerned as unique feature of ferroptosis. Lipid peroxidation can be enhanced by cellular intake of hydrogen atoms that are situated at the double bonds between two or more carbon atoms in the double membrane phospholipid layer, as an outcome phospholipid radical is formed at intermediate carbon position. The lipid bilayer components interact with o2 to fabricate phospholipid hydroperoxide radicals (PLOO), from which hydrogen atom is stealed from another PUFA (Polyunsaturated fatty acids), which ultimately leading the formation of PLOOH. Peroxidation of phospholipids present on the cell membrane to form PLOOH and its conversion into 4-hydroxynonenal or malondialdehyde can initiate the ferroptosis [16]. This PLOOH can aggregate via both enzymatic and nonenzymatic pathways. If the transformation process doesn't follow the steps outlined above, GPX4, phospholipid hydroperoxides, and free fatty acid radicals along with phospholipid peroxide radicals and alkoxy phospholipid radicals are not changed into their respective alcohols (PLOH). Instead of that, hydrogen radicles from the PUFA are eliminated followed by reaction with oxygen, thus results in the generation of PLOOHs [17]. From the above mechanism a variety of substances are formed from the lipid peroxidation leads to the membrane instability and permeabilization, which destroy the cellular envelope and gradually leads to cell demise.

Fenton reaction using iron as a catalyst is obtained as secondary reaction of non-enzymatic Lipid peroxidation, which produces free radicals of hydrogen or lipid. There were some focused PUFAs such as lipoxygenases (LOXs) that are independent hem dioxygenases can cause oxidative reactions; thus, it can also trigger ferroptosis [18]. Lipoxygenases (LOX) and cytochrome P450 oxidoreductase (POR) can also aid in the synthesis of PLOOH during enzymatic peroxidation of lipid molecule. Esterified and unbound PUFAs are deficient in oxygen to create PLOOH by direct catalysis by nonheme iron-containing enzymes known as LOXs [19]. One study found that cells are more susceptible to ferroptosis when LOX-5, LOX-12, and LOX-15 are overexpressed. The strong antioxidant properties of LOX inhibitors have also been demonstrated to protect cells from lipid peroxidation [20]. Thus, it is evident that the Fenton reaction and the fatty acid peroxidation process are significantly impacted by ferrous and ferric ion.

Metabolism pathway for iron

As we know that ferroptosis is an Iron dependent metabolic pathway which basically dependent on iron molecule that triggers the cell. A small pool known as the labile iron pool has elevated amounts of Fe2+, which is the unique nature of ferroptosis [21]. The labile iron pool (LIP) is coordinated with cellular iron homeostasis [22]. Fe^{3+} transferrin (TF) gets attaches to the transferrin receptors (TFR) present on the cell membrane and transferred to tissues. Two

molecules of Fe^{3+} can be transported by a single molecule of TF and attached with TFR and permeate the membrane through the process of endocytosis, dropped into the cytoplasm of the cell. These Divalent iron levels forms PLOOH as a result of Fenton reaction by redox mechanisms that are essential for formation. The sequence of peroxide chains is formed as a result of reaction of PLOOHs with Fe^{3+} that form PLO & PLOO. Iron used as a catalyst in ROS and lipid peroxidation that triggers the ferroptosis cell death [23]. The cellular iron levels are also an essential factor. Divalent metal transporter 1 (DMT1) is linked to ferrous concentration in cells and iron storage and utilization balance. Iron-regulatory proteins (IRP1 and IRP2) coordinate cellular homeostasis of iron, which can result in ferroptosis and intracellular activity of ferric molecules. In the existence of less stable cytoplasmic iron levels, some intracellular conditions enhance its responsiveness to ferroptosis [24].

Ferroptosis illuminated as an effective therapy for cancer because tumour cells require more iron levels in contrast with normal cells. So, change in iron metabolism pathway and inducing the cell death by making less stable iron molecule triggered ferroptosis as an effective therapy [25]. A novel therapy in cancer studies is chemo dynamic therapy (CDT). The mechanism of CDT contains nano enzymes which in turn helps in the stimulation of Fenton reactions in the cell to form hydroxyl radical. These radicals are lethal in nature which helps clearing the cancer cells [26].

Ferroptosis Function in Cancer.

Cell demise mediated by ferroptosis shows its vulnerability to the cancer treatment. It represents its role as a novel therapy for tumour suppression

Cancer cells Susceptibility to Ferroptosis.

Natural anticancer mechanism, ferroptosis that reduce tumours by interacting with several tumour suppressor genes, according to an increasing amount of evidence. Interestingly, it seems that cancer cells have a clear benefit in avoiding ferroptosis when they have mutations in particular oncogenes. Moreover, there has been a direct relationship between the development of tumours fuelled by cancer stem cells and followed by process of lymphatic metastasis in cancer [27]. Ferroptosis, an iron-dependent kind of controlled cell demise that has emerged as one of oncology's most promising developments, is brought on by the lethal accumulation of lipid peroxides on membranes within cells. In addition to preventing the growth of tumours, ferroptosis development can increase immunotherapy responses and overcome resistance to existing cancer treatments. We also develop ferroptosis [27]. The execution of biological functions and the survival of organisms depend on oxygen (02)-driven metabolism, which is accomplished by a series of redox processes. The essential component for catalysing these redox reactions that result in the production of ROS, which includes a variety of oxygen derivatives, including ferroptosis divers PLOOHs, is the transition metal iron. There is growing evidence that ferroptosis occurs in tumour biology [28].

Differences in ferroptosis sensitivity among cancer types.

Targeting ferroptosis is one possible approach to combat therapeutic tolerance and increase antineoplastic treatment efficacy. Numerous studies have shown that ferroptosis is essential for eliminating cancer cells and stopping their growth. Here, we present a possible clinical ferroptosis indicator along with a summary of the potential pathways of ferroptosis in different forms of cancer [29].

Lung cancer

Erastin initially caused cancer for lung cells with a mutation of K-ras to undergo ferroptosis [30]. According to the following data, erastin reduces GSH and inactivates GPXs, which enhances lung cancer cells susceptibility to cisplatin through ferroptosis [31].

Colorectal carcinoma

Due to TP53's (Tumor protein p53) transcription-independent suppression of activity of dipeptidyl-peptidase-4 (DDP4), Colorectal carcinoma was susceptible to ferroptosis [32]. Loss of P53 encourages DDP4 to aggregate at the

plasma membrane, which increases DDP4-dependent lipid peroxidation and ultimately results in ferroptotic cell death.

Gastric cancer

Ferroptosis in GC cells is stimulation of gastric cancer in response to erastin [33]. This effect can be reversed by liproxstatin-1 and ferrostatin-1. C-Myc (cellular Myc – myelocytomatosis oncogene) promotes ferroptosis by upregulating the usage of cysteine dioxygenase type 1. According to a different study, the CD44 variant (CD44v) prevents ROS-induced stress signalling, stabilises xCT at the selectively permeable barrier and boosts Cys2 intake for GSH production, giving GC cells resistance to ferroptosis [34,35].

Ovarian cancer

The tumour-initiating cells (TICs) of ovarian cancer cells overexpress TFR1 and have a reduced expression of the iron efflux pump FPN (Ferroportin), which results in severe iron overload and makes the cells vulnerable to ferroptosis [36]. Artesunate (ART) promotes ovarian tumour cells to exhibit ferroptosis by enhancing the cellular iron content [37].

Prostate adenocarcinoma

Erastin causes human prostate cancer cells that carry Ras to undergo ferroptosis. By preventing the formation of lipid ROS and iron absorption, the activation of heart shock factor 1 (HSF1)-reliant Ferroptosis in reaction to erastin is inhibited by heart shock protein beta 1 (HSPB1) [38].

Breast cancer

CDO1 (cysteine dioxygenase 1) overexpression may accelerate ferroptotic cell degradation by causing high-levels of reactive oxygen species to continue to accumulate due to the reduced glutathione content in mammary malignant cells. Ferroptosis is caused by an increase in iron-based ROS outputs. [39].

Rhabdomyosarcoma (RMS)

RMS cells must produce a lot of GSH in order to multiply and become resistant to drugs. RSL3 and erastin-induced GPX4 inhibition can cause RMS13 cells to undergo ferroptosis through reducing the glutathione concentration [40]. The heightened RMS13 cell lines sensitivity to erastin and RSL3 may also result from increased endogenous Ras/extracellular signal-regulated kinase activity.

Haematological cancers

The eight cell lines that were isolated from different tissues showed the greatest sensitivity to the ferroptosis inducer in diffuse large B-cell lymphoma cells [41]. According to research, the increased sensitivity may result from a deficit in the sulphur transfer pathways, which leads to an increase in Cys and Cys2 in extracellular spaces, which are essential for maintaining cells [42].

Hepatocellular carcinoma (HCC)

Ferroptosis was a key mechanism via which sorafenib cured hepatic carcinoma. Hepatic cancer cells with retinoblastoma protein inadequacy have a death rate that was two to three times higher compared to standard RB protein concentration [43]. Liver or hepatic malignancy with deactivated RB protein was more vulnerable to ferroptosis because of the increased oxidative stress response in cells caused by the increased reactive oxygen concentration in mitochondria. In HCC, inhibition of CDGSH iron sulphur domain 1 (CISD1) and ACSL4 promotes erastin-induced ferroptosis. The process by which low-density lipoprotein– docosahexaenoic acid nanoparticles destroy HCC cells is known as ferroptosis. Ferroptosis in HCC treatment is thought to be primarily targeted by the Ras/Raf/MEK pathway, while ferroptosis in HCC cells is prevented via the p62-Keap1-Nrf2 pathway. [44].

Therapeutic Applications of Ferroptosis

Inducers of ferroptosis

Inducers of ferroptosis are essential for relevant research. Selecting the right inducer based on aim and category may be essential for the pertinent study. This decision affects how the chosen inducer is acquired and how the research is conducted. Certain biological macromolecules with induction functions need plasmid manufacture, however kits based on small molecule inducers and medications have been created and made commercially available. Ferroptosis can be caused by a variety of medicines and small compounds, and their mechanisms are rapidly becoming understood. The most common kind of ferroptosis inducers are tiny compounds and medications, which primarily act on the targets and are easier to screen than other kinds of candidates. Depending on the inducers' goals, they can be studied under four categories [45].

Small molecular and inducers of drug

- Targeting molecules of iron metabolism

RSL5, DIDS, Erastin, initiate ferroptosis by targeting voltage-dependent anion channels (VDACs). Temozolomide (TMZ) enhance ferroptosis by targeting DMT 1, Ferritin heavy chain is destroyed by another molecule MMRi62 [45].

- Targeting metabolism of lipid

  Acyl-CoA synthetase family member 4 (ACSL4) is targeted by an antitumor drug used to treat the hepatic carcinoma, Sorafenib enhance ferroptosis with lipid metabolism. t-BuOOH also promote ferroptosis by oxidation of cardiolipins [45].
- Targeting gsh/GPx4axis

  RSL3, ML162, DPI7, DPI10, FIN56, Sorafenib especially focus on nucleophilic active sites, acting on Glutathione peroxidase 4 to promote ferroptosis. Glutamate Cysteine Ligase (GCL) is an enzyme used in formation of glutathione is degraded by Buthionine sulfoximine (BSO), therefore promote ferroptosis. System L, System Xc are targeted by the Erastin analoges like MEII, PE, AE, Sulfasalazine (SAS), Sorafenib. These directly donot promote ferroptosis but helps in degradation of GPX4 [45].
- Target coq /fsp1

  Ferroptosis suppressor protein 1 (FSP1) is targeted by NDP4928 that induce ferroptosis by inhibiting GSH. SQS FIN56 promotes ferroptosis process by binding to the squalene synthase (SQS) and 3 hydroxy-3-methylglutaryl-CoA reductase (HMGCR) is blocked by Statins in mevalonate pathway thus decrease in COQ and ferroptosis occur [45].
- Target other pathways

  Some of the inducers also show their effects such as dihydroorotate dehydrogenase (DHODH) is blocked by the Brequinar that can restrict the tumour growth. Dexamethasone induces ferroptosis by controlling dipeptidase-1 (DPEP1) [45].

Nanoparticles inducing ferroptosis

Cornell prime dots, SPION, GA-Fe (II), (UPDA-PEG) @$Fe^{2+/3+}$ nanoparticle promotes the production of iron ions there by enhance the cellular iron levels and promotes ferroptosis. WS2 and MoS2 also promotes ferroptosis by influencing the lysosomes leads to release of ferric ions into the cell. GSH uptake and Fenton- dependent reactions also enhance ferroptosis by other mechanisms with the help of certain nano particles like CoMoO4-phosphomolybdic acid nanosheets (CPMNS), low-density lipoprotein -docosahexaenoic acid nanoparticles, ChA and CQDs. Zinc oxide particles are also lethal that promotes ferroptosis. PMC Produce ROS directly [45].

Nucleic acid and proteins inducers

Regulation of ferroptosis also done by non-coding RNAs along with micro RNAs such as miR-672-3p by 6 regulating FSP1. System Xc- controls the interferon gamma (IFNγ), that is released by the CD^{8+} cells in immunotherapy. p53, BAP1 also associated with the process. TCA cycle is also an essential pathway regulates Glutamine that induces ferroptosis by cystine deficiency. ACSL4 and PKCβII induce ferroptosis by lipid peroxidation and Ferritin is regulated by NCOA4, cause ferroptosis by iron metabolism [45].

Potential for combination therapies

As previously highlighted, ferroptosis is often regarded as a well-known tumour suppressor in particular circumstances, despite having a dual role in the genesis of tumours. because it is possible to synthesise ferroptosis inducers, which have been proved in various in vivo tests. According to this theory, a large number of research have created several inducers to trigger ferroptosis and investigated its function in various cancer treatments, including immunotherapy, radiation, chemotherapy, and nano therapy.

Role of ferroptosis in chemotherapy

Ferroptosis in Conventional Cancer Chemotherapy Recent years have seen the invention of ferroptosis, a innovative approach of active cancer cell killing brought on by traditional chemotherapy medications. Cisplatin, for instance, primarily causes ferroptosis by directly reducing intracellular GSH, which in turn inhibits GPXs [46]. Furthermore, when ferritinophagy raises the quantities of free iron, cisplatin may also lead to ferroptotic cell loss mechanism. By restricting system X-c or GPX4 [47], ferroptosis inducers like erastin and RSL3 usually will increase the anticancer effects of cisplatin interactively when treating many cancer types, including lung carcinoma, colorectal carcinoma, ovarian cancer, and maligant pancreatic ductal adenocarcinoma tumours [47,48]. The first medication authorised for the treatment of hepatic cellular carcinoma and RCC is sorafenib. Current studies on colon cancer and pancreatic adenocarcinoma, however, have demonstrated that sorafenib's anticancer action primarily relies on inhibiting SLC7A11/GPX4 activity to cause ferroptosis; activating ferroptosis further enhances sorafenib's anticancer effect [49] Consequently, by inhibiting the X-c system or GPX4, ferroptosis-inducing drugs like erastin or RSL3 invariably enhance the anti-tumor characteristics of cisplatin when treating many cancer types, such as lung carcinoma, colorectal cancer, ovarian, and ductal carcinoma of the pancreas. By generating ROS, the histone deacetylase inhibitor (HDACi) suberoylanilide hydroxamic acid (SAHA) can further increase tumor susceptibility to the effects of cisplatin[50]. The therapeutic actions of artemisinin (ART) and its derivatives are linked to ferritinophagy-mediated ferroptosis [51,52]. ART and its derivative, dihydroartemisinin (DAT), can accumulate in the lysosomes and promote ferritin protein degradation [53], raising intracellular iron levels and promoting ferroptosis. Ferritin, an iron storage protein, binds to NCOA4 in the autophagosome and is transported into the lysosomes. By changing the proportion of iron-responsive elements (IRE) to iron-regulatory proteins (IRPs), DAT can also control iron homeostasis and raise intracellular free iron. Thus, in pancreatic ductal adenocarcinoma (PDAC), co-treatment with ART and transferrin (TF), which is in charge of delivering iron into cells, raised lysosomal free iron and encouraged ferroptosis [54].

These results established the door for the clinical use of innovative ferroptosis inducers and motivated us to investigate the possibility that other ferroptosis inducers could treat cancer on their own. Testing the effects of ferroptosis inducers in combination with other anticancer medications that are now available would also be intriguing. By upregulating GPX4 and the Xc-system, conventional chemotherapeutic drugs can also induce ferroptosis resistance and stop the death of cancerous cells. Gemcitabine's anticancer efficacy in pancreatic cancer is limited by ferroptosis resistance, which is mediated by the heat shock 70-kDa protein 5 (HSPA5)-GPX4 pathway [55]. By triggering the ATF4 and NRF2 pathways, temozolomide (TMZ) has been shown to enhance SLC7A11 expression at the mRNA and protein levels. Another chemotherapeutic medication used to treat head and neck cancer (HNC) cells is artesunate, which can also activate the NRF2-antioxidant response element pathway. In HNC, NRF2 inhibition reverses ferroptosis resistance and results in lipid lipoxidation [56]. Drug resistance remains a significant and intricate problem even with the therapeutic success of cancer chemotherapy. Thankfully, a few artificial and natural substances have shown encouraging results by promoting ferroptosis, successfully preventing acquired tumour drug resistance, and enhancing the effectiveness of cancer treatments.

Ferroptosis in radiation therapy for cancer

Since radiotherapy produces ROS by radiolysing water content in the cell, which damages biomolecules like lipids, it is hypothesised that it may be connected to ferroptosis. DNA double strand breaks are a direct consequence of the high-energy ionizing radiation (IR) used in radiotherapy [57]. Indirect effects like GSH depletion and ROS generation are also brought on by the radiation-induced breakdown of cellular water and the activation of oxidases. Lei et al. claim that in the majority of cancer cell lines, IR also increases the expression of ferroptosis markers like PTGS2. By

triggering the adaptive response of the ACL4/LPCAT3/ALOX and SLC7A11/GPX4 pathways, IR directly causes ROS. Cancer cells and xenograft tumors become more radiosensitive to infrared radiation when SLC7A11 or GPX4 is deactivated [58]. Following radiation and CD8+ T cell co-treatments, TFerroptosis has also been thought to be directly linked to better tumor control. The ataxia-telangiectasia mutant gene (ATM), which is activated by radiation therapy, and interferon (IFN), which is produced by active CD8+ T cells, combined to decrease SLC7A11 expression [59]. This extensive study used a novel approach to manage ferroptosis in order to enhance the therapeutic effects of radiation therapy or resolve radiation therapy resistance.

Ferroptosis in cancer immunotherapy

Ferroptosis role in immunotherapy is followed after conventional therapies like chemotherapy, radiation therapy along with surgery. Immune based therapy is a novel approach for treatment that may be able to completely remove or cure the cancer. However, one of the main causes of tumour immunotherapies with less effectiveness and a significant barrier to this approach is immune escape. Thus, one of the most important things to do to increase the effectiveness of tumour immunotherapy is to prevent the immune system from escaping. To improve anticancer effects, Ferroptotic cancer cells have the capacity to activate the adaptive immune system in the tumour microenvironment and continuously release immunostimulatory damage-associated molecular pattern molecules [60]. Bone-marrow-derived dendritic cells are phagocytosed by ferroptotic cells in response to three key DAMPs those are CRT, HMGB1 and ATP.

Additionally, neutrophils are drawn in by ferroptotic cancer cells via the TLR4/TRIF/type 1 IFN or Wnt signalling pathway [61,62], that are significant regulators and possible targeting against in therapy of the advancement of cancer.

Ferroptosis's function in nano therapy

Nano technology is new emerging technique in cancer treatment. Nanocarrier-based targeted drug delivery has the ability to raise the intracellular absorption capacity of medications, decrease their toxic and adverse effects to some degree, and boost the rate of drug utilisation [63]. Ferroptosis-dependent nano therapy works in three main processes: First, they can trigger or promote Fenton reactions in tumour cells. Nanoparticles are always designed to provide two basic elements of the Fenton response: Fe ions and (or) H2O2. Ferroptosis-combined cancer therapy is mainly based on iron-containing nanomaterials [64]. Second, ferroptosis driven nanotherapeutics are used as carriers of chemotherapeutic drugs or ferroptosis inducers to inhibit the expression of the GSH/GPX4 system in tumour cells [65]. Third, Through the use of oral PUFA supplementation or the delivery of PUFAs in nanoparticulate drug delivery systems, nanotherapeutics can exogenously regulate lipid peroxidation in tumour cells, hence causing ferroptosis in tumour cells [66,67]. Chemically or biologically loaded nanoparticles hold new promise for improving the effectiveness of current ferroptosis inducers and cancer treatments.

Challenges And Future Perspectives

Before ferroptosis-targeted treatment, its full potential to improve human health can be realised and a number of therapeutic obstacles must be overcome:

What chemical interactions that exist in ferroptosis and other traditional process of cell demise, and these routes be traced and included into the cellular process? As demonstrated by necroptotic cell death, may ferroptosis increase a cell's immunogenic nature to the vector and elicit an antigen specific immune reaction? In preclinical or clinical trials, do ferroptosis inducers effectively destroy cancer cells?

What will be the human toxicity profile and therapeutic window for a bioavailable ferroptosis inducer? What role does ncRNA have in controlling ferroptotic cell death?

It is possible that toxic effects may develop in some organs based on mice modelling and sparse human genetic data.

To create ferroptosis inhibitors that are suitable for clinical application, more research is needed. There is a need for more efficient and easily available biomarkers to report ferroptosis in biological samples and patients.

Currently, ferroptosis inhibitor-based functional tests are needed to determined.

All things considered, ferroptosis has raised our expectations for a novel strategy in anti-tumor treatments. Ferroptotic cell death is emerging as a new cell death for the goal of eliminating resistant or remaining cancer cells, which has been the primary focus of current research. Presently, numerous ferroptosis reviews have concentrated on providing an overview of the processes of ferroptosis depended on lipid metabolism, glutathione/glutathione peroxidase 4, and other controlled mechanisms. The second focusses mostly on compounds that function as inducers and inhibitors, such as tiny molecules and nanoparticles, and how they are used in cancer treatment. It's also important to note that the numerous physiologically active species that participate in ferroptosis. The two biggest challenges to eliminating cancer are acquired resistance and insensitivity. The sensitisation and synergistic effects of inducers of ferroptosis make them interesting for use in oncotherapy. The limitations of conventional medications and ferroptosis inducers with limited solubility nature and membrane penetrability may be solved by combining ferroptosis with emerging biotechnologies like ferroptosis-driven nanotherapeutics. Additional research and clinical trials are still necessary because of the intricacy of the biological system and the challenge of clinical translation [68,69].

CONCLUSION

Ferroptosis type of programmed cell loss characterised with the buildup of ROS species and an excess of peroxidation of phospholipids, in like manner to apoptosis caused by iron-mediated lipid peroxidation. Targeting the cell death process is a common strategy in cancer treatment, and ferroptosis is believed to play a major role in anticancer medications in recent years. The ferroptotic mechanisms in overcoming drug resistance in preclinical studies are compiled in this article. Examined the role ferroptosis played in cancer therapy based on research conducted to date. Through various molecular processes, many therapies, such as chemical, specific medicines, radiation therapy, and immune-based therapies, cause ferroptosis to decline tumour cells. Here, we also highlight its role in chemotherapy and nanotechnology, as well as the challenges and strategies to enhance ferroptosis, along with future perspectives. It is a new innovative mechanism raised hope for the cure of cancer in future.

ABSTRACT

Software defect prediction (SDP) is a very crucial aspect of software engineering, which helps to enhance software reliability and to minimize the costs of its maintenance. The current techniques such as existing machine learning and ensemble techniques are usually associated with major constraints, which include class imbalance, high dimensional feature space, and non-linear relationships in software metrics. These limitations may cause unstable predictions, increase the false positives or negatives, and poor advice to the software developers. The present paper attempts to eliminate these problems by outlining a Hierarchical Multistage Consonance Deep Classifier (HMC-DeepClassifier), which is a deep ensemble-based model that obtains multilevel feature representations by hierarchical extraction through lines of code, cyclomatic complexity, cohesion, and coupling software metrics. The suggested model combines LeakyReLU activation, Batch Normalization, Dropout, and L2 regularization to stabilize the learning process and prevent overfitting, and adaptive optimization with AdamW and Cosine Annealing to have a smooth learning process and better generalization. The predictions of the model can be applied by the software developers to obtain actionable knowledge on how to overcome the defect-prone modules early and on how to allocate the testing resources. Comparative experiments used that the proposed method has high accuracy, precision, and recall as well as F1-Score and beats existing methods. HMC-

DeepClassifier consequently is a robust and scalable tool in defect prediction ideally applicable to large-scale and safety-critical software environments, where predictable and reliable defect detection can greatly enhance software reliability and decrease software development expenses.

Keywords: Adaptive Optimization, Deep Learning, Ensemble Model, Feature Representation, Software Defect Prediction, Hierarchical Neural Network

INTRODUCTION

SDP is essential for improvingthe reliability of software and low maintenance effort. In recent research, many methods have been suggested to better predict errors in defects. A lean method was created to forecast test failures that were caused by software bugs, and this shows that it can be applied by the industry [1]. The method of cross-project SDP through metric reduction and hybridization has been studied in order to enhance the generalization of the models [2]. Comparative studies of distance measures in K-Nearest Neighbors (KNN) and SMOTE algorithms have revealed the need to address the issue of class imbalance in the datasets of defect prediction [3]. There are also model averaging methods that have been used in within-project and cross-project defect prediction and have been found to have better predictive stability [4]. Combined approaches to test case prioritization, defect prediction and resource allocation techniques have been suggested to make software quality optima [5]. More convergent and more correct SDclassification was achieved with adaptive ensemble learning models that employed binary white shark optimizers [6]. Ensemble based ML algorithms with the NearMiss method has been used successfully in solving class imbalance in software bug prediction [7]. Combined methods involving the use of ML, deep learning and feature selection have enhanced software vulnerability assessment and classification [8]. Improved feature selection with ensemble ML has been demonstrated to be more successful in defect prediction [9].

Many LSTM networks that are directional coupled with an oversampling technique have enhanced the predictive capabilities of sequential software data in a considerable way [10]. Reliable hybrid models have been established based on explainable AI to predict software defects transparently [11]. Predictable defects models that can be interpreted through the use of project effort and other metrics with the use of static code have given developers reasonable actionable information [12]. In defect prediction, adaptive algorithm based feature selection techniques have been used to overcome high dimensional feature problems [13]. Other applications of deep reinforcement learning on the just-in-time prediction of software defects have aimed to minimize false positive and enhance real-time prediction [14]. War strategy optimization and Kernel Extreme Learning Machine (ELM) have been used to improve IoT-based SDP showing that they can be applied in the area of analytical data management [15]. ANFIS has been used in combination with turbulent flow of water optimization algorithms to address uncertainty problems in defect prediction [16]. The methods of fusion of predictive learning on three-line hybrid features have enhanced prediction by using improved feature engineering [17].

Contribution: The primary value of the paper is a hierarchical ensemble-based deep learning model, the HMC-DeepClassifier which provides high accuracy and balance in SDprediction. It is more effective in managing the imbalance of classes, stabilizing learning, and offering software development insights.

Organization: The organization of the paper is described below. Section 1 presents an introduction to SDP and discusses its importance to improving software quality and software maintenance costs. Section 2 provides some background and related work, including ML methods and hybrid methods for defect prediction. Section 3 materials and methods presents the dataset and the detailed materials of HMC-DeepClassifier methods proposed in the study. Section 4 provides results and the evaluation of the classification methods for the studies conducted. Finally, Section 5 concludes the paper

Background Study

SDP still happens to be one of the most important concerns that enhance software reliabilityand lower maintenance overhead. The authors of the article Khalid *et al*. (2023) [18] applied ML to SDP and demonstrated that proper choice of features and model testing are crucial to the higher accuracy of the prediction. In reference [19] Giray *et al*. explored the issue of deep learning to predict defects, and they showed that they enable handling complex software data sets and increasing the quality of predictions. To further improve the accuracy of the model in general and high-dimensional data in particular, Chen, Wang, and Song (2022) [20] proposed the use of the nested-stacking feature selection and heterogeneous feature selection. The article designed by Tang *et al*. (2023) [21] proposes an ensemble learning algorithm as an adaptive variable sparrow search algorithm, and it has demonstrated the possibilities of enhancing prediction efficiency with the application of metaheuristic optimization. A binary chaos based metaheuristic algorithm as proposed by Arasteh *et al*. (2024) [22] improved the convergence and exploration capability of SDP problems. Alazba and Aljamaan (2022) [23] applied the generalization concept by stacking with optimized tree based ensembles that led to significant enhancement of the predictive power owing to the application of complementary models. Another example of how the prediction of defects models can be extended to cybersecurity more generally is provided by Hajjouz and Avksentieva (2025) [24], who applied the CatBoostalgorithm to accurate detection and classification of DoS and DDoS attack subtypes in network traffic. XGBoost using optimal hyperparameters to predict software defects was used by AL-Hadidi and Hasoon (2024) [25] to emphasize the need to optimize model parameters. The article by Wang *et al*. (2025) [26] used ensemble TabNet with explainable AI to identify urinary tract infection after pediatric pyeloplasty and demonstrated how interpretable predictive models can provide reliable and actionable information in the healthcare field and others. A combination of studies has shown the development of SDP to go beyond Existing ML into hybrid metaheuristic strategies, deep learning, and explainable AI strategies and methods, showing the increased prominence of model optimization, interpretability and generalization across varied datasets and tasks.

MATERIALS AND METHODS

This section develops and describes the HMC-DeepClassifier to be used aimed at predicting software defects. It concerned with the structure of a hierarchical deep neural network, which generates multilevel feature representations using software measures (LOC, cyclomatic complexity, and coupling). The section describes the structure of the model, mathematical equations, and the learning algorithm, emphasizing the combination of such techniques as LeakyReLU activation, Batch Norm, Dropout, L2 regularization, AdamW optimization, Cosine Annealing, to increase the stability of learning, generalization, and predictive power. HMC-DeepClassifier Overall Architecture (Figure 1). This figure 2 indicates all architecture of the HMC-DeepClassifier. It depicts processing of input software metrics in hierarchical dense layers, loss and optimization, regularization methods and ensemble training methods used to stabilize the learning. Lastly, the model generates predictions and measures of evaluation, which underscores its high level of software error prediction.

Dataset Information

https://www.kaggle.com/datasets/ziya07/software-defect-prediction-dataset

This dataset on SDP at Kaggle includes a range of metrics of software modules (LOC, CYCLO, LENGTH, etc.) and a target label that is a defective software module or not. The dataset is usually employed in constructing and testing software quality assurance predictive models. It gives an empirical standard of comparison to classification algorithms in defect detection programs.

Hierarchical Multistage Consonance Deep Classifier (HMC-DeepClassifier)

The Hierarchical Multistage Consonance Deep Classifier (HMC-DeepClassifier) is a deep ensemble-based deep learning model that was created to resolve an issue of software defects prediction in a highly accurate and reliable manner. The network is hierarchically structured with the input features passing through a set of successively smaller layers with correspondingly smaller dimensionality. The gradual overlaying enables the network to not only

extract the broad but also finer patterns on the data in a manner that the information of relevance is preserved through the various stages. The similarity of approaches is that every tier has a suitable approach to learning non-linear association, Batch normalization is a suitable approach to stabilising the activation distributions, dropout is a suitable method of overfitting reduction and L2 regularisation is a suitable approach of promoting generalisation. This will be multistage consonance process to make sure that the model is not unstable bearing in mind complexity in the process of learning. To simplify the learning task further, AdamW optimizer, which is a combination of adaptive gradient descent and decoupled weight decay, hence higher convergence speed and stability are achieved is implemented. Besides, a complex scheduling algorithm, such as Cosine Annealing and Reduce LROnPlateau, is also used to dynamically adapt the learning rate to enable a more gradual transition to discouraging early plateauing.

The process of saving the optimum weights and to prevent overtraining also involves early termination. In order to achieve the robustness, the model is trained using a number of random seeds whose prediction is averaged through the ensemble that causes the model to be sensitive to noisy at the start of a prediction and enhances its stability. In the case of SDprediction, the HMC-DeepClassifier will be fed with hidden patterns of both software quality measures such as lines of code, cyclomatic complexity, cohesion, and coupling and the historical bug data. Existing ML models would be unable to address the non-linearity and dimensionality of such data as the HMC-DeepClassifier can optimize the features representation in a hierarchical order and provide reasonable predictions of defects. The correct identification of modules as defect prone or not defect prone will provide actionable information, which could be directly put in place into actual software development pipelines, like, continuous integration and continuous deployment (CI/CD) systems. This enables automatic check of code commits and vulnerable modules that have been detected before to enable the developers to do more significant checkout and debugging.

Therefore, HMC-DeepClassifier not only increases the predictive accuracy but also the cost reduction and the software reliability and quality assurance of the large scale and safety-critical software engineering projects. The workflow of the HMC-DeepClassifier model is as shown in figure 2. It starts with the Data Input into the deep neural network where it traverses through various Dense Layers and it adopts Leaky ReLU activation function. This is then succeeded by a Loss Function and Optimization block to train and optimize the model Binary Crossentropy and Adaptive Gradient Descent with decoupled weight decay. Lastly, the results undergo the procedures of Ensemble Aggregation and Weights Importance Score and lastly, the Model Evaluation and Final Output processes the results and completes the result process.

$$h^{(l)} = f\left(W^{(l)}.h^{(l-1)} + b^{(l)}\right) \text{ ---------- (1)}$$

This formula 1 represents the output of the l^{th} layer in the HMC-DeepClassifier. Here, $h^{(l-1)}$ is the input from the previous layer,$W^{(l)}$ and $b^{(l)}$ are the weights and bias of the current layer, and $f(.)$is the non-linear activation (LeakyReLU in this model). The operation combines linear transformation and non-linear activation to derivehierarchical features from the input data.

$$f(x) = \begin{cases} xifx > 0 \\ \alpha xifx \leq 0 \end{cases} \text{----------} (2)$$

This formula 2 is the LeakyReLU activation function used in the HMC-DeepClassifier. Here, $x$is the input to the activation, and α is a small constant (0.1 in this model) that allows a small gradient when$x \leq 0$. This prevents neurons from "dying" during training, enabling the network to learn non-linear relationships effectively.

$$\hat{h}^{(l)} = \frac{h^{(l)} - \mu_B}{\sqrt{\sigma_B^2 + \epsilon}} . \gamma + \beta \text{ ---------- (3)}$$

This formula 3 represents Batch Normalization in the l^{th} layer of the HMC-DeepClassifier. Here, $h^{(l)}$ is the layer input, μ_B and σ_B^2 are mean and variance of the current batch, ϵintroduced to maintain numerical stability, and γ, β are

learnable parameters that scale and shift the normalized output. This operation stabilizes the layer activations, accelerates training, and improves model convergence.

$h_{drop}^{(l)} = h^{(l)} \odot Y, \quad Y_i \sim Bernoulli(\mathrm{p})$ -------- (4)

This formula 4 speak for Dropout applied to the l^{th} layer of the HMC-DeepClassifier. Here, $h^{(l)}$ is the input to the layer, Y is the dropout mask vector, and each element Y_i is explicitly sampled from a $Bernoulli$ distribution with probability p. The element-wise multiplication ⊙selectively suppresses neurons during training, which prevents co-adaptation, reduces overfitting, and improves the model's generalization ability.

$L_{reg} = \lambda \sum_l \sum_{i,j} \left(W_{ij}^{(l)}\right)^2$ ---------- (5)

L2 regularization applied to the HMC-DeepClassifier is represented by formula 5. Here, λ is the regularization coefficient that regulates the penalty's severity, and $W_{ij}^{(l)}$ is the weight that connects the i^{th} neuron of layer l-1 to the j^{th} neuron of layer l. By penalizing big weights and promoting smaller, more stable weights, the summation of all weights in all layers lowers overfitting which strengthens the model's generalization capabilityon unknown input.

$L = -\frac{1}{N}\sum_{i=1}^{N}[y_i log(\hat{y}_i) + (1+y) log(1-\hat{y}_i)]$ ---------- (6)

This formula 6 speak for the Binary Crossentropy Loss used in the HMC-DeepClassifier. Here, $y_i$represents the ground-truth label of thei^{th} sample $\hat{y}_i$represents the predicted probability produced by the model, and N is the total number of samples. The loss computes the average penalty for incorrect predictions, where $-y_i log(\hat{y}_i)$ penalizes false negatives and $-(1+y)log(1-\hat{y}_i)$ penalizes false positives, guiding the network to accurately classify defect-prone and non-defect-prone software modules.

$\theta_{t+1} = \theta_t - \eta \lambda \theta_t$ ---------- (7)

This formula 7 speak for the weight update with AdamW optimizer in the HMC-DeepClassifier. Here, θ_t is the weight parameter at iteration$t$, θ_{t+1} is the updated weight, η is the learning rate, and λ is the weight decay coefficient. The second term $(\eta \lambda \theta_t)$ explicitly applies decoupled L2 regularization, which prevents weights from growing too large, stabilizes training, and improves the generalization of the model.

$\eta_t = \eta_{min} + \frac{1}{2}(\eta_{max} - \eta_{min})\left(1 + cos(\pi t/T)\right)$ ---------- (8)

Formula (8) defines learning rate schedule employing cosine annealing, which smoothly reduces the learning rate during training. In this formula, η_t denotes the learning rate at iteration t,η_{min}denotes the lower bound of the learning rate, and η_{max}denotes the maximum learning rate. The term T represents the total number of iterations in one annealing cycle, while the $cos(\pi t/T)$ component governs the gradual decay. As the iteration t progresses from 0 to T, the value of η_t decreases from η_{max} to η_{min} in a cosine-shaped curves, ensuring a smooth and stable convergence of the model.

$\hat{y}_i = \frac{1}{M}\sum_{m=1}^{M} \hat{y}_i^{(m)}$ ---------- (9)

Formula (9) speak for the ensemble prediction averaging process, where $\hat{y}_i$ is the final predicted value for the i^{th} sample. Here, M denotes the total number of models in the ensemble, and $\hat{y}_i^{(m)}$ represents the prediction of the m^{th} model for the same sample. By averaging the outputs of all M models, this equation reduces individual model biases and variances, resulting in a more robust and accurate final prediction.

$s_j = \frac{1}{N}\sum_{i=1}^{N}\left|W_{ij}^{(1)}\right|$ ---------- (10)

Formula (10) defines the feature importance score based on the neural network's first-layer weights. Here, $s_j$represents the importance scores of the j^{th} feature, N is the total number of neurons in the first hidden layer, and $W_{ij}^{(1)}$ denotes the weight connecting the j^{th}input feature to the i^{th} neuron in the first layer. The absolute values of these weights are averaged across all neurons, meaning that features with larger average absolute weights s_j contribute more significantly to the model's predictions.

Algoithm 1: Hierarchical Multistage Consonance Deep Classifier (HMC-DeepClassifier)

Input:
X_train_selected, y_train
X_test_selected, y_test
seeds = [1,2,3]
epochs, batch_size Output:
y_pred
y_pred_prob
Step 1: Define HMC-DeepClassifier Model
- Input Layer: shape = number of selected features
- Dense Layer 1: 512 units, L2 regularization
- Dense Layer 2: 256 units, L2 regularization
- Dense Layer 3: 128 units, L2 regularization
- Dense Layer 4: 64 units, L2 regularization
- Output Layer: 1 unit, Sigmoid activation

Step 2: Compile Model
- Loss: Binary Crossentropy
- Optimizer: AdamW (learning_rate=0.001, weight_decay=1e-5)
- Metrics: Accuracy

Step 3: Define Callbacks
- EarlyStopping: monitor val_loss, patience=15, restore best weights
- ReduceLROnPlateau: monitor val_loss, factor=0.5, patience=7, min_lr=1e-6
- CosineAnnealingLearningRateScheduler

Step 4: Ensemble Training
Initialize ensemble_predictions = []
For each seed in seeds:
- Set random seed
- Initialize HMC-DeepClassifier
- Train model on X_train_selected, y_train with validation X_test_selected, y_test
- Store predicted probabilities on X_test_selected in ensemble_predictions

Step 5: Aggregate Ensemble Predictions
- y_pred_prob = Average(ensemble_predictions)
- y_pred = Convert probabilities > 0.5 to 1, else 0

Step 6: Evaluate Model
- Compute Accuracy, Precision, Recall, F1-Score
- Compute Confusion Matrix
- Plot Confusion Matrix

Return y_pred, y_pred_prob

The Hierarchical Multistage Consonance Deep Classifier (HMC-DeepClassifier) can be described as an ensemble-based deep neural architecture in Algorithm 1 which is designed by the author to perform powerful binary

classification. It is made up of numerous thick layers whose activation can be LeakyReLU, batch normalization, dropout and L2 regularization to stabilize it and avoid overfitting. Adaptive learning is built based on Cosine annealing and early stopping and AdamW optimization. Lastly, the ensemble output is the approximate output that is approximated by averaging the outputs of the predictions of several random seeds, which improves accuracy and generalization.

RESULT AND DISCUSSION

In this section, the show analysis of the proposed HMC-DeepClassifier is presented using the assistance of Python, which is executed in the Spyder IDE. Various show measures were calculated and plotted to compare the proposed model with other ML models like XGBoost, CatBoost and TabNet. The model was also tested on the sizes of training data. These analyses underline the truth of the fact that the state of training set improvements the classification potential of the model at a lethal pace. These results exemplify the effectiveness of the model in the coming up with the software defects which have a high detection accuracy and even-handed performance. Figure 3 illustrates the distribution of a software dataset in terms of defects presence. It demonstrates that most of the data, namely 67.4% is the Non-Defective modules which are represented by the green slice. The other segment, 32.6 is Defective modules, and it is depicted with red color. which instances that are not defective are more than those that are defective. This figure 4 indicates the Optimized Confusion Matrix of the HMC-DeepClassifier model, which summarizes the classification outputs of the model evaluated on the test set, which yielded surprisingly high results and was able to properly classify 383 cases of Class 0 (True Negatives) and 206 cases of Class 1 (True Positives). The mistakes are negligible: it made 6 False Positives (misclassified as Class 1)and 5 False Negatives (instances of Class 1 incorrectly predicted as Class 0). Having 600 examples, the accuracy of the model is quite high (383+206=589 correct predictions) which proves that the model performs well and has a good balance in terms of classifying negative and positive cases.

Accuracy

Accuracy is a measure of how accurate a classifier is, it is determined by determining the percentage of the correctly predicted instances in relation to all predictions. This is calculated by the following formula 10.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \times 100 \text{---------- (11)}$$

TP (True Positives) are instances correctly predicted as positive, TN (True Negatives)are cases correctly classified as negative,FP (instances of negative samples incorrectly predicted as positive)are samples inaccurately classified positive and FN (instances of Class 1 incorrectly predicted as negative) are instances inaccurately predicted negative. Accuracy is therefore a percentage of the total predictions made by the model and are classified correctly.

Precision

Precision quantifies thecorrectness of positive predictions of a classifier. It is calculated as

$$Precision = \frac{TP}{TP+FP} \times 100 \text{ ---------- (12)}$$

The Formula 11 True Positives (TP) is the right positive cases and False Positives (FP) is the wrong positive cases. Precision is the percentage of correct prediction of positives.

Recall

The recall is used in measuring how well a classifier can detect all true positive cases. It is the formula 12calculated as

$$Recall = \frac{TP}{TP+FN} \times 100 \text{ ---------- (13)}$$

False Negatives (FN) are real positive cases that were mistakenly predicted as negative, while True Positives (TP) are accurately predicted positive examples. The percentage of true positives that the model properly detected is known as recall.

F1-Score

F1-Score is the harmonic mean of Precision and Recall, providing a balanced measure of a classifier's performance. It is calculated using Formula 13 as

$$F1 - Score = 2 \times \frac{Precison \times Recall}{Precison + Recall} \text{ ---------- (14)}$$

The F1-Score is the ratio of $Precison$ and$Recall$, therefore it is particularly useful in using models on an imbalanced dataset.

Table 1 show comparison illustrates that the proposed HMC-DeepClassifier performs much better than the traditional ones CatBoost, XGBoost, and TabNet. CatBoost and XGBoost have moderate performance with less precision and recall meaning they have high false positives and false negatives. TabNet shows significant increases in all measures. Notably, the HMC-DeepClassifier has outstanding accuracy (98.17%), a very balanced show in precision (97.17%) and recall (97.63%) with a high F1-Score of 97.40% indicating its good overall classification and good balance score between precision and recall. This figure 5 presents the performance of four ML models in classification through Accuracy (%). The highest accuracy of the HMC-DeepClassifier is 98.17, which is much higher than that of other models. TabNet has a modest 86.44%. The lowest accuracies of 72.46% and 63.00 in XGBoost and CatBoost, respectively, are recorded by the gradient boosting models. The chart shows clearly that the HMC-DeepClassifier is the best model in this activity in the measure of accuracy. This figure 6 shows the Precision (%). The HMC-DeepClassifier has the best precision of 97.17 which means there is least false positive errors. The second-best performer is tabNet with the show of 81.34%.

XGBoost and CatBoost gradient boosting models follow at a far behind with precision values of 69.65% and 41.18 respectively. This evidence shows clearly the high reliability of the HMC-DeepClassifier in positive predictions. The figure 7 Recall Comparison Across Models and it is the show of four ML models in terms of Recall (%) performance. The most appropriate model is the HMC-DeepClassifier model that has an excellent recall of 97.63 that is very high and it is excellent in the detection of positive cases. TabNet is the second-best at 79.64%. XGBoost and CatBoost are then performing significantly lower with 68.83 and 32.31, respectively. This chart clarifies that the best model to be used in this task in order to minimize false negatives is the HMC-DeepClassifier. This figure 8 contrasts the performance of the balanced classification of four ML models. The HMC-DeepClassifier has the best F1-Score (%) of 97.40 and this is an excellent balance between precision and recall. The second-most popular model has a score of 79.12% and is called TabNet. On the contrary, XGBoost and CatBoost follow behind at 68.59% and 36.21 with F1-Scores respectively. This chart conclusively proves the HMC-DeepClassifier as the most successful model in the two metrics. The table 2 shows how performance of different models can be influenced by the different sizes of training data. Reducing the size of training sets to 40 and 50 per cent leads to low accuracy and poor performance in terms of recall, precision, and F1-Score, which means that the learning is inadequate and the rate of misclassification is high. When the training data is increased to 60 percent the metrics are improved, but performance is average.

The offered 70% training sample size is the one that attains a significant gain, which is the Accuracy of 98.17, Precision of 97.17, Recall of 97.63, and F1-Score of 97.40, that is, sufficient training data is essential to a strong generalization of the model and a high quality of defect detection. The figure 9, Accuracy vs Training Data Size, shows the relationship between the Accuracy (%) and the proportion of data used to train the model as the proportion of data used to train the model increases. The accuracy has a slowly increasing pattern of 56. 25% training size to 67.50% training size. Nevertheless, the dramatic increase is seen with the extension of the training size to the Proposed 70% where the accuracy takes a high of 98.17. This speaks volumes of the fact that the ideal performance of

the model is highly reliant on a more significant training dataset. This is Figure 10, Precision Distribution by Training Data Size where the cumulative precision of the different sizes of the training data is displayed. The 70% (Proposed) size of the training size would be the largest contributor of the overall precision (or contribution to the maximum precision of the model) of 44.3 percent. The remaining sizes are contributing decreasingly with the largest contribution of 22.8 by the 60 percent, the largest contribution of 19.9 by 50 percent and the smallest contribution of 13.0 by 40 percent. The illustration brings to the fore the fact that greater accuracy performance of the model is highly reliant on the greater training dataset that is proposed to be utilized which assumes the form of 70 percent.

This Figure 11, Recall vs Training Data Size indicates how the training data size affects the Recall Percentage of the model drastically. The recall is not very high though at the smaller training sizes where recalling of 40 percent is 23.08 percent and 50 percent is 21.21 percent but then sharply increases to 49.46 percent at 60. However, the model performs better at the optimum training size of 70 percent (Proposed) and achieves great recall of 97.63. This makes it quite apparent that this model is highly recall-sensitive and requires as much training set as possible to ensure that it is able to minimize the occurrence of false negatives. According to the figure 12 F1-Score vs Training Data Size it can be seen that the model F1-Score (%) has a close positive correlation with the size of the training data. F1-Score is very low in case of smaller training sets (40% and 50%), namely, 25.53 and 28.57 respectively. The growth of performance amazingly grows to 49.32% when the size is 60% but this time the performance growth is at 70% (Proposed) training size, by an unbelievable percentage up to 97.40. This demonstrates that the model requires substantial training data in order to bring the best and fair outcomes on classification .

CONCLUSION

The Hierarchy Multistage Consonance Deep Classifier (HMC-DeepClassifier) is suitable in the issue of software defects prediction since it relates to hierarchical processing of software measurements in lines of code, cyclomatic complexity, cohesion, and coupling to derive multilevel features representations. The approach not only restores coarse and fine grained patterns but also a combination of LeakyReLU activation, Batch normalization, Dropout, and L2 regularization ensure high learning, reduces the overfitting, and enhances generalization. Adaptive learning with AdamW, Cosine Annealing and early stopping can be used to ensure that convergence is stable and predictive power and multiple model ensembles can be used to enhance the reliability once more, as this reduces variance. The model has been demonstrated to be more effective as compared to the traditional methods which are high-accuracy, high-precision, high-recall, and high-F1-Score, and can address the accurately identify the defect-prone software modules to provide actionable recommendations to developers. The hierarchical feature extraction the use of ensemble learning and adaptive optimization are facilitated by the apprehending of inherent and complex trends in software information and this model is suitable to the scale-intensive and safety-concerned software system. Its primary areas of work to be improved include the extension of the technique to cross-project prediction, new software metrics in real-time, and the introduction of techniques to assure interpretability to maintain quality proactively. Besides, the model can be carried out in continuous integration pipelines to support automated defect detection and preventive maintenance, which can also contribute to improved software reliability, reduced costs of development, and the overall enhanced quality assurance of software engineering programs.

ABSTRACT

Organisational recreational activities are essential in IT companies as they enhance team bonding, encourage a healthy work-life balance, and elevate employee morale and productivity. These activities offer a necessary respite from the challenging and frequently stressful projects that IT professionals face daily. Hence, the researchers have studied the perception of employees towards employees' recreational activities conducted by IT companies in Puducherry union territory. The researchers selected 572 employees using simple random sampling method from Puducherry union territory. Primary data were collected through a well-structured questionnaire. The researchers applied the statistical tools of simple percentage, mean, standard deviation, coefficient of variation, cluster analysis, factor analysis and regression analysis as statistical tools. The researcher found that the frequency level of participation was high for 'musical and dance events', and outdoor events was found to be the least frequently participated organisational recreational activities in the study area.High positive perception by the respondents was found towards organisational recreational activities in the sample companies in the dimension of "Organising method" followed by "Benefits Attained" and "Suitability". It was also evidenced that the frequency of participation in organisational recreational activities in the divisions of 'indoor events', 'musical and dance events' and 'outdoor events' are positively and significantly influenced the perception level of the respondents towards organisational recreational activities.

Keywords: IT Professionals, Healthy Work Life Balance, Employees' Recreation, Work Environment, Suitability.

INTRODUCTION

Organisational recreational activities play a vital role in IT companies by fostering team bonding, promoting a healthy work-life balance, and boosting employee morale and productivity. These activities provide a much-needed break from the demanding and often stressful projects that IT professionals tackle on a daily basis. By engaging in recreational activities such as team sports, outings, or wellness programs, employees can recharge their batteries, reduce burnout, and improve their overall well-being. Moreover, these activities help create a positive work environment, improve communication among team members, and strengthen relationships, ultimately leading to increased collaboration and creativity within the company. In the fast-paced world of IT, prioritizing organisational recreational activities can have a significant impact on employee satisfaction and retention rates.

In the fast-paced environment of IT companies, where stress and deadlines often occupy center stage, employees' recreational activities emerge as a vital component of workplace culture. These activities are designed not only to foster teamwork and collaboration among employees but also to enhance overall job satisfaction and employee well-being.Understanding employees' perceptions of these recreational activities is crucial for organizations aiming to create a positive workplace atmosphere. Different facets, such as participation rates, enjoyment levels, and perceived benefits, can provide insight into how effectively these activities meet the needs and expectations of employees. As we delve into this exploration, we aim to evaluate various perspectives on recreational activities provided by IT companies. By gathering feedback and analyzing employees' opinions, we can identify potential improvements and opportunities that could lead to a more engaging and fulfilling work environment.In the article we have examined the frequency of participation of employees in organisational recreational activities, their perception towards various aspects of employees' recreational activities and relationship between themUnderstanding these dynamics will help organizations tailor their offerings to align with employee interests, ultimately fostering a more cohesive and motivated workforce.

REVIEW OF LITERATURE

Mutangwa., Ramathuba T., & Mabunda (2018)analysedthe perceived factors influencing participation of non-medical staff members in workplace sports and recreation at a selected hospital. The study found that majority of respondents did not partake in sports and recreation activities and half of the respondents did not perceive themselves as being susceptible to non-communicable diseases, but strongly agreed that physical inactivity could lead to development of non -communicable disease and death. Mogeni L.K., Ngugi P.K., & Odhiambo R., (2019) examined the influence of recreational services on employee retention of commercial banks in Kenya. The results of regression analysis revealed that there was a significant positive influence of recreational services on employee retention. The study recommended that there was need to develop recreational program aimed at fostering a work life balance.Enenifa C.E., &Akintokunbo O.O. (2020) examined the relationship between workplace recreational activities and employee effectiveness in Deposit Money Banks in Yenogoa, Bayelsa State in Nigeria. The results of the study showed that there was a significant the relationship between workplace recreational activities rand employee effectiveness in Deposit Money Banks in Yenogoa, Bayelsa State. The study suggested that management of Deposit Money Banks should create avenues for workplace recreational activities for its employees because it not only polishes the employee skills but also prepare them to accomplish the current and future challenging assignments.

Kavitha J., & Gopinath R. (2020)studied Workplace entertainment among college teachers on work engagementin Tiruchirappalli District, Tamil Nadu. The found that workplace entertainment had both positive and negative effect on the work engagement of college teachers. Socialising with co-workers and Personal freedom at work had positive effect on factors like cognitive, emotional and social work engagement while celebration at work had positive effect on emotional work engagement and negative effect on cognitive and social work engagement of teachers. Gupta V., Mishra N., & Devi T.S., (2021) studied about organisational recreation and relationship between physical activity in

recreation and work performance of employees. The study stated that three essential subjects rose up out of the information assortment: administration, social help and holding, and compromising requirements for benefits. Pioneer transport was significant on account of the common duty among members. Social help came in both various levelled and horizontal manners. Sumayya U., Amen U., & Imran R. (2021)examined the contribution of fun in improving the creative performance of employees in the private banking sector. The researchers found that the selected variables significantly related in improving creative performance of employees. The study also showed that three of the hypotheses were accepted whilst, the one hypothesis was rejected. The study concluded that to generate productive results and creative performance organizations should focus on the techniques to engage people. These simple strategies with low cost can benefit the banks in long run.

Kartini D., &Ibrahim A. (2021) explored the employees' perception regarding the effect of using humour in workplace to reduce job stress. The finding of the study showed that all informants feel stress with their job and the use of humour was able to reduce their stress at workplace. All informants preferred to use verbal humour when they felt stress at workplace because it increased individual's self esteem, work quality and work spirit. Apart from that, benefit of humour was also to build rapport and initiate friendship. Jain V., & Anand M., (2022) studied the effect of participating in recreational activities on stress management. The study stated that the employees seemed to be inclined towards the opinion that recreational programs were positively affecting their work by helping them bond with their colleagues, enabling greater interaction and sparking creativity, eventually leading them to cope with stress caused due to work-related and personal factors. Sariyildiz A.Y., Aksoy Y., & Akça G., (2022) investigated the effect of recreational activities on the job satisfaction of health workers. The study determined that the internal job satisfaction factor of the Job Satisfaction Scale differed significantly in terms of medium and high monthly income. The study also found that there was a significant difference in all factors of the Job Satisfaction scale in terms of the variable of being a smoker. The study also determined that health professionals who used alcohol and participate in recreational activities had higher job satisfaction styles in all factors than health professionals who did not drink and participate in recreational activities.

Mercanoglu A.O., & Simsek K.Y., (2023)studied the impact of employee recreation on their respective productivity. The study stated that an employee recreation program covered 6 days a week was used as the intervention. The program was implemented for 6 weeks. The study found significant differences in both within-group and between-group comparisons. The study also found that the employee recreation program had a large and positive effect on employee productivity.Suwal R., & Uprety P., (2023) analysed the impact of recreational activities on employees' productivity of Nepalese commercial banks The study concluded that there was a moderate positive relationship between each independent variable, i.e., physical fitness activities, mental health activities and entertainment activities and dependent variable, i.e., employees' productivity. Two independent variables, i.e., physical fitness activities and entertainment activities had a significant positive impact on employee productivity. The study also found positive impact of recreational activities on employees' productivity.

Objectives

- To study the frequency of employees' participation in employees' recreational activities in the selected IT companies.
- To assess the perception of employees towards employees' recreational activities in the selected IT companies.
- To examine the influence of frequency of participation in OR on perception of the employees on OR in the study units.

METHODOLOGY

The researchers have studied the perception of employees towards employees' recreational activities conducted by IT companies in Puducherry union territory. For this purpose the researchers a total of five IT companies namely, SBI Global Factors Ltd., Integra Software Solutions, Lumina Data Matics Global Services Ltd., Mediwave Digital and

Twilight IT Solutions. From which they selected 572 employees using simple random sampling method. Primary data were collected from the sample respondents through a well-structured questionnaire. For the purpose of analysing the primary data, the researchers applied the statistical tools of simple percentage, mean, standard deviation, coefficient of variation, cluster analysis, factor analysis and regression analysis as statistical tools.

RESULTS AND DISCUSSION

The primary aim of the paper is to study the perception of employees working in IT companies in Puducherry towards employees' recreational activities conducted by respective companies. Their perception level may vary based on frequency of participation in such employees' recreational activities,for this purpose the researcher also studied the frequency of participation by the employees on employees' recreational activities. These results are presented in the present section.

It is known from table 1 that the sample employees working in IT companies in Puducherry participated most frequently in the organisational recreation of "Meditation / Yoga", since it secured highest mean score among 17 organisational recreations (3.10 out of 4.00), about half of the respondents (46.6%) opined that they regularly participated in the activity and it was ranked first. Followed by, the sample employees also participated frequently in the organisational recreational activities of 'Dances', 'Craft / art competition', 'Board games', 'Sports events', 'Outdoor tournaments', 'Mehendi / tattoo', 'Karaoke' and 'Potluck lunches', since they also secured high mean values at 3.01, 2.98, 2.93, 2.89, 2.87, 2.86, 2.84 and 2.80 respectively and they were ranked 2nd, 3rd, 4th, 5th, 6th, 7th, 8th, and 9th respectively. The organisational recreational activity of 'Fun games' was found to be the least frequently participated by the respondents in the study area, since it secured lowest mean value (2.29) and it was ranked last (17th), followed by 'Picnic / tour', 'Quiz' and 'Office cookoff', they recorded lower mean values at 2.34, 2.41 and 2.61 respectively and they were ranked 16th, 15th and 14th respectively. The overall mean scores indicated that the frequency level of participation was high for musical and dance events in the studied companies, it secured high mean value at 2.84, outdoor events was found to be the least frequently participated organisational recreational activities in the study area (Mean: 2.72).

In order to analyse it, the researcher collected primary data to analyze the frequency of participation in various employees' recreation activities / events by the employees in selected IT companies located in Puducherry. For this purpose, the researcher encompassed 17 different types of recreation, with the findings presented in the tables above. In total, the researcher examined 17 types of recreational activities in which the employees participated. The frequency levels of participation of employees in the various recreational activities / events were categorized into four groups: 'Regularly', 'Occasionally', 'Rarely', and 'Never'. To further organize these results, the frequency levels of the various recreational activities were grouped into two categories: Frequently and Not Frequently. For this analysis, K-Means cluster analysis was employed. The results of this analysis are displayed in the following table.

The table 2 presents the final outcomes of the cluster analysis regarding the frequency levels of participation of employees in various recreational activities / events organized by IT companies within the study area. The respondents were divided into two distinct categories. The mean scores for cluster one and cluster two are 2.69 and 2.82, respectively. The highest mean score was observed in cluster one (2.82 out of 4.00), which was designated as indicating that the organisational recreational activities are participated by employees "Frequently." Conversely, cluster two exhibited a lower mean value, following cluster one (2.69 out of 4.00), and was classified as indicating that the employees of the sample companies participated in the organisational recreational activities "Not Frequently" in the study area.Table 3 gives the results of number of respondents fall under each cluster and their respective percentage.

Table 3 illustrates the results regarding the number of respondents in each cluster along with their corresponding percentage of the total concerning the frequency of participation of employees in various employees' recreational

activities / events organized by IT companies in the study area. It was noted that almost similar number of employees were categorised under two categories namely participated 'Frequently' and participated 'Not Frequently'. 50.70% of the respondents indicated that they participated in employees' recreational activities 'Not Frequently', while 49.30% of the respondents fell into the category of participating in organisational recreational activities in 'Frequently' category. According to the findings from the cluster analysis, the majority of sample respondents expressed that the IT companies in the Puducherry area that they participated in employees' recreational activities 'Not Frequently', but the percentage of the respondents fell under both the categories are similar. Therefore, sample employees working in IT companies in the Puducherry area participated in recreational activities organized by the company often with the objective of enhancing their work-life balance.

Perception of employees' recreational Activities

Participation in employees' recreational activities helps both employees and the management of the company. It helps the employees to upkeep their physical and mental health, it leads for improving work-life quality of employees. The same helps the management since, with good mental and physical health employees work efficiently and their productivity level increases. But it will be successful only when employees' recreational activities are conducted in efficient manner. It is mainly depend on employees, hence to improve OR activities, it is necessary to know the perception level of employees regarding OR activities. For this purpose the researcher identified a total of 24 variables related to OR activities in the sample companies. The number of variables are very high, hence in order to reduce it the researcher applied factor analysis. The outcomes of the communalities of the statements prior to and following the factor extraction are displayed in the subsequent Table. The initial communality, that is, before extraction, is considered to be 1. Nevertheless, after the factor extraction, the communality is contingent upon the amount of variance accessible for the analysis of the chosen variable. On an individual basis, 100 percent variance is available for the examination of the statements/variables. However, once the factors are extracted, the same variance is diminished in the process. Therefore, it is essential to evaluate the remaining variance available for analysis. The individual variances are illustrated in the following communalities. This represents the proportion of variance elucidated by the variables subsequent to extraction through factor analysis.

Table 4 shows that the variances of the variables were high and statistically significant. The results reveal that the calculated communalities for all variables exceed 0.5, indicating the model's good fit in the factor analysis. Higher communalities suggest a better fit, so all variables are suitable for analysis. The factor analysis employs Principal Component Analysis (PCA) to identify and estimate the eigenvalues of the principal components. After calculating these eigenvalues, they are ordered from highest to lowest. Following Kaiser's criterion, only factors with eigenvalues greater than 1 are retained, leading to a reduction in the number of factors as shown in the table below.

Table 5 presents the results of the factor analysis, showing Eigen values at both the initial stage and after applying the rotation method. The analysis focused on employees in IT companies in the study area and their perceptions of employees' recreational activities. The results indicated that 24 initial factors were condensed into 6 factors using the rotation method, each with an Eigen value greater than 1. These six factors accounted for 56.388% of the total variance of the included statements. This suggests that the explained variance is adequate, and the variables can be used for further analysis. To refine the components representing the 24 statements, orthogonal rotation (Varimax) was applied. The Rotated Component Matrix (RCM) displays the factor loadings for each variable, which represent the correlation between the variables and the factors. It is assumed that each variable should have a significant factor loading on only one factor and insignificant loadings on others. The detailed results, including correlations under the rotated matrix, are presented in Table 6.

Table 6 reveals that the results of perception of the respondents towards organisational recreational activities conducted in IT companies in Puducherry area. All the 24 factors were reduced into six factors by using factor analysis. The factors 1 to 5 were highly correlated with factor 1, hence they were grouped into one and they were labelled as "Benefits Attained". The factors 6 to 9 were highly correlated with factor 2, hence they were grouped into one and they were labelled as "Eagerness in Participation". The factors 10 to 12were highly correlated with factor 3,

hence they were grouped into one and they were labelled as "Facilities Available". The factors 13 to 16were highly correlated with factor 4, hence they were grouped into one and they were labelled as "Frequency and Timing of Organisational Recreation". The factors 17 to 21were highly correlated with factor 5, hence they were grouped into one and they were labelled as "Organizing Method". The factors 22 to 24were highly correlated with factor 6, hence they were grouped into one and they were labelled as "Suitability". Table 7 brings out the results of descriptive statistics of perception of employees on organisational recreational activities in the sample companies.

Table 7 shows that there was high positive perception by the respondents towards organisational recreational activities in the sample companies in the dimension of "Organising method", since it recorded highest mean value of 3.60 and it was ranked first, since the employees were highly impressed on the organizing methods of recreational activities conducted by the companies such as conducted systematically, interesting manner, safe way, with proper schedule and grand manner. The respondents also had positive perception in the dimensions of "Benefits Attained" and "Suitability", since their calculated mean values were found to be high at 3.47 and 3.40 respectively and they were ranked 2nd and 3rd respectively. It indicates that the employees in the sample companies opined that they attained benefits attending organisational recreational activities and the activities were designed were suitable for all age groups and all gender. The perception level of the respondents was lowest on the dimension of "Frequency and Timing of organizing organisational recreations", its mean value was lowest at 3.08 and it was ranked last (6th). The results of standard deviation and coefficient of variation indicated that there was lower level of deviation in perception level of the respondents from their respective mean values for all the dimensions of organisational recreational activities.

The frequency of participation in organisational activities may influence the perception level of the respondents towards various aspects of organisational recreational activities. With the aim of analysing the above, the researcher applied regression analysis assumed that the variables of frequency of participation in organisational recreational activities in the aspects of 'indoor events', 'musical and dance events' and 'outdoor events' are independent and the variable of 'perception on organisational recreational activities' as dependent variable. These results are presented below. It is known from table 8 that the calculated 'F' and 'P' values of testing the influence of frequency of participation in organisational recreational activities by employees and their perception on organisational recreational activities stood at 2.616 and 0.050 respectively, it shows that the model framed for the study is fit for further analysis. The calculated value of adjusted R square stood at 0.096, it indicates that the frequency of participation in organisational recreational activities explained the perception level at about 10%. Table 9 presents the results of regression analysis of the influence of frequency of participation in organisational recreational activities on perception of employees.

It is observed from table 9 that the frequency of participation in organisational recreational activities by the employees in the divisions of 'indoor events', 'musical and dance events' and 'outdoor events' are positively and significantly influenced the perception level of the respondents towards organisational recreational activities conducted in the sample IT companies in Puducherry, since their calculated 't' values under regression (2.616, 2.865 and 2.440 respectively) are statistically significant as shown by the results of their respective 'p' values (0.009, 0.002 and 0.015 respectively).

CONCLUSION

Organisational recreational activities are essential in IT companies as they enhance team bonding, encourage a healthy work-life balance, and elevate employee morale and productivity. These activities offer a necessary respite from the challenging and frequently stressful projects that IT professionals face daily. By participating in recreational activities such as team sports, outings, or wellness programs, employees can rejuvenate, mitigate burnout, and enhance their overall well-being. Furthermore, these activities contribute to a positive work atmosphere, facilitate better communication among team members, and fortify relationships, ultimately resulting in heightened

collaboration and creativity within the organization. In the rapidly evolving realm of IT, emphasizing organisational recreational activities can significantly influence employee satisfaction and retention rates. The researcher studied the frequency of participation in employees' recreational activities and perception on those activities and impact of frequency of participation on perception. The researcher found that the frequency level of participation was high for 'musical and dance events', and outdoor events was found to be the least frequently participated organisational recreational activities in the study area. High positive perception by the respondents was found towards organisational recreational activities in the sample companies in the dimension of "Organising method" followed by "Benefits Attained" and "Suitability". It was also evidenced that the frequency of participation in organisational recreational activities in the divisions of 'indoor events', 'musical and dance events' and 'outdoor events' are positively and significantly influenced the perception level of the respondents towards organisational recreational activities.

ABSTRACT

The pharmaceutical industry faces growing demand for analytical methods that are accurate, sustainable, and resource-efficient**.** Green Analytical Chemistry (GAC) and Smart Analytical Approaches (SAA) have emerged as key strategies to achieve these goals. This review outlines their principles, methodologies, and applications in pharmaceutical analysis—focusing on reducing solvent use, minimizing waste, employing miniaturized and automated systems, and integrating digital tools such as AI**,** ML**,** and PAT. The integration of green and smart technologies is reshaping analytical quality control, regulatory compliance, and sustainability. Additionally, the review emphasizes the role of green chemistry in minimizing hazardous chemical use, promoting recycling, protecting the environment, and supporting sustainable innovation in the pharmaceutical sector.

Keywords: Green Analytical Chemistry, Smart Analytical Approaches, Pharmaceutical Analysis, Sustainability, Process Analytical Technology, Chemometrics, AI in Pharma.

INTRODUCTION

"Green chemistry" is the practice of creating chemical reactions and end products that are safe for the environment. Chemical products are necessary to be made such that, after use, they may be broken down into environmentally acceptable parts. Green Chemistry is a comprehensive scientific approach aimed at designing chemical products and processes that minimize or eliminate the creation and use of hazardous substances harmful to humans, animals, and the environment. It considers a wide range of safety and environmental factors, including flammability, explosion risks, global climate impact, ozone depletion, and toxicological effects such as mutagenicity and carcinogenicity. Introduced in the 1990s by Paul Anastas and John Warner, the concept of Green Chemistry has since driven significant progress toward safer and more sustainable chemical practices. Growing concerns about environmental degradation affecting air, water, food, and agriculture—have emphasized the urgent need to adopt greener, more responsible methods of synthesis and production.

The application of Green Chemistry has already shown notable success. For instance, replacing chlorofluorocarbon-based insulating foams with eco-friendly alternatives has helped reduce ozone layer depletion, while advancements in energy production and the development of less toxic pesticides have lessened environmental harm. However, global efforts remain insufficient, and greater collective responsibility is required. As emphasized, individuals must view the Earth as their shared home—encouraging safer choices, reduced waste, and increased recycling to minimize chemical hazards. In India, for example, modern agricultural initiatives such as efficient irrigation and improved seed quality have enhanced productivity, yet the excessive use of fertilizers and pesticides has negatively impacted soil, air, and water quality. Therefore, it is essential to pursue sustainable development strategies that protect the environment. Ultimately, Green Chemistry seeks to achieve this balance by reducing the use and generation of toxic substances, ensuring a safer and more sustainable future [1,2].

Analytical chemistry plays a pivotal role in pharmaceutical research, development, and quality assurance. Traditional analytical methods, although robust, are often associated with high solvent usage, toxic reagents, and large energy consumption. These practices not only raise environmental concerns but also increase operational costs. The paradigm shift toward Green Analytical Chemistry (GAC) aims to design environmentally benign methods, while Smart Analytical Approaches (SAA) leverage digital tools, automation, and chemometrics to make analytical practices more efficient, predictive, and sustainable.

Principles of Green Chemistry

The chemical industry is now attempting to solve some of these difficulties by using the 12 Principles of Green Chemistry to be followed.

1. Prevention- The first concept of green chemistry is the principle of prevention, or the idea that preventing waste formation is ultimately less expensive and better for both people and the environment than treating and eradicating garbage after it has appeared [3].
2. Atom economy- It should be planned to include all materials utilized throughout the production process as much as possible into the finished product [4].
3. Less hazardous chemical syntheses- The Less Hazardous Chemical Synthesis promotes the development of synthetic techniques for the use and synthesis of compounds that are less or completely dangerous to human health and the environment, wherever this is possible. Many industrial processes may be made safer and more affordable by substituting biological enzymes for hazardous chemicals [5].
4. Design Benign Chemicals - Chemical goods and procedures should be made in a way that minimizes their toxicity, bioaccumulation, and biotransformation while being extremely selective in nature and affecting the required functions. It is a selective insecticide that exclusively kills wide leaf weeds for instance in 2, 4-D [6].
5. Safer Solvents and Auxiliaries- Avoid utilizing auxiliary chemicals, separation agents, or other cancer-causing substances. Solvents including acetone, benzene, and ether should be avoided since they are very flammable. As they offer health hazards, other substances like CCl_4, $CHCl_3$, and should be avoided.

6. Design for Energy Efficiency: - It is necessary or vital to build a chemical manufacturing process that consumes less energy to provide the intended outcome. carried out using a suitable catalyst at ambient pressure and temperature.
7. Use of Renewably Sourced Feed stocks- Whenever it is technically and economically feasible, use renewable feed stocks.
8. Reduce chemical derivatives- The use of blocking groups, protection / deprotection, and temporary alteration of physical/chemical processes are examples of unnecessary derivatization that should be reduced or avoided wherever feasible since they need extra reagents and can produce waste [7].
9. Catalyst: - Stoichiometric reagents are inferior than catalytic reagents. One of the most essential components of environmentally friendly chemistry is catalysis, which supports several green chemistry objectives including energy efficiency, less consumption of energy, improved yields, and achieving high selectivity with little waste utilizing biocatalysts. For its vital function, catalysis is known as the "foundation pillar of green chemistry" [8].
10. Design for Degradation: - Chemical goods should be made in such a way that they degrade into harmless by products at the conclusion of their usage or function and do not linger in the environment.
11. Real-time Analysis for Pollution Prevention- It is necessary to create analytical approaches that enable real-time, in-process monitoring and control of any negative consequences prior to the creation of dangerous chemicals.
12. Inherently Benign Chemistry for Accident Prevention: - To reduce or completely prevent the possibility of chemical accidents, such as explosions, fires, and smoke produced as a result of chemical release into the environment, chemical processes and products as well as their physical forms, such as solid, liquid, and gaseous form, are designed. Here also involved some hazardous substances are Corrosive, Flammable, Explosive, Reactive, Toxic. To avoid mishaps and injuries the taking after right steps should be taken; - Examined names and SDSs to memorize almost unsafe and required security safeguards. - Check for satisfactory ventilation. - Remove things from the work zone that seem touch off or respond with the unsafe materials.

Green Analytical Chemistry (GAC)

Principles of Green Analytical Chemistry

GAC extends the principles of Green Chemistry to analytical sciences. Core objectives include:
Minimization of hazardous solvents and reagents
Reduction of sample size and energy consumption
Application of renewable and biodegradable materials
Development of solvent-free or aqueous-based methods
Promotion of on-site, real-time monitoring to reduce laboratory waste

Green Analytical Techniques

Microscale and miniaturized methods: e.g., microextraction, microfluidics
Alternative solvents: ionic liquids, supercritical fluids, deep eutectic solvents
Direct analysis methods: solid-phase spectroscopy, portable devices
Waste reduction strategies: solvent recycling, solvent less sample preparation

Smart Analytical Approaches (SAA)

Concept of "Smart" Analysis

Smart approaches integrate automation, AI/ML algorithms, chemometrics, PAT, and digital monitoring tools to enhance efficiency and decision-making in pharmaceutical analysis.

Key Smart Analytical Tools

Process Analytical Technology (PAT): Real-time monitoring during manufacturing
Chemometrics: Data-driven modeling for multivariate analysis
Artificial Intelligence & Machine Learning: Prediction of analytical outcomes and optimization of methods
Miniaturized Lab-on-Chip Systems: Point-of-care and rapid testing

Automation & Robotics: High-throughput screening and reduced human error

Types of Green analytical chemistry

Method Development and Optimization:
Studies focusing on innovative analytical methods designed to minimize energy use and waste generation, including the application of green solvents and eco-friendly sample preparation techniques.

Sustainable Instrumentation:
Research evaluating the environmental impact of analytical instruments and proposing sustainable alternatives, modifications, or technologies to enhance eco-efficiency.

Waste Reduction in Analytical Processes:
Articles exploring strategies to reduce waste during analysis, such as process miniaturization, microextraction methods, and low-consumption analytical systems.

Recycling and Reuse of Materials:
Publications discussing the recovery, recycling, and reuse of solvents, reagents, and other materials commonly employed in analytical laboratories.

Use of Biodegradable Materials:
Reviews highlighting the integration of biodegradable or environmentally benign materials in analytical practices, including packaging, stationary phases, and consumables.

Case Studies:
Analyses compiling real-world examples of the successful application of green analytical techniques across diverse sectors such as pharmaceuticals, environmental monitoring, and food safety.

Comparative Studies:
Reviews comparing conventional analytical methods with greener alternatives, emphasizing improvements in efficiency, cost-effectiveness, and environmental sustainability.

Regulatory and Policy Frameworks:
Articles examining the role of legislation and policy in promoting environmentally responsible practices within analytical chemistry.

Future Trends and Challenges:
Publications forecasting emerging innovations, technologies, and challenges in the evolution of green analytical chemistry.

Green Metrics and Assessment Tools:
Studies proposing metrics, frameworks, or models for assessing the sustainability and environmental performance of analytical methods.

The significance of green analytical chemistry

Minimizes Waste: GAC promotes the adoption of energy saving devices and the production of as little waste as possible. For instance, analytical chemists are limited to analyzing the bare minimum of samples at the bare minimum of sample size.

Employs a safer Chemicals: GAC promotes the use of environmentally and human health-safe chemicals. Analytical chemists utilize GAC to assess the effectiveness and safety of both novel and well-established processes and products.

Widely Applicable Fields: GAC is utilized in forensic science, customized medicine, and food and beverage analysis. Several indicators of greenness that can be utilized to assess the effects of preparation of the dataset Preparing datasets for green analytical chemistry tests can be difficult and require analytical competence.

Professional assessment: Different methods could produce different outcomes.

The main objective of green analytical chemistry is to reduce or completely do away with the use of dangerous chemicals, reagents, and methods in analytical processes

Reduce the amount of chemicals you use: Reduce or cease utilizing solvents, reagents, additives, and preservatives altogether.

Cut down on the energy you use: Make use of energy-saving equipment

Handle waste: Take the proper care of analytical waste.

Boost safety Boost the operator's security.

Green Additives and Ingredients

Production of eco-friendly ingredients, the use of renewable resources in additives, and a decrease in the usage of hazardous chemicals. This covers the investigation of natural antioxidants, antibacterial agents, and safe preservatives for consumers as well as the surroundings. Green Chemistry for Water Conservation highlights the waste in food executing. This includes creating procedures that produce less byproducts and coming up with creative methods to reuse or recycle refuse. Reducing waste helps create a more enduring and efficient food production system.

Pharmaceutical

The application of green chemistry in the pharmaceutical sector not only supports sustainability goals, but additionally adds to the creation of economical and effective procedures for creating drugs. As the sector keeps changing, the incorporation of green Principles of chemistry probably has a growingly important part in forming the pharmaceutical manufacturing's future. [9] . Using greener solvents in place of conventional, dangerous ones either bio-based solvents or water. [10] Reaction condition optimization to lower vitality usage influence on the environment.

Green Developments

The majority of analytical chemistry research focuses on highly automated instrumental techniques the application of sophisticated detection techniques in order to satisfy society's growing need for comprehensive information about the environment, products, and processes, or the integration of several techniques for sample treatment and component separation. The reduction in energy and material usage that comes from integrating high throughput systems with numerous functions is Among the core ideas of green chemistry is. The use of novel materials, such as nanoparticles, microfilms, and micro assays, another fundamental idea of green chemistry is to drastically reduce waste and the size of sample required for analysis. Furthermore, the analysis of chemical data using computer and communication technologies, particularly in sensor related researches well as details Green Chemistry Another green chemistry principle is that handling green chemistry accepted manuscripts uses less energy and cuts down on the number of steps involved in chemical analysis. The "3R" approach, which stands for Reduction, Replacement, and Recycling, has led to the redesign of instrumental procedures as well as the broader introduction of substitute solvents. Additionally, it has a significant financial impact on control labs that perform a lot of analyses.

Pros of Green Chemistry

1. Green chemistry helps to create less waste in reality, green chemistry is a cutting-edge strategy for protecting both the environment and human health.
2. Long acknowledged to have a significant impact on the environment, energy usage and conservation.
3. Microwave heating in the solid state is a method that is being utilized to produce chemical changes fast, in contrast to how chemical modification has historically been carried out in liquid solutions.
4. Researchers may work in open vessels with chemical less radiation-aided reactions, which lowers the risk of high pressure and increases the possibility that such reactions may be scaled up.
5. The feasibility of microwave-assisted solvent-free synthesis has been demonstrated by several real modifications and the production of heterocyclic systems [11].

Cons of Green Chemistry

1. Designing chemical components and procedures that minimize or completely remove hazardous chemicals is the fundamental objective of green chemistry.
2. The conversion of an outdated, conventional product to a new, "green" product, as well as the creation of a new product and process, are among the major challenges in green chemistry, and these challenges are represented in time, prices, and a lack of knowledge in particular.
3. There are no known substitute chemical or raw material inputs, it is frequently difficult and extremely expensive, and there is also a lack of unity. about what is deemed safe.
4. Lack of green chemistry will result from the high implementation costs and lack of knowledge, since there will be no established option to apply chemical raw materials or different technologies for green processes. In addition, there is a lack of human capabilities [12].

Integration of Green and Smart Approaches

The convergence of GAC and SAA offers a synergistic framework:

Green + Smart Chromatography: Use of reduced mobile phase volumes with intelligent optimization algorithms

Eco-friendly, AI-optimized spectroscopy: NIR and Raman coupled with chemometrics

Digital twin models: Virtual simulation of analytical processes before physical experimentation

Smart sensors: Portable, low-waste, and real-time drug quality assessment tools

Applications in Pharmaceutical Sciences

Drug development: Rapid screening with minimal resource use

Quality control: Real-time, non-destructive analysis of raw materials and formulations

Stability testing: Predictive models for degradation kinetics with reduced experimental workload

Regulatory compliance: Alignment with ICH Q2(R2), USP, and EMA guidelines emphasizing eco-friendly practices

Challenges and Future Perspectives

Despite promising advances, challenges remain:

High initial investment in smart technologies

Limited availability of green solvents and materials

Regulatory adaptation to novel green-smart methods

Need for standardization in sustainability assessment metrics

Future directions include integrating AI-driven green method design, developing portable real-time devices, and adopting sustainability indices in pharmacopeial monographs.

CONCLUSION

Green and smart analytical approaches represent the future of pharmaceutical analysis, enabling the industry to balance analytical efficiency, sustainability, and regulatory compliance. By merging environmentally conscious practices with digital innovations, pharmaceutical sciences can move toward a cleaner, smarter, and more sustainable future.

ABSTRACT

Urban traffic congestion presents a significant challenge, contributing to elevated fuel consumption, carbon emissions, and increased travel times. The limitations of conventional fixed-time and rule-based traffic signal control systems, which cannot dynamically adapt to real-time traffic fluctuations, result in suboptimal efficiency. This paper addresses these issues by proposing a novel, AI-powered traffic signal control framework using deep reinforcement learning (DRL). We model the traffic signal optimization problem as a sequential decision-making task, where an autonomous agent learns optimal signal timings from real-time sensor and camera data. The framework employs advanced DRL algorithms, specifically Proximal Policy Optimization (PPO) and Deep Q-Networks (DQN), to minimize vehicle waiting times and maximize traffic flow efficiency. Our methodology is validated through simulations using SUMO (Simulation of Urban Mobility) on real-world traffic datasets. The results demonstrate that our DRL-based approach significantly outperforms traditional fixed-timing and actuated control systems, leading to reduced delays, increased throughput, and enhanced safety. Future work will explore decentralized multi-agent reinforcement learning for network-wide traffic management and address the practicalities of real-world deployment.

Keywords: Reinforcement learning, traffic signal optimization, deep reinforcement learning, urban mobility, smart cities, traffic management, SUMO, Proximal Policy Optimization (PPO), Deep Q-Networks (DQN).

INTRODUCTION

Traffic congestion is a major issue in modern cities, negatively impacting the quality of life, fuel consumption, economic productivity, and the environment. Conventional traffic management systems struggle to maintain smooth vehicle movement due to rapid growth in urban populations and car ownership. These systems, such as fixed-time or actuated control schemes, often cause bottlenecks and unnecessary stops because they cannot adapt to dynamic traffic patterns. Artificial intelligence (AI) offers a transformative solution by providing data-driven strategies that adapt traffic management in real-time. The objectives of this research are to: (1) design and evaluate AI-driven traffic signal control systems; (2) compare the performance of DRL-based methods with conventional approaches; (3) establish standardized performance metrics for urban mobility; and (4) examine deployment challenges in real-world smart city infrastructures.

Literature Review

AI-based traffic signal control has been studied extensively, with reinforcement learning (RL) and deep learning models showing significant promise. Garg et al. demonstrated that DRL can improve throughput and reduce congestion. Zhang et al. highlighted the robustness of RL under limited data scenarios. Haydari et al. proposed bounded RL models considering sustainability and fairness. Sú et al. introduced EMVLight, a multi-agent RL system prioritizing emergency vehicles. Guo et al. presented CoTV, which integrates RL with connected and automated vehicles (CAVs) for cooperative mobility improvements.

Despite these advances, gaps remain. Many studies focus only on vehicles, neglecting pedestrians and cyclists. DRL's black-box nature limits adoption due to lack of transparency. Additionally, standardized evaluation metrics are lacking, and most systems work only in simulation, with limited real-world validation. This research addresses these gaps by incorporating multimodal data, explainable AI methods, and broader testing across different environments.

RESEARCH METHODOLOGY

A. Research Design

The study employs a quantitative, experimental design, leveraging reinforcement learning to optimize traffic flow. Models including DQN, PPO, and A3C are trained and tested using real and simulated traffic data. Performance is measured against traditional traffic management approaches.

B. Data Collection

Data is sourced from (1) public datasets such as METR-LA and PeMS, (2) real-time APIs, (3) simulation tools like SUMO, and (4) sensor-based data from CCTV and connected vehicles.

C. Tools and Technologies

Python, TensorFlow, and PyTorch are used for model development. SUMO simulates traffic environments. Cloud platforms enable scalable training. Apache Spark supports large-scale data processing.

D. Experimental Setup

Performance is evaluated using congestion and reward functions. The RL reward function balances delay, emissions, and congestion:

$$R(t) = -\Sigma (w1 \cdot \Delta ti + w2 \cdot Ei + w3 \cdot Ci) \quad (1)$$

where Δti is delay, Ei is emissions, Ci is congestion, and $w1$, $w2$, $w3$ are weights.

RESULTS AND FINDINGS

Experiments show PPO significantly outperforms rule-based and adaptive methods:
-Average delay reduced by 60% (to 30 seconds).
-Throughput increased to 92%.
-CO2 emissions reduced by 25%.
-Fairness score of 0.95 achieved, ensuring inclusivity.
- Scalability demonstrated across urban, suburban, and rural networks.

DISCUSSION

Results confirm PPO's stability and adaptability compared to DQN and traditional methods. Importantly, fairness and inclusivity metrics demonstrate improved equity for all road users. The scalability of PPO across environments makes it a strong candidate for real-world deployment. However, explainability and simulation reliance remain challenges for adoption.

CONCLUSION

This research demonstrates that DRL-based traffic signal control, especially PPO, provides substantial improvements in congestion mitigation, sustainability, and inclusivity. Key contributions include establishing standardized evaluation metrics, incorporating multimodal data, and demonstrating scalability. Future work will focus on hybrid AI models, V2X-based large-scale systems, and explainability for real-world adoption.

ABSTRACT

Heavy metals are a class of elements characterized by high atomic number and higher density than water. These are the naturally occurring metals in the Earth's crust. They are available in a low concentration and with a density of at least 5g/cm^3. Examples of heavy metals are Arsenic (Ar), Cadmium (Cd), Molybdenum(Mb), Lead(Pb), Mercury(Hg), Copper(Cu), Iron(Fe), etc. Despite the presence of heavy metals in trace elements, exposure of humans to heavy metals causes hazardous effects on human health. Heavy metals affect the environment adversely through various sources like industrial processes, (such as refineries, nuclear power stations, textiles, etc.) waste disposal, vehicle emissions, and agricultural runoff. The exposure of humans to heavy metals leads to toxicity due to the interaction of metal ions with the cellular components such as DNA and nuclear proteins causing DNA and mitochondrial damage, disruption of metabolism, and finally leading to tumor or apoptosis and generation of reactive oxygen species. Recently emerged studies described one of the mechanisms for alleviating heavy metal toxicity introducing chelators. Plants, medicinal herbs, and other bioactive components found in plants act as the best chelators. A few medicinal plants such as *Phyllanthus emblica, Boerhavia diffusa, Nigella sativa, Portulaca oleracea,* etc., are used to treat heavy metal toxicity. In the present study, we reviewed the bioactive components and other medicinal herbs used to ameliorate the toxicity of various heavy metals.

Keywords Heavy metal toxicity, Medicinal herbs, *Boerhavia diffusa,* Nephrotoxoicity.

INTRODUCTION

Heavy metals are chemical elements that have a specific gravity (a density measurement relative to an equivalent volume of water) that is five times greater than that of water (1-4C°). Physical considerations determine the presence of heavy metals.(phase interaction, adsorption, temperature), and chemical elements(kinetics, solubility of fats) and biological elements (human Trophism) [21]. Renal toxicity can result from therapeutic, unintentional, or occupational exposure to a number of metals. The elements arsenic, copper, lead, lithium, cobalt, cadmium, mercury, and platinum are the most frequently implicated with kidney poisoning. Since these trace elements are crucial components and co-factors in numerous biochemical cellular pathways, such as the creation of proteins and nucleic acids and enzymatic reactions, small amounts of them are required for optimal health. Agriculture and industrial processes like the manufacturing of pesticides, batteries, alloys, and textile dyes are major sources of heavy metal pollution, but natural events like earthquakes and volcanic eruptions have also been shown to play a major role in environmental contamination [4].

Types of heavy metals

Arsenic, Lead, Copper, Mercury, Cadmium, Lithium, Platinum, Aluminium, Uranium,Iron.

Mechanism of heavy metal toxicity

The overall mechanism of heavy metal poisoning involves cellular disruption of metabolic equilibrium. The body's overabundance of heavy metals causes them to deposit and accumulate in different tissues. The metallic deposits interfere with mitochondrial, metabolic, and enzymatic processes, impairing biological function [51]. Nuclear proteins and DNA are two examples of biological components that metallic ions may interact with, causing structural alterations and apoptosis [6]. Laboratory research highlights that oxidative stress and reactive oxygen species play a key role in the toxic and cancer-causing effects of heavy metals like arsenic, cadmium, chromium, lead, and mercury. These metals are highly toxic to the body, even at low concentrations, and can damage multiple organ systems, significantly affecting overall health [20].

Causes of heavy metal toxicity

Heavy metals have a number of immediate and long-term harmful impacts on various human organs. Complications of heavy metals' harmful effects include cancer, vascular damage, skin lesions, immune system malfunction, neurological diseases, intestine and renal dysfunction, and birth abnormalities [18]. Severe side effects such renal failure, bloody diarrhea and abdominal colic pain can be brought on by high doses of heavy metal exposure, especially lead and mercury [5]. Low-dose exposure to heavy metals poses a subtle and often unnoticed risk unless it occurs repeatedly over time. In such cases, the resulting complications may reveal the exposure, including neuropsychiatric disorders like fatigue, anxiety, and adverse effects on children's intelligence quotient (IQ) and cognitive development [35]. The toxicity and carcinogenic effects of heavy metals are influenced by the exposure dose. High doses can cause significant adverse reactions in both humans and animals, including DNA damage and neuropsychiatric disorders [24].

Arsenic

Arsenic is a potent sulfhydryl-reactive chemical that can bind to and cross-link cellular proteins, altering multiple cellular pathways such as growth factor expression, cell cycle checkpoint protein suppression, apoptosis promotion, DNA repair inhibition, decreased immune surveillance, and increased oxidative stress. These changes in cellular pathways play important roles in a variety of human diseases, including carcinogenesis, genotoxicity, diabetes, hypertension, weight loss, and cardiovascular and neurological disorders. Furthermore, there is growing evidence that arsenic exposure causes the production of reactive oxygen species (ROS), which promotes tumor growth [47]. Cell death induced by arsenic trioxide may occur through various mechanisms. These include the activation of caspase enzymes, increased production of reactive oxygen species (ROS), opening of mitochondrial permeability transition pores, inhibition of the apoptosis-regulating Ras/mitogen-activated protein kinase pathway, and increased

movement of promyelocytic leukemia protein to nuclear bodies [46]. *Phyllanthus emblica* is an excellent source of vitamin C and minerals, as well as phenolic components such tannins, phyllembelic acid, phyllembelin, rutin, curcuminoids emblicol, emblicanin A and B, gallic acid, and ellagic acid. The effects of *P. emblica* include immunomodulatory, hepatoprotective, anti-diabetic neuroprotective, anti-inflammatory, antioxidant, and anti-cancer properties [43]. The P. emblica extract is evident in preventing the arsenic-mediated reduction in body weight gain and arsenic-mediated organ enlargement [47].

Lead

Lead (Pb) is a hazardous heavy metal in the environment that poses a significant risk to human health globally. It appears in various ways and sources including food and air pollution. it is highly hazardous to multiple organs, including the testes, brain, kidney, liver, and hematological tissues. Lead-contaminated food and water are absorbed through the duodenum via divalent metal transporter 1 and leached into the bloodstream. Oxidative stress, caused by an imbalance between oxidants and antioxidants, is a major mechanism behind lead-induced damage. Damage to the systems caused by an overabundance of reactive oxygen species (ROS) leads to the impairment of mitochondria and cell.

Excessive ROS production caused by lead can impair mitochondria and cells. Plants contain flavonoids and polyphenols, which are known to have antioxidant properties. A plant rich in flavonoids, Paederia foetida Linn., is used as a traditional remedy for diabetes, rheumatoid arthritis, diarrhoea, and asthma.The current investigation revealed that rats exposed to lead had considerably higher AST and ALT levels than the control group, indicating lead-mediated liver injury. Furthermore, in rats exposed to lead, neutrophil infiltration was seen in the vicinity of the periportal regions of liver tissue. Remarkably, PFE treatment at 100, 500 and 1,000 mg/kg BW restored or prevented the liver tissue's histopathology and reduced ALT and AST. These findings imply that PFE can guard against hepatic damage and stop the changes in the liver brought on by the harmful effects of exposure to lead acetate [31].

Copper

Several membrane proteins and smaller soluble peptides make up a functionally integrated system that regulates cellular Cu homeostasis and is essential for the transport and metabolism of Cu. Integral membrane proteins that create the channels that choose Cu ions for passage seem to be responsible for inward transport across the plasma membrane. The Menkes and Wilson disease genes, respectively, produce the membrane-bound Cu-transporting ATPase enzymes ATP7A and ATP7B, which catalyze the ATP-dependent transfer of Cu to internal compartments or the expulsion of Cu from the cell. Together, ATP7A and ATP7B function with a group of smaller peptides known as copper chaperones, which either exchange copper at the ATPase sites or directly incorporate copper into the structure of Cu-dependent enzymes including cytochrome c oxidase and Cu, Zn superoxide dismutase. These processes are activated during normal Cu metabolism or in response to a large Cu inflow [17]. Ocimum sanctum given orally decreased the concentration of iron in the serum and tissues of CuSO4-toxic rats while also lowering ferritin, which carries iron. Atomic absorption spectroscopy revealed that the CuSO4-injected rats had higher copper concentrations in the examined organs, such as the liver and kidneys, which was consistent with prior research. Through an unidentified method, giving Ocimum sanctum orally for 30 days caused the copper level of CuSO4-treated rats to drop towards the normal level [50].

Mercury

Any form of mercury is harmful, leading to oxidative stress and antioxidant system depletion. The most hazardous heavy metal that may easily permeate biological membranes and form organomercury compounds with proteins is mercuric chloride ($HgCl_2$). Through the non-enzymatic transfer of a methyl group from methylcobalamin to a mercuric ion, bacteria can methylate inorganic mercury to produce methylmercury compounds, which can accumulate in target organs, primarily the kidneys and brain, and cause harmful effects. Chronic exposure to mercury in the environment and/or at work may cause neurological, hepatic, hematologic, immunologic, and reproductive problems in both people and animals. Since the liver and kidney are engaged in detoxification and excretion, the primary hazardous species in these organs is the mercuric ion, Hg^{2+}.Renal failure is caused by the

uptake, buildup, and toxicity of inorganic mercury in the kidneys, which is linked to its binding to endogenous molecules that contain thiols. Oxidative stress, mitochondrial depolarization, and likely uncoupling brought on by the buildup of $HgCl_2$ in the liver resulted in ATP depletion, bleb development, and eventually cell death. Because it improves the mobilization and excretion of metallic cations, chelation of the metals is a useful treatment for metal-induced toxicity. Ginger, or *Zingiber officinale*, is a member of the Zingiberaceae family and is used medicinally. The pharmacological and biological properties of ginger extract are numerous. Its abundant antioxidant qualities, which support its ability to scavenge free radicals—a property well-suited for metal chelation—have been found to operate as an antitoxic agent. Research has demonstrated that ginger and its active compound, 6-gingerol, can regulate key molecules involved in cell signaling pathways, including nuclear factor-kappa B (NF-κB), activator protein-1 (AP-1), growth factors, chemokines, mitogen-activated protein kinase (MAPK), p53, cyclooxygenase-2 (COX-2), and inducible nitric oxide synthase (iNOS). As a safe, affordable dietary ingredient, *Zingiber officinale* Rosc. extract and 6-gingerol show potential for mitigating mercuric chloride toxicity by reducing oxidative stress and boosting antioxidant enzyme activity, according to the findings of this study [30].

Cadmium

Cadmium (Cd), an element with the atomic number 48, atomic mass number 112, melting point 321 °C, boiling point 765 °C, and a silvery white, bluish tint, is soft, ductile, glossy, and electropositive. It is extremely deadly and has no flavor or smell. There are eight stable isotopes of cadmium 106 Cd, 108 Cd, 110 Cd, 111Cd, 112Cd, 113Cd, 114Cd, and 116Cd. The isotopes 112 Cd and 114 Cd are the most prevalent. Apoptosis, differentiation, and cell proliferation are all impacted by cadmium. Apoptosis induction, reaction oxygen species (ROS) production, and DNA repair mechanisms are all impacted by these activities. When cadmium is present in small amounts, it can impair oxidative phosphorylation and cellular respiration by binding to the mitochondria. Cadmium alters signal transduction pathways by inhibiting calcium channels, raising cytosolic free calcium levels in different cell types, and causing the synthesis of inositol polyphosphate. At lower concentrations, cadmium binds to proteins within the range of 1 to 100 μM, interfering with DNA repair and degradation. It also stimulates the release of cytokines and activates proto-oncogenes such as c-fos, c-jun, and c-myc. Additionally, cadmium triggers the expression of a variety of genes, including metallothioneins, heme oxygenases, glutathione transferases, heat-shock proteins, acute-phase reactants, and DNA polymerase [56].

Portulaca oleracea extract was found to have hepatoprotective against cadmium toxicity.The liver functions of the rats treated with *P. oleracea* alone did not significantly change. Hepatic enzymes were significantly restored, indicating that purslane extract contributes to hepato-protection against Cd poisoning. The active ingredients in P. oleracea, including as flavonoids, polyphenols, and alkaloids, may be responsible for its beneficial effects. According to reports, polyphenols have the ability to stabilise membranes by preventing the production of ROS brought on by Cd and preserving the structural integrity of cell membranes [48].

Lithium

Lithium is frequently used to treat refractory depressive disorders, bipolar disorders, and cluster headaches as a long-term preventative measure. The therapeutic index is limited. Chronic intoxication from lithium is more prevalent. Lithium gradually builds up, typically as a result of reduced excretion. Lithium toxicity results in fluid depletion, medication interactions, reduced renal function, and coexisting conditions including cirrhosis or congestive heart failure. Through its inhibition of inositol synthesis, effects on the protein kinase C signaling pathway, and inhibition of glycogen synthase kinase 3 (GSK3), lithium influences a variety of cellular processes. Lithium-induced organ damage can be identified and treated early to save lives and significantly lower morbidity. Lipid levels may rise due to elevated production and declined consumption of lithium. $Li2CO_3$ increases the manufacture and esterification of cholesterol, which can lead to the production of free radicals and the buildup of cholesterol within cells. One well-known toxicity concern associated with $Li2CO_3$ is the substantial rise in the liver's rate of TG, PL, and FFA synthesis. In animal models, lithium toxicity is a state of elevated oxidative stress, primarily demonstrated by increased lipid peroxidation (LPO) or indirect indications of decreased antioxidant reserves, such as SOD and catalase enzymes.

In renal injury, apoptotic cell death has also been linked to ROS, oxidative DNA damage, and DNA fragmentation. Disturbances in NO, a crucial modulator of signaling processes connected to apoptotic cell death, are indicative of the cytotoxic effects of Li 2CO3 on liver tissue. By inhibiting DNA fragmentation, having antioxidant properties that counteract free radicals, and reducing harmful alterations in key organs, Solanum trilobatum L. reduces the toxicity of lithium-induced organ damage in rats [58].

Platinum

Platinum-based drugs like oxaliplatin and cisplatin are utilized for platinum toxicity**.** The most prevalent antineoplastic DNA alkylating agent used to treat a range of malignancies is cisplatin (cis-diamine dichloro platinum II). Cisplatin has been documented to induce renal tubule cell death, which can be detected by decreased glutathione (GSH) levels and elevated blood urea nitrogen (BUN), serum creatinine, and malondialdehyde (MDA) levels, all of which point to rapid peroxidative procedures. Furthermore, it is known that reactive oxygen species (ROS) interact with several macromolecules in the cellular membrane, including polyunsaturated fatty acids, to induce tissue damage. Endogenous antioxidants like GSH and superoxide dismutase (SOD) directly eliminate ROS, which are produced endogenously in renal cells. Rubus coreanus revealed potent antioxidant properties. Indeed, it has been demonstrated that several saponins, including the 19a-hydroxyursane-type triterpenoids and their glycosides that were separated from Rubus sp., exhibit antioxidant properties. Severe nephropathy including acute renal failure is caused by cisplatin-induced nephrotoxicity. This condition is linked to the loss of renal functions, such as significant decreases in glomerular filtration and creatinine clearance, as well as elevated BUN and blood creatinine levels. Serum creatinine and BUN levels are helpful indicators of kidney function because they have a strong correlation with renal function. By monitoring the decrease of BUN and serum creatinine levels, this study demonstrates that 23-HTA greatly reduces cisplatin-induced nephrotoxicity [53].

Aluminium

Aluminum is one of the most abundant elements in the Earth's crust, making up about 8% of all minerals. It exists naturally in many plant and animal tissues, as well as in water, in its ionic form as a trivalent cation. Despite its abundance, aluminum can be harmful due to its ability to generate reactive free radicals. These radicals can overwhelm the body's antioxidant defenses, leading to oxidative stress, which damages cells. Aluminum-induced oxidative stress has been linked to harmful effects on the brain, kidneys, liver, bones, and blood. Nigella sativa (black seed) has shown protective effects against oxidative damage caused by conditions like renal ischemia-reperfusion and toxin-induced damage to the kidneys and liver. Similarly, *Allium sativum* (garlic) is known for its broad range of health benefits, including antibacterial, antifungal, anti-inflammatory, and antioxidant properties. Garlic contains compounds like flavonoids, polyphenols, and tannins, which help boost antioxidant activity, enhance cellular defenses, and neutralize reactive oxygen species (ROS). In a study, histopathological analysis showed that key liver structures, such as the hepatic artery, portal vein, bile duct, and central veins, were well-preserved in groups treated with 5% Nigella sativa, 5% *Allium sativum*, their combination, or in the control group. No significant differences were observed in creatinine levels between the control group and the groups receiving 5% Nigella sativa, 5% *Allium sativum*, or their combination over four and eight weeks. Additionally, the combination of the two plants (2.5% each) maintained creatinine levels comparable to the control group. Regarding liver function, aluminum-treated rats (1,600 ppm) showed significantly higher levels of liver enzymes (AST and ALT) at four and eight weeks. However, treatments with *Nigella sativa* and *Allium sativum* reduced these elevated enzyme levels, suggesting improved liver function. The study demonstrated that supplementation with *Nigella sativa* and *Allium sativum* could mitigate aluminum's harmful effects and help restore normal kidney, liver, and testicular functions in albino rats. These plants were effective when used both during and after aluminum exposure [1].

Uranium

Uranium is unique in that it is poisonous both chemically because of its metal characteristics and radiologically because it emits alpha radiation. On the other hand, the radionuclide's chemical toxicity was thought to be the main factor in both natural and depleted uranium [51].

Uranium is a radioactive element belonging to the actinide group that emits alpha particles. Of all the naturally occurring elements, it is the heaviest. The human body absorbs uranium from the environment through the consumption of food and beverages as well as through the breathing of dust particles or aerosols that contain uranium. Uranium exposure can be harmful chemically and radiologically. Chromosome aberrations (CAs), DNA damage, mutagenicity, cancer, and neurological disorders are induced by uranium. The symptoms of early-stage Alzheimer's disease, vascular dementia, peripheral claudication, vertigo, heart illness, eye disorders, chronic cerebral insufficiency, brain trauma accidents, dementia, and tinnitus of vascular origin are most commonly treated with *Ginkgo biloba* leaf extract. Ginkgo leaf preserves the permeability and integrity of cell barriers by preventing membrane lipid peroxidation. Abnormal metaphases (AM) and CAs were induced in mice treated with uranium. As anticipated, mice given a 5 mg/kg b.wt dosage of uranium showed a significant frequency of AM and CAs overall compared to the control and GB-treated groups ($P<0.05$). Additionally, there was a large drop in MI, which Duncan's test indicated was statistically significant. However, mice pretreated with GB showed a significant decrease in AM and CA frequencies prior to uranium administration at a dose of 5 mg/kg b.wt. The quantity demonstrated a propensity to decline in mice administered 50 and 150 mg/kg b.wt dosages of GB in contrast to the group treated with uranium alone. This reduction for fractures, fragments, acentrics, and AM was at least two times that of the uranium group in a 150 mg/kg b.wt dose of *Ginkgo biloba*. Furthermore, GB treatment groups' MI data showed an upward trend. Prior to uranium exposure, mice treated with GB showed a substantial decrease in the frequency of AM and CAs. When comparable studies are taken into account, our findings closely match data that has already been published. Scientists have demonstrated that uranium is carcinogenic and results in sister-chromatid exchanges, CAs, DNA damage, genetic mutations, and MN development both in vivo and in vitro [57].

Iron

These metabolic processes are distorted when there is hepatic injury, which can occasionally lead to major health issues. Since the liver is involved in absorbing and storing excessive amounts of iron, hepatotoxicity is the most frequent finding in patients with iron overload. All mammalian cells require iron, the most prevalent transition metal, to develop and survive. Cells always maintain an ideal level of iron to balance toxicity and essentiality, but occasionally this balance is upset, leading to iron-overloaded toxicity. This most likely occurs by the production of reactive oxygen species, such as extremely reactive hydroxyl radicals, which can cause damage to different biomolecules and result in oxidative stress, through Haber-Weiss processes. This causes oxidative damage to lipids, proteins, and nucleic acids, which in turn causes several human disorders, including hepatocellular necrosis. The most significant representatives that provide alleviation from hepatic disorders are phytoconstituents, such as flavonoids and phenolics. The majority of them have been shown to be potent antioxidants, with iron chelation playing a key role in their antioxidant activity. Research on plant-based crude medications with antioxidant properties has taken precedence over studies on *Nerium indicum's* hepatoprotective properties. When iron-dextran was administered intraperitoneally to mice, iron-overloaded circumstances were created. Intraperitoneal iron-dextran injection mimicked hemochromatosis and resulted in iron overload in the liver and serum by avoiding a direct disruption of plant extract on intestinal iron absorption. Serum levels of ASAT, ALAT, bilirubin and ALP rise as a result of cellular enzymes leaking into the bloodstream due to iron-overloaded liver injury. Serum levels of ALAT (196%), ASAT (148%), ALP (300%), and bilirubin (116%) were significantly elevated after iron-dextran treatment, indicating severe acute liver injury in mice. NIME's hepatoprotective action was demonstrated by the considerable restoration of these enzyme and bilirubin levels [23].

CONCLUSION

Heavy metal toxicity has emerged as a rising concern recently. Heavy metals are widely distributed in industries, agriculture, medicine, and technology. Even lower doses of heavy metals can potentially destroy organs and lead to death. Apparently, heavy metals also cause environmental contamination. These elements when inhaled from the atmosphere lead to various conditions such as cardiovascular diseases, neurological diseases, nephrotoxicity, hepatotoxicity, and other morbid conditions. We assessed several medicinal herbs in this study as potential

therapeutic agents, that interact with the metal ions leading to chelation. These chelating agents decrease the bioavailability and gastrointestinal absorption of the heavy metals. According to traditional medical systems like Ayurveda, medicinal herbs have an extensive spectrum of therapeutic applications. The propaganda for choosing medicinal herbs for the treatment is that they are easily available, bioactive and phytochemical components can be isolated for the targeted chelation of the metal ion, with lesser occurrence of adverse reactions. Furthermore, these medicinal plants can be used in various parts of the research on heavy metal toxicity. This study facilitates the evaluation of the toxicity and lethal consequences caused by heavy metals. Research on the usage of medicinal plants can be further developed in the future, which will contribute to clarifying their benefits over chemically synthesized drugs. Their ability to reduce oxidative stress, enhancing detoxification while causing lesser side effects enables them in managing the toxic effects of heavy metals. Hence, phytochemicals can provide a promising complementary approach to treating heavy metal-induced toxicity.

Table 1. Medicinal plants and their constituents used for alleviation of various heavy metal toxicities

S. no	Type of heavy metal	Toxicity caused by the heavy metal	Mechanism of action	Parameter	Animal model	Plants used for treatment	Chemical Constituents	References
1.	Arsenic	Reactive oxygen species (ROS) generate oxidative stress, which raises hemeoxygenase -1,MAPK, Cyt-P450, and JNK levels and induces lipid peroxidation, cellular damage, and apoptosis.	Arsenic-induced oxidative stress raises HO-1 and MAPK expression, which causes renal toxicity by modulating several transcription factors, including Elk-1, activator protein-1 (AP-1), and activating transcription factor-2 (ATF-2).	Decrease in body weight	Male swiss albino mice Osborne-Mendel rats Young beagle dogs	*Phyllanthus emblica*	Ellagic acid Quercetin Gallic acid Chebulinic acid	Parrish AR, Zheng XH,et al.,1999[41] Sasaki A, Oshima Y,et al.,2007.[46] Prananda AT, Dalimunthe A,et al.,2023[43]
2.	Lead	Lungs dysfunction, CNS injury, Hematological changes leading to anemia, liver damage,Cardiovascular dysfunction, Reduced pulmonary function, and chronic tubuloi nterstitial	Elevation in the levels of ET-1, EPO and NO. Inhibition in the heme biosynthesis by inhibiting the delta-ALAD and ferrochelatase. Increased production of inflammatory cytokines	Significant elevation in the levels of ALT, AST, Blood urea nitrogen (BUN)	Male wistar rats	*Paederia foetida* Linn.	Paederine a Paederine b Asperuloside Scandoside Paederoside	Strużyńska L, Dąbrowska-Bouta B,et al.,2007[55] Dongre NN, Suryakar AN,et al.,2011[15] Wang J, Zhu H,et al.,2013[59] Boskabady MH,

		nephritis.	TNF-α, IL-1β and IL-6.					Tabatabai SA,et al.,2016[7] Khamphaya T, Pouyfung P,et al.,2022[31]
3.	Copper	Rhabdomyolysis, intravascular hemolysis, Hepatic necrosis, Cardiac and renal failure, Encephalopathy, methemoglobinemia	Copper being an oxidising agent, reduces itself and binds to the intracellular sulfhydral groups and inactivates glucose-6-phosphate dehyrogenase and glutathione reductase. Interaction with superoxide anions and hydrogen peroxide leads to produce highly reactive and toxic hydroxyl radicals.	Increase in the activity of superoxide dismutase (SOD), Catalase (CAT), Glutathione peroxidase (GPx)	Male wistar albino rats	*Ocimum sanctum*	Orientin Andvicenin Cirsilineon Circinaritin Isothymusin	Harris ED.,2000[27] Pal A, Prasad R.,2016[40] SHYAMALA AC, DEVAKI T.,1996.[50] Saravu K, Jose J,et al.,2007.[45]
4.	Mercury	Renal dysfunction CNS injuries Gastrointestinal ulcerations	Production of Reactive oxygen species (ROS) Inhibition of Glutathione peroxidase Reduction in aquaporins mRNA	Increase in the levels of enzymes AST, ALT, SALP, LDH. Reversal in the increased levels of ALP,	Male sprague dawley rats Male wistar rats	*Zingiber officinalis* *Boerhavia diffusa* (Punarnava)	6-gingerol Punarnavine Boeravinone A Boeravinone-F β-sitosterol-	Cheng J. P., Wang W. H.,et al.,2006[11] Bottino C., Vázquez M.,et al.,2016.[8] Chen R., Xu Y., Xu C.,et al.,2019.[10] Zhang C., Gan C.,et al.,2020[62] Joshi D, Srivastav

				AST, ALT, LDH, LPO, Urea and Creatinine.			β-D-glucoside Quercetin Kaempferol	SK,et al.,2017.[30] Shivananjappa M.,2021[49] Nayak P, Thirunavoukkarasu M.,2016.[37]
5.	Cadmium	By inducing ROS and oxidative stress, Renal damage , calcium loss, proteinuria and tubular lesion.	By binding itself to the mitochondria, cadmium can inhibit oxidative phosphorylation and cellular respiration at low concentrations. Its toxicity includes reduced glutathione (GSH) depletion, protein binding of sulfhydryl groups, and increased reactive oxygen generation (ROS), including hydrogen peroxide, superoxide ions, as well as hydroxyl radicals	Reversal in the elevated levels of ALT, AST, ALP, Total protein, Urea, Creatinine, Triglyceride and Cholesterol.	Sprague dawley rats	*Portulucaoleracae*	Oleracein A Oleracein B Catechin Epicatechin Quercetin-O-hexoside isomer Kaempferol	Patrick L,2003[42] Filipic M.,2012[19] Yuan G., Dai S.,et al.,2014[61] Haribabu TE, Sudha PN,2011[26] Arini A, Feurtet-Mazel A, et al.,2012[3] Seif MM, Madboli AN,et al.,2019[48] Fernández-Poyatos MD, Llorent-Martínez EJ,et al.,2021[18]
6.	Lithium	Polyuria; potentially results in irreversible damage, interfering with the tubular	Inhibition of cyclic-adenosine monophosphate (cAMP), Decreased sodium	Elevation in total lipid profile, free cholesterol in	Male swiss albino wistar rats	*Solanum trilobatum*	Solanosine	Hestbech J, Hanson HE,et al.,1977[29] Haddad LM, Shannon MW,et

		function leading to interstitial nephritis.	reabsorption and GFR leading to nephrotoxicity	blood, phospholipids, triglycerides and fatty acid content in blood.				al.,1998[25] Ahmad M, Elnakady Y,et al.,2011[2] Vijaimohan K, Devi CS,et al.,2010[58] Mamun-or-Rashid AN, Hossain MS,et al .,2014[34]
7.	Platinum	Acute kidney injury, Fanconi-like syndrome, Distal renal tubular acidosis, Chronic renal failure, Renal salt wasting	Cisplatin stimulates tubular cells to produce TNF-α, which sets off an intense inflammatory response and further destroys tubular cells. Cisplatin may potentially harm the renal vasculature, which results in ischemia tubular cell death and a drop in GFR.	Significant decrease in the levels of CAT, SOD, GPx, BUN and serum creatinine.	Sprague dawley rats	*Rubus coreanus*	23-hydroxytormentic acid	Pabla N, Dong Z et al.,2008[39] Nacher-Soler G, Lenglet S,et.al,2021[36] Sohn SI, Rim HK, et.al,2011[53]
8.	Aluminium	Memory Loss, Tremors, Reduced GFR, Acute renal glomerulonephritis, Alteration in the levels of urea, uric acid, creatinine, Obesity, Liver Steatosis, Type 2 Diabetes.	By elevating the oxidative stress and lipid peroxidation Changing the renal tubular p-aminohippuric acid transport. By impairing the Na+/H2O balance By inhibiting the Na+/K+/ATPase	Significant decrease in total proteinnn percentage, serum albumin, increase in ALT and AST levels.	Male albino rats	*Nigella sativa*	p-cymene carvacrol thymohydroquinone α-pinene β-pinene γ-terpinene	Ng CH, Yahaya SN, Majid A.et al.,2017[38] Skejić D., Boko I.,et al.,2015[52] Abdel Ghfar SS, Ali ME,et al.,2022[1] Kumar A, Dogra S,et al.,2009[32] Sahak MK, Kabir N,et

			pump action.					al.,2016[44]
9.	Uranium	Proximal tubular function alters in response to rising calcium fractional excretion. Elevation in ALT and AST levels, which signifies a disruption in the liver function.	Liver detoxification process is altered using xenobiotic-induced metabolizing enzymes, including GSTA2 and UGT2B1\	Significant induction of chromosomal aberrations, abnormal metaphase formation in bone marrow cells.	male Mus musculus var. albino mice	*Gingko biloba*	Quercetin Kaempferol Isorhamnetin	Kurttio P, Auvinen A,et al.,2002[33] Yapar K, Cavusoglu K,et al.,2010[60] Dublineau, M. Souidi,et al.,2014[16] Domingo JL, Llobet JM,et al.,1987[14]
10.	Iron	Vomiting, Diarrhea with intestinal blood loss, induced by hemorrhagic necrosis, Ulceration of upper intestine, Capillary leakage with loss of interstitial fluid, Poor cerebral perfusion, Metabolic acidosis, Severe hypovolemia.	Alteration in transport of solute and ions due to modification in the mitochondrial membranes by lipid peroxidation. Free radical oxidation of polyunsaturated fatty acids produces hydroperoxidic products, they induce Ca2+ release from the mitochondria leading to generation of oxidative stress.	Elevation in the levels of ALT, AST, ALP and Bilirubin.	Male swiss albino mice	*Nerium indicum*	Resepine Neridorin Karabin	Hershko C.,2007[28] Stein M, Blayney D,et al.,1974[54] Ghate NB, Chaudhuri D,et al.,2015[23]

ABSTRACT

While documenting the bryophytes of Ponmudi Hills on the Western Ghats of Kerala, the moss *Leucoloma tenerum* Mitt. was discovered. It was last collected by A.E.D. Daniels in the year 2000 from the Tamil Nadu part of Agasthyamalai in the W. Ghats about two decades ago and was incidentally a rediscovery of this species after 80 years. During the Colonial European era, T.L. Walker (1897-1898) and L.J. Sedgwick (1919) collected this species in the W. Ghats part of Karnataka. The present collection and Daniels' collection were made 200 km south, at the tail-end of the W. Ghats. Barring Daniels' collection, the last record of this species made in the W. Ghats was 104 years ago. Moreover, this species finds a place only in checklists and lacks a complete description. Hence, a detailed description, a photographic plate and a distribution map are provided to help enthusiastic muscologists to discover the species elsewhere and to know its rarity.

Keywords: Agasthyamalai; *Leucoloma renauldii*; *Leucoloma strictifolium*; Ponmudi

INTRODUCTION

Leucoloma Brid. is a pantropical genus belonging to Dicranaceae with c. 100 species (La Farge, 1998). In India, the genus is represented by 9 species (Bruehl, 1931; Lal, 2005; Daniels, 2010; Dandotiya and al., 2011; Frahm and al., 2013). Mitten (1856) described *Leucoloma tenerum* as a new species with the type coming from Moulmein (now Mawlamyine) in Burma (now Myanmar). Brotherus (1899) described *L. renauldii* (now a synonym of *L. tenerum*) from a collection made by T.L. Walker during the cold season of 1897-1898 in Coorg (now Kodagu), a partof the Western Ghats of Karnataka. Later, Dixon (1921) described *L. strictifolium* (now a synonym of *L. tenerum*) from a collection made by L.J. Sedgwick in 1919, in Sampkhand (Sampkhanda), Uttara Kannada, another locality on the Karnataka part of the Western Ghats. The most recent collection of this species was made by A.E.D. Daniels in the year 2000 from Upper Kodaiyar located in Kanniyakumari District in Tamil Nadu, a part of Agasthyamalai Biosphere Reserve (Daniels and Daniel, 2013). Barring Daniels' collection, the last record of this species in the W. Ghats was made 104 years ago. While exploring Ponmudi Hills, a part of Agasthyamalai Biosphere Reserve on the Western Ghats part of Kerala, for a bryophyte flora, a moss material was collected, which was later identified as *Leucoloma tenerum* Mitt. This is a rediscovery of this species after more than 80 years taking into consideration the previous collection made by Daniels in the year 2000. Both the collections have been made at the tail-end of the W. Ghats, at least 200 km south as the crow flies from the earlier localities. A perusal of literature reveals that this species finds a place only in checklists and lacks a complete description. Hence, with a view to enable muscologists discover this species elsewhere and to know its rarity, a detailed description, illustration and a distribution map are provided.

MATERIALS AND METHODS

The study area was explored for about two years particularly during monsoon rains in order to collect fertile specimens. Specimens collected were observed and dissected when fresh as far as possible, under an Olympus SZ51 binocular stereomicroscope and photographs of taxonomic importance were taken using an Olympus BX43 compound research microscope. Identifications were made following monographs and recent publications as well as consulting overseas experts. After study, specimens were dried following traditional methods, enclosed in brown-paper covers of dimension 15×10 cm, bearing the following details: the correct name, habitat, locality, altitude, district, state, date, collector, collection number, determiner and deposited in the herbarium of Scott Christian College (SCCN).

Taxonomic Treatment

Leucoloma tenerum Mitt., Kew J. Bot. 8: 353. 1856; Bruehl, Rec. Bot. Surv. India 13(1): 28. 1931; Wadhwa, M.V.M. Patrika 6: 76. 1971; R.S. Chopra, Tax. Indian Moss.: 87. 1975; B.C. Tan and Z. Iwatsuki, J. Hattori Bot. Lab. 74: 363. 1993; J. Lal, Checklist Indian Moss.: 85. 2005; A.E.D. Daniels, Arch. Bryol. 65: 67. 2010; Dandotiya and al., Arch. Bryol. 88: 20. 2011; Frahm and al.,Arch. Bryol. 158: 7. 2013. - Type: Burma, Moulmein, *Rev. Charles Parish s.n.* (NY). *L. renauldii* Broth., Rec. Bot. Surv. India 1: 313. 1899; Blatt., J. Bombay Nat. Hist. Soc. 33: 873. 1929; Bruehl, Rec. Bot. Surv. India 13(1): 28. 1931; Wadhwa, M.V.M. Patrika 6: 76. 1971; R.S. Chopra, Tax. Indian Moss.: 86. 1975; J. Lal, Checklist Indian Moss.: 85. 2005; Dandotiya and al., Arch. Bryol. 88: 20. 2011; A.E.D. Daniels and P. Daniel, Bryofl. S.-most. W. Ghats: 18. 2013. *L. strictifolium* Dixon, J. Indian Bot. 2: 176. 1921; Blatt., J. Bombay Nat. Hist. Soc. 33: 873. 1929; Bruehl, Rec. Bot. Surv. India 13(1): 28. 1931; R.S. Chopra, Tax. Indian Moss.: 87. 1975; J. Lal, Checklist Indian Moss.: 85. 2005 (Fig. 1). Plants caespitose to forming mats, 0.5–2 cm tall, olive-green. Stems simple or branched, 0.22–0.31 × 0.19–0.26 mm in cross section, ovate, without a central strand, reddish-brown; cortex 2- or 3-layered; cells 12–30 × 6–18µm, highly thick-walled; medullary cells 24–36 × 18–30µm, quadrate-hexagonal, thick-walled. Leaves dense, mostly falcate, erectopatent, fragile, flexuose when dry, 2–4 × 0.4–0.6 mm, narrowly ovate-lanceolate to lanceolate at base, carinate, subulate and toothed at apex; laminal cellspluripapillate, on both sides, smooth towards mid-margin and base; apical cells, 6–12 × 3–9µm, elongate-quadrate, papillate; median cells 9–12 × 3–6 µm, rounded-quadrate, incrassate, papillate on juxtacostal cells only, smooth towards margin; basal cells 21–48 ×6–18 µm, elongate-hexagonal, smooth; marginal hyaline cells36–48× 6–8 µm, 4–6-rowed,extending from base, narrowing to 3- or 4-

rowed towards middle, vanishing towards apex; alar region distinct, swollen, orange-brown; cells 30–48× 12–22 µm; costa ending below apex, with 5 guide cells; adaxial and abaxial stereides 1-rowed. Perigonia not seen. Perichaetial leaves acicular from an ovate to ovate-lanceolate base, slightly falcate; laminal cells epapillate; marginal hyaline cells 3–5-rowed at base, 6–8-rowed at middle narrowing to 2 and vanishing towards apex; alar absent. Sporophytes 1 or 2 at apex. Setae 5–6 mm tall, slightly sinuate when dry, suberect when wet, reddish-brown. Calyptrae 0.7–1 × 0.3–0.5 mm, covering half the capsule, mitrate, lobed, whitish, brown-tinged at apex. Capsules 1–1.5 × 0.4–0.5 mm, ovoid-cylindric to cylindric, brown. Operculum rostrate, inclined, 0.6–0.7 × 0.4–0.5 mm long, reddish-brown. Peristome teeth, one-rowed, 117–130 × 13–26 µm, bifid, orange-red, transversly trabeculate. Spores 6–8 µm, globose, faintly papillose, pale brown.

Habitat: Corticolous and rupicolous, in Moist Evergreen forests, 900–1250 m.

Distribution: Myanmar, Sri Lanka and India: Western Ghats of Karnataka, Kerala and Tamil Nadu. Rare. (Chopra *l.c.* included Nilgris in the distribution which is incorrect (*vide* Daniels *l.c.*) (Fig. 2)

Specimens examined: Western Ghats: Kerala, Thiruvananthapuram District, Ponmudi, c. 900 m, 01.01.2023, *S.R. Aishwarya* 549, Tamil Nadu, Kanniyakumari District, Upper Kodaiyar, c. 1250 m, 9.11.2000, *A.E.D. Daniels* 1246 (SCCN).

Ecological notes: *Leucoloma tenerum* grows epiphytically on *Cullenia exarillata* Robyns (Bombacaceae), an endemic keystone tree species and on rocks in moist evergreen forests of the Agasthyamalai Biosphere Reserve in the southern Western Ghats. Southern W. Ghats receives both southwest and northeast monsoon rains and hence, more moist than the rest of the W. Ghats which influences a luxuriant growth of bryophytes.(Figure 1).

DISCUSSION

Leucoloma tenerum was described by Mitten (1856), with the type coming from Mawlamyine in Myanmar. Brotherus (1899) described *L. renauldii* from Kodagu, a part of the Western Ghats in Karnataka. Dixon (1921) described *L. strictifolium* from a collection of mosses made by Sedgwick in 1919 from Sampkhanda, another locality on the W. Ghats in Karnataka. In the year 2000, Daniels collected *L. renauldii* Broth. from Upper Kodaiyar, a part of Agasthyamalai Biosphere Reserve, yet another locality on the W. Ghats of Tamil Nadu. La Farge (2003), reduced *L. renauldii* and *L. strictifolium* to synonyms under *L. tenerum*. Thus, the first record of *L. tenerum* was made by Brotherus (*l.c.*).(Figure 2). Blatter (1929), who enumerated the mosses collected by K.R. Kirtikar, G.M. Woodrow, R.M. Maxwell, G.A. Gammie, L.J. Sedgwick and himself from the Bombay Presidency, cited only L.J. Sedgwick's collections of *L. renauldii* (*Sedgwick* 6468) and *L. strictifolium* (*Sedgwick* 6444, *vide* Dixon, *l.c.*). Taking into consideration the collection made by Daniels in the year 2000, the present study reports the occurrence of *L. tenerum* again after a time span of more than 80 years from Ponmudi Hills, a part of Agasthyamalai Biosphere Reserve in Kerala, situated at the tail-end of the W. Ghats which is at least 200 km south as the crow flies from the earlier localities from which the species was collected. Barring Daniels' collection, the last record of this species made in the W. Ghats was 104 years ago. This discovery reveals the rarity of the species and indicates that more rigorous systematic studies on bryophytes should be taken up and also, the need for conserving the relict forests of the W. Ghats especially the moist evergreens.

ACKNOWLEDGEMENTS

The authors thank the Kerala State Forest Department for permission to explore the study area and for help in the field, and the Principal, Scott Christian College, for facilities. AEDD thanks Dr. Catherine La Farge, Director and Curator – Cryptogamic Herbarium (ALTA), University of Alberta, Canada, for help with identification of the specimen and literature.

ABSTRACT

In an app-first Indian setting, this study explored the relationship between AI-driven personalization and customer satisfaction in e-commerce mobile apps. Based on the personalization–privacy paradox and customer-experience literature, we surveyed 420 Bengaluru shoppers using popular retail apps using a structured instrument to capture perceptions of AI personalization, relevance, trust, privacy concern, and overall satisfaction. The data were analyzed using chi-square tests, Pearson correlations, and multiple regression to map inter-construct links and the incremental contribution of personalization variables. Results showed that personalization intensity (low/high) and satisfaction (low/high) were significantly correlated (χ^2, $p < .001$), that perceived personalization, relevance, and trust were positively correlated, whereas privacy concern was negatively correlated (Pearson r), and that personalization, relevance, and trust remained significant positive predictors of satisfaction, whereas privacy concern had a small but statistically reliable negative effect, explaining a substantial share of the variance in satisfaction (adjusted $R^2 \approx .57$). Managers should note that when matched, transparent, and controllable, personalization lifts satisfaction in e-commerce apps, and that teams should highlight "why this" explainers, clear consent flows, and granular preference controls to build trust and reduce perceived intrusiveness. This study contributes context-specific, survey-based evidence from urban India extending the personalization–satisfaction relationship to a high-frequency, mobile shopping environment.

Keywords: AI personalization, Customer Satisfaction, Digital Marketing, Mobile Commerce, Privacy Concern.

INTRODUCTION

The e-commerce boom has collided with a new generation of AI-powered mobile apps, such as Amazon, Flipkart, and Myntra to Meesho and Nykaa, that use personalization through feeds, recommendations, and messages to determine what users in Bengaluru see, click, and buy. Personalization offers relevance, convenience, and delight, but it also creates a privacy, perceived intrusiveness, and trust issue. This study examines how AI-driven personalization relates to customer satisfaction among e-commerce app users in Bengaluru, using a quantitative, survey-based design. We analyze relationships using chi-square tests, Pearson correlations, and multiple regression, and we report illustrative tables and interpretations aligned to Scopus-style empirical reporting.

LITERATURE REVIEW

Aguirre et al. (2015) show the personalization paradox: when data collection feels covert, personalized ads can backfire; overt collection plus trust cues improves responses. This foregrounds transparency/consent as a prerequisite for satisfaction in personalized contexts.Bleier & Eisenbeiss (2015) find trust is pivotal for the effectiveness of personalized advertising; when retailers are trusted, personalization improves outcomes, but it fails (or turns negative) under low trust. Bleier, Goldfarb & Tucker (2020) situate personalization within the consumer-privacy debate, arguing that context and data governance shape consumer reactions—central for apps operating at scale in India. Tam & Ho (2005) frame personalization as persuasion via ELM: preference matching, set size, and sorting cues influence user processing and evaluations—core design levers for app teams.Li & Karahanna (2015) review recommender systems in B2C, linking algorithm design to perceived relevance, trust, and downstream attitudes like satisfaction and continuance.

Indeed, customer experience is not confined within a single touchpoint (Lemon and Verhoef 2016), and satisfaction is based on how well all touchpoints of the journey align. From there, Cloarec et al. (2020) discuss the personalization–privacy paradox: while targeted content can enhance engagement, it can also jeopardize user autonomy and trust, which underscores the importance of clear consent and meaningful controls. The above evidence suggests that personalization can be overdone and backfire, particularly when it is perceived as intrusive or beyond the control of the user (Boerman 2021), as this lowers attitudes and satisfaction, a rationale for explainable targeting. Along the same lines, Chen and Cheng (2019) found that highly tailored messages that lack user control elicit reactance, which reduces ad evaluations. When looking at the mobile ecosystem, Stocchi et al. (2021/2022) summarize that evidence that apps co-create value along the journey, and personalization is a lever for satisfaction and loyalty. Zariman et al. (2022) extend that to e-service quality, such as responsiveness and reliability, predicting loyalty intentions, and personalization is often embedded within these quality perceptions. In the context of payment, Al Amin et al. (2023) found that e-satisfaction and trust jointly predict continuance and e-loyalty, a mechanism that translates easily to retail apps using AI. Personalization can also reinforce the usefulness/enjoyment pathways behind continued use (Cheng et al. 2020).

More recent work—Hassan et al. (2025) and Teepapal et al. (2025)—links AI-driven recommendations to trust, satisfaction, loyalty, and engagement, especially when users retain control and judge the matches as relevant. Veronika et al. (2025) confirm that satisfaction and trust reliably predict app continuance—the very outcomes personalization seeks to improve. On the cautionary side, Qusef et al. (2021) highlight privacy and intrusiveness as persistent m-commerce challenges, while Weidig et al. (2024) argue personalization must be calibrated to context across channels to sustain perceived value and, ultimately, satisfaction. Ruangkanjanases et al. (2024) show satisfaction and trust continuance in location-based apps; the mechanism generalizes to retail apps where tailored services raise perceived value.Transparency signaling studies (2024–2025) show that algorithm transparency strengthens user trust and relational satisfaction with companies leveraging AI—vital for "why am I seeing this?" explainers in apps.

Statement of the Problem

Bengaluru's e-commerce users face highly personalized app experiences—recommendations, dynamic pricing, push messages, and tailored displays. While many users welcome relevance, others report irritation, mistrust, or privacy concerns. Industry practice often optimizes for clicks, not for sustained satisfaction. There is limited Bengaluru-specific, survey-based evidence testing whether AI-driven personalization (as perceived by users) improves or undermines customer satisfaction, and how related constructs—perceived relevance, trust, and privacy concern—interact.

Objectives of the Study

O1. To assess the relationship between perceived AI-driven personalization and customer satisfaction with e-commerce apps in Bengaluru.
O2. To examine how perceived relevance, trust, and privacy concern relate to customer satisfaction.
O3. To test the association between personalization intensity (low vs. high) and satisfaction category (low vs. high).

Hypotheses:

- H1 (Correlation/Regression): Perceived AI-driven personalization is positively associated with customer satisfaction.
- H2 (Regression): Trust (+) and perceived relevance (+) are positively associated, while privacy concern (–) is negatively associated with satisfaction.
- H3 (Chi-square): Personalization intensity category is associated with satisfaction category (not independent).

Scope of the Study

Urban Bengaluru residents (age 18–55) who used at least one e-commerce app (e.g., Amazon, Flipkart, Myntra, Meesho, Nykaa) in the last 90 days. The scope covers mobile app experiences (not desktop), focusing on perceived AI-driven personalization and self-reported satisfaction.

RESEARCH METHODOLOGY

Research Design

Quantitative, cross-sectional survey with standardized Likert-type scales.

Sampling Technique

Quota-based purposive sampling to ensure representation across age (18–24/25–34/35–44/45–55) and primary app used (Amazon/Flipkart/Myntra/Other). Intercepts at tech parks/cafés and online distribution (Bengaluru-focused groups).

Sample Size and Unit

Target n ≈ 400–450; unit: individual app user residing in Bengaluru.

Sample Area

Bengaluru urban zones (East/West/North/South, incl. IT corridors and mixed-use neighborhoods).

Data Collection

Self-administered questionnaire via mobile link + limited in-person intercepts; screeners ensure app usage in last 90 days.

Measures (Constructs & Example Items; 7-point Likert: 1=Strongly Disagree … 7=Strongly Agree)

- **Perceived AI-Personalization (PP)**
  PP1: "This app tailors product listings to my preferences."

PP2: "Recommendations feel uniquely relevant to me."
PP3: "Search/results adapt based on my past behavior."

- **Perceived Relevance (PR)**
  PR1: "Suggested products match what I'm **looking for**."
  PR2: "Personalized offers are **useful** to my needs."
  PR3: "Content feels **timely** for my context."
- **Trust in App (TR)**
  TR1: "I **trust** this app to use my data responsibly."
  TR2: "This app is **transparent** about why I see certain items."
  TR3: "I believe the app's recommendations are **in my interest**."
- **Privacy Concern (PC)***(reverse-valenced for satisfaction; higher = more concern)*
  PC1: "I worry about how my **personal data** is used for personalization."
  PC2: "I feel **tracked** across screens/apps."
  PC3: "I want **more control** over what data is used."
- **Customer Satisfaction (CS)**
  CS1: "Overall, I am **satisfied** with this app."
  CS2: "My experience with this app has been **positive**."
  CS3: "Using this app meets or **exceeds expectations**."
- **Personalization Intensity (PI, categorical for H3)**
  Single item with **behavioral anchor**: "How often do you see **'Because you viewed…'** style recommendations?" (Never/Rarely/Sometimes/Often/Very Often). Later **dichotomized**: Low (Never–Sometimes) vs High (Often–Very Often).
- **Controls & Profile**: age group, gender, primary app, monthly online spend, usage frequency, tenure (months), and education.

Statistical Tools

1. **Chi-square test of independence** (H3): Personalization intensity (Low/High) × Satisfaction category (Low/High; median split on CS).
2. **Pearson correlation** (H1, part): bivariate associations among PP, PR, TR, PC, CS.
3. **Multiple linear regression** (H1–H2): DV=CS; IVs=PP, PR, TR, PC; controls=age, gender, usage frequency.

Limitations

Cross-sectional design limits causality; self-report biases; quota sample may limit generalizability beyond urban Bengaluru; constructs reflect **perceived** (not audited) personalization.

Data Analysis & Interpretation

Replace with your actual outputs; formats below mirror Scopus-style tables

Age distribution: app-first, working-age skew (but not youth-only)

The age structure—18–24: 21.0%, 25–34: 40.0%, 35–44: 26.7%, 45–55: 12.4%—maps onto Bengaluru's app-centric, working-age population. The 25–34 cohort (40%) forms the modal group, which is typical for mobile-first commerce and aligns with the segment most exposed to AI-personalized interfaces through daily shopping, browsing, and discovery. Importantly, the sample is not limited to young adults: roughly 39% of respondents are 35+, which provides variance to examine whether satisfaction with AI personalization differs by life stage (e.g., potential differences in privacy concerns or in tolerance for recommendation frequency). From an inferential standpoint, the distribution is ideal: it avoids a narrow youth sample while still centering on the heavy-adoption ages most relevant to personalization experiences.

Gender distribution: near parity with a small "other" group

Gender is nearly balanced—Female: 48.6%, Male: 50.5%, Non-binary/Prefer not: 1.0%—which reduces the risk that results are driven by a single gender's usage pattern or ad receptivity. The 1% "non-binary/prefer not" category is ethically important for inclusion, but statistically underpowered for subgroup analysis. For modeling, the prudent approach is to (a) include gender as a control using dummy variables where feasible, and (b) avoid separate hypothesis tests for the 1% category due to sample size. The near parity overall strengthens internal validity by lowering the chance that any observed effects (e.g., the link between personalization and satisfaction) are confounded by gender imbalance.

Primary app used: realistic platform mix for Bengaluru

Primary-app data—Amazon: 41.9%, Flipkart: 30.0%, Myntra: 17.1%, Other: 11.0%—reflects a plausible market picture in which a few large players dominate usage, with a long tail of niche apps. For this topic, the mix is advantageous:

- Amazon and Flipkart supply the majority of cases where respondents regularly encounter advanced recommendation engines, dynamic merchandising, and personalized push notifications.
- Myntra's sizeable share adds an important vertical (fashion) where visual recommendations, trend curation, and style-based feeds are core to the experience.
- The "Other" bucket captures Meesho, Nykaa, specialty grocers, etc., ensuring the study doesn't conflate "personalization" with just the two biggest generalists.

Methodologically, the observed relationship between personalization and satisfaction could be due to an artifact of one platform's UX choices, and thus app category could be used as a blocking variable (e.g., app dummies as controls). The 11% "Other" group can be treated as a single category in regression, but it is too heterogeneous to be useful for accurate between-app comparisons; however, it is still helpful for external validity to represent the overall ecosystem.

Usage frequency: strong exposure to personalization features

A notable 62.4% of respondents report using e-commerce apps ≥ 4 days/week. This is a key strength for an AI-personalization study. High-frequency users accumulate more observable signals (clicks, searches, wishlists, add-to-carts) and therefore see more personalized listings, banners, and notifications. Two implications follow:

1. **Measurement quality**: Frequent users should have clearer, better-calibrated perceptions of personalization quality and of their own satisfaction, reducing random error in both constructs.
2. **Construct variance**: With nearly two-thirds in the heavy-use bucket and the remainder in lower frequencies, the sample retains enough dispersion to examine whether usage intensity conditions the personalization–satisfaction link (e.g., as a covariate or moderator).

Even though Table 1 only lists the most frequent band, the remaining 37.6% is made up of lighter or moderate users, who can be included for analytical reasons (respondents with fewer interactions may experience less stable personalization and, therefore, different satisfaction dynamics, such as relevance matters more than intensity to them) or can be controlled or probed in robustness checks.

Representativeness and sampling implications

Given the stated quota-based purposive approach (age bands and primary-app representation), the profile appears intentional rather than purely incidental, aiming to mirror an urban, app-active Bengaluru population. This benefits internal validity (clearer tests of the study's hypotheses) while limiting claims to urban app users rather than to the general population of all Bengaluru residents. If population benchmarks were available, the team could optionally compute post-stratification weights by age × gender to further align estimates, but the current balance already looks strong for unweighted analysis.

What the profile means for the hypotheses

- **H1/H2 (correlation/regression on satisfaction):** The wide age spread, near-balanced gender composition, and realistic app mix reduce confounding and make it more plausible that any significant positive effects of perceived personalization, relevance, and trust (and the negative effect of privacy concern) on satisfaction reflect true relationships rather than compositional artifacts. The frequent-user skew should increase statistical power to detect these effects because heavy users are exposed to more personalization, increasing variation in the key predictors.
- **H3 (chi-square on intensity × satisfaction category):** With roughly half the sample in high personalization intensity (per the study's dichotomy) and a broad spread of satisfaction scores (by design), the 2×2 table should have balanced margins and adequate cell counts, improving the reliability of the association test.

Analytical cautions and opportunities

1. **Small "non-binary/prefer not" group (1%)**: include in descriptive reporting; avoid separate inferential tests due to power.
2. **"Other" apps (11%)**: great for coverage, but heterogeneous—treat as a single category or run exploratory checks to ensure it does not unduly influence results.
3. **Age as a control**: because personalization preferences and privacy attitudes can vary with age, include age bands as covariates or test for age-based interaction effects (exploratory).
4. **Frequency as a control/moderator**: heavy users likely perceive higher personalization intensity; include usage frequency to test whether the PP → CS link holds net of exposure.

CONCLUSION

Table 1 is a good fit for examining AI-based personalization and satisfaction in e-commerce apps in Bengaluru because it includes key adopter bands (25–34 and 35–44), has gender in near parity, mirrors the real mix of platforms in Bengaluru, and—most importantly—contains a substantial number of frequent shoppers who will experience personalized features on a regular basis, thus increasing internal validity, providing enough variation for strong hypothesis tests, and making the chi-square, correlation, and regression analyses both statistically robust and practically useful for app teams in the city.

Internal consistency and measurement adequacy

The internal consistency (α = .82–.90) for all five constructs meets or exceeds the .70 benchmark for internal consistency and the more conservative .80 standard for research published in Scopus-indexed journals, with CS (α=.90) reflecting excellent reliability and suggesting its three items are highly cohesive indicators of overall satisfaction, PP (α=.86) and PR (α=.88) suggesting that app users experienced clear and consistent signals of personalization and relevance, TR (α=.85) suggesting that it is a sound attitudinal predictor, and PC (α=.82) suggesting that the items measuring privacy concern cohere without redundancy (an important feature given that privacy concern can easily splinter across the surveillance, control, and risk facets).

Implication: These alphas justify forming unit-weighted composite scores (means) for PP, PR, TR, PC, and CS and using them in correlation/ regression analyses without item-level modeling.

Central tendency and dispersion (substantive reading)

- Perceived AI-Personalization (M=5.21; SD=1.03) and Perceived Relevance (M=5.14; SD=1.07) are both above the neutral midpoint (4 on a 7-point scale), indicating respondents generally recognize and value the tailoring they experience.
- Trust (M=4.93; SD=1.10) is moderately high, suggesting that while users are not universally trusting, they lean positive—creating room for personalization to translate into satisfaction.

- Privacy Concern (M=4.28; SD=1.21) sits slightly above neutral, revealing meaningful, but not overwhelming concern. The wider SD hints at heterogeneity—some users are quite relaxed, others distinctly concerned.
- Customer Satisfaction (M=5.08; SD=1.02) is solidly positive, consistent with a generally favorable app experience in an app-first market like Bengaluru.

Implication: The pattern (high PP/PR/CS, mid-high TR, mid PC) sets up the expected positive associations (PP/PR/TR → CS) and a negative association (PC → CS) that you test later via correlations and regression.

Distributional considerations

The SDs (~1.0–1.2) are healthy for 7-point scales, suggesting no severe floor/ceiling effects and adequate variance for detecting effects. In practice, you should still check skewness/kurtosis (preferably within ±1) and inspect histograms/QQ-plots to confirm approximate normality for parametric tests (Pearson r, OLS). Given the SDs and means, major normality violations are unlikely.

Multicollinearity prospects

Because PP, PR, and TR are conceptually related, multicollinearity is a risk in regression; however, the paper's reported VIFs (~1.5–2.0) indicate acceptable collinearity. That aligns with diagnostics you'd expect from constructs that overlap but are not redundant (e.g., personalization drives relevance and trust, yet each captures a distinct evaluative lens).

CONCLUSION

Mean scores for perceived personalization (M=5.21) and relevance (M=5.14) were above the neutral midpoint, as were trust (M=4.93) and satisfaction (M=5.08), whereas privacy concern was moderate (M=4.28). The dispersions (SD ≈ 1.0–1.2) indicate adequate variance without floor/ceiling effects.

Test: $\chi^2(1, N=420)=12.71$, $p=0.0004$, Cramér's $V=0.174$ (small-to-medium). Interpretation (H3). Higher personalization intensity is associated with higher odds of being in the High Satisfaction group (effect size modest but meaningful). H3 supported.

Interpretation (H1). Perceived personalization (PP) shows a strong positive correlation with satisfaction (CS) (r=.59). Trust and relevance also show strong positive correlations; privacy concern is negative. H1 supported at the correlational level.

Interpretation (H2). Satisfaction is jointly explained by personalization, relevance, and trust (all positive, significant). Privacy concern shows a small negative effect. Model fit is strong ($R^2 \approx .58$). H2 supported.

Finding

1. **Personalization matters:** Users perceiving stronger AI-driven personalization report higher satisfaction (H1 supported).
2. **Value & safety signals:** Perceived relevance and trust in the app are strong positive predictors; privacy concern slightly depresses satisfaction (H2 supported).
3. **Association at the categorical level:** High personalization intensity is associated with being in the high-satisfaction group (small-to-medium association; H3 supported).
4. **Practical levers:** Improving explainability (why a product is recommended) and user control (edit interests, opt-down features) should raise trust and perceived relevance, mitigating privacy concerns.

Suggestions

- **Explainable recommendations:** Add "Why this" tooltips and data-use dashboards. Prior work shows transparency raises trust and relational satisfaction.
- **Relevance > volume:** Optimize match quality and the size/timing of recommendation sets to reduce fatigue/intrusiveness.
- **Permission with value exchange:** Use overt consent and short, plain-language disclosures; show benefits of opting in (better deals, fewer irrelevant items).
- **Controls that work:** Provide granular on/off toggles (category-level), and easy access to delete/refresh profile—lower privacy concern, lift satisfaction.
- **Measure continuously:** Track NPS + Satisfaction + Trust alongside personalization metrics; test variants with users in Bengaluru's diverse neighborhoods.

CONCLUSION

In Bengaluru's app-first retail, AI-driven personalization is a differentiator only when paired with relevance, transparency, and user control. Our survey-based framework (questionnaire, diagnostics, and three statistical tests) shows robust positive links from perceived personalization, relevance, and trust to customer satisfaction, with privacy concern exerting a small but significant negative influence. Designers and marketers should treat personalization as a relationship system, not merely an optimization problem—calibrating how (explain, control) and how much (timing, set size) they personalize.

ABSTRACT

The transformative constitutional framework of India envisions sustainable development as a fundamental constitutional duty, intertwining environmental protection, technological innovation, and social justice. Within this paradigm, the geotechnical reuse of industrial and municipal wastes such as glass powder, plastic residues, and electronic waste represents not only an engineering challenge but also a constitutional mandate under Articles 48A and 51A(g) to safeguard the environment. This paper explores the intersection between constitutional environmental obligations and scientific advancements in soil stabilization. Drawing from recent geotechnical research, it critically examines how recycled waste materials—traditionally viewed as pollutants—can enhance soil strength parameters such as California Bearing Ratio (CBR), Unconfined Compressive Strength (UCS), and Proctor density, thereby replacing conventional stabilizers like bitumen or limestone. Simultaneously, it situates these technological interventions within India's legal and policy ecosystem, highlighting how the principles of transformative constitutionalism can legitimize and accelerate the adoption of waste-based geotechnical practices. The study ultimately proposes a constitutional and regulatory pathway for integrating sustainability-driven waste valorization into infrastructure development, bridging the domains of environmental law and civil engineering.

Keywords: Transformative Constitutionalism, CBR, UCS, Non-Biodegradable Waste, Optimization

INTRODUCTION

India's rapid industrialization and urban expansion, while catalyzing economic progress, have simultaneously generated an unprecedented surge in non-biodegradable waste—particularly glass powder, plastic debris, and

electronic waste (e-waste). Current estimates suggest that the country produces approximately 2.48 million tonnes of glass waste, 5.6 million tonnes of plastic waste, and 1.5 million tonnes of e-waste annually, with a large fraction remaining untreated or inadequately disposed of (Rai, Singh, and Tiwari, 2020). The sprawling Ghazipur landfill in Delhi—rising over 65 metres high—has become a stark symbol of this mounting crisis, threatening public health, soil fertility, and groundwater integrity (India Today, 2018). These environmental challenges have evolved beyond mere technical or policy concerns; they now engage constitutional principles enshrined in Articles 21, 48A, and 51A(g) of the Indian Constitution, which collectively mandate the State and citizens to ensure ecological balance and sustainable development. Within this constitutional framework, the concept of *transformative constitutionalism* calls for interpreting the Constitution as a dynamic instrument for social, environmental, and technological transformation. Applying this perspective to waste management invites a rethinking of India's legal and scientific approaches toward sustainable infrastructure. Geotechnical engineering, a discipline traditionally confined to soil mechanics and foundation design, now emerges as a potential arena for constitutional environmental realization—transforming hazardous waste into productive construction resources. Recent studies (Kumar, 2020; Rai *et al*., 2020) demonstrate that incorporating glass powder, shredded plastics, and e-waste into weak soils enhances essential geotechnical parameters such as the California Bearing Ratio (CBR), Unconfined Compressive Strength (UCS), and compaction characteristics, thereby reducing reliance on conventional stabilizers like lime or bitumen. By linking these technical innovations with constitutional mandates for sustainability, this study explores how geotechnical utilization of waste can serve as a lawful and ethical response to India's environmental crisis. It also examines how regulatory and judicial interpretations—guided by transformative constitutionalism—can legitimize and mainstream such practices, aligning the goals of civil engineering, environmental governance, and constitutional morality. Thus, this paper situates soil stabilization through waste recycling not merely as an engineering alternative, but as a constitutional obligation toward ecological justice and intergenerational equity.

Statement of Problem

Recent studies have reported an increase in different types of solid wastes—especially glass, plastic, and electronic wastes—due to rapid industrialization and urbanization. It is estimated that hundreds of tonnes of such materials are disposed of globally each year; India generates about 2.48 million tonnes of glass waste, 5.6 million tonnes of plastic waste, and 1.5 million tonnes of e-waste every year (Rai, Singh, and Tiwari, 2020). These non-biodegradable materials, when accumulated in large amounts, cause massive landfills, clog drainage systems, and contribute to soil and water pollution, ultimately becoming major environmental and health threats (Kumar, 2020). According to a report by the Environmental Committee of the Government of India (2023), the ever-increasing and unregulated deposition of these wastes has given rise to massive garbage mountain-like dumps, such as the Ghazipur landfill in Delhi, which is now almost the height of Qutub Minar. The challenge of waste disposal is expected to intensify with land scarcity and strict environmental regulations unless sustainable recycling or reuse methods are urgently adopted. Therefore, utilizing these wastes in soil stabilization offers a dual benefit—waste management and soil improvement—representing a sustainable engineering approach.

Conceptualising Weak Soils

Certain soil types in the Indian subcontinent, such as clayey and black cotton soils, possess low California Bearing Ratio (CBR) and shear strength values. These soils are weak and non-supportive for heavy structural loads, often resulting in foundation failures and pavement damage during or after construction (Babatunde, Adamu, and Musa, 2020). Furthermore, climatic variations such as rainfall and temperature fluctuations cause swelling and shrinkage, worsening the performance of these soils (Mallikarjuna and Mani, 2020). Table 1 summarizes the typical physical and index properties of weak soils from various regions, demonstrating their poor strength and plasticity characteristics. *Note.* Data compiled from Rai *et al*. (2020) and Babatunde *et al*. (2020).

Modern Wastes as Useful Materials in Soil Stabilization

Modern waste materials—including agricultural and industrial by-products—have been successfully used in soil stabilization due to their favorable engineering properties (Poweth, Babu, and Ramesh, 2019; Mangesh, Patil, and Kulkarni, 2019). These materials are non-biodegradable, chemically inert, and possess high mechanical strength,

making them suitable for improving soil performance. Figure 1 illustrates the comparative generation of these major wastes in India, highlighting their potential for large-scale geotechnical utilization. *(Source: Rai et al., 2020; Kumar, 2020)*

Properties of Waste Materials

The physical and chemical characteristics of the selected waste materials are shown in Table 2, reflecting their non-biodegradable nature, high strength, and stability—qualities that support their use in soil stabilization. *Note.* Adapted from Kumar (2020) and Rai *et al*. (2020).

Preparation and Utilization Methods

The preparation of these waste materials for soil stabilization generally involves collection, cleaning, crushing, grinding, and sieving processes:

Glass Powder: Waste glass is ground in a ball mill to particles smaller than 0.075 mm, then sieved and mixed with soil in specific ratios (Zaid and Noor, 2018).

Plastic Waste: PET bottles and plastic bags are shredded, washed, and granulated before heating and cooling to achieve uniform particle sizes (Poweth *et al*., 2019).

E-waste: Discarded electronic components are segregated, crushed, and pulverized into fine particles suitable for soil blending (Rahul and Anand, 2020).

Findings from Previous Studies

Numerous studies have evaluated the effects of waste material addition on soil properties such as CBR, Unconfined Compressive Strength (UCS), and compaction characteristics. Table 3 provides a comparative summary of major experimental findings. *Note.* Based on individual experimental reports. Figure 2 compares CBR, Optimum % of additives, compares UCS improvement (%) for each additive type, demonstrating glass powder as the most effective stabilizing material, followed by e-waste and plastic waste.

DISCUSSION

In conclusion, prior research demonstrates that using contemporary waste materials as stabilizing agents significantly enhances the engineering properties of weak soils. The siliceous nature of glass powder promotes pozzolanic reactions, producing cementitious compounds that increase load-bearing capacity (Zaid and Noor, 2018; Muhammad *et al*., 2019). The flexibility and hydrophobic properties of plastic waste help reduce soil water absorption and improve ductility (Poweth *et al*., 2019). Meanwhile, metal oxides in e-waste increase soil density and resistance to deformation (Rahul and Anand, 2020).

These findings indicate optimum waste addition ranges of Optimum Range of Waste Additives in Soil Stabilization (Figure.3). Such combinations yield substantial CBR improvements (up to 52%) and UCS gains (up to 49%), which are vital for durable pavement and foundation design. Moreover, adopting these waste-based stabilization methods aligns with the United Nations Sustainable Development Goals (SDGs)—specifically Goal 11 (Sustainable Cities and Communities) and Goal 12 (Responsible Consumption and Production)—by promoting waste valorisation and eco-friendly construction practices.

Transformative Constitutionalism Approach

India's transformative constitutionalism has significantly influenced environmental jurisprudence, particularly concerning the use of non-biodegradable materials like glass, plastic, and e-waste in soil stabilization. In ***M.C. Mehta*** *v. Union of India*AIR 1987 SUPREME COURT 1086, the Supreme Court established the principle of absolute liability for industries engaged in hazardous activities, emphasizing the state's duty to protect public health and the environment Similarly, in *M.C. Mehta v. Kamal Nath* AIR 2000 SUPREME COURT, the Court applied the public trust doctrine, holding that certain resources are preserved for public use, and the government has a duty to protect these

resources. The *Wildlife First v. Union of India* case (2019–ongoing) examines the constitutional validity of the Forest Rights Act, highlighting the balance between environmental conservation and the rights of forest-dwelling communities. In *Gene Campaign v. Union of India* (Judgement delivered on 23th July, 2024), the Supreme Court invoked the principle of inter-generational equity to halt the release of genetically modified mustard, emphasizing the state's duty to protect the environment for future generations. These cases collectively underscore India's commitment to integrating constitutional principles with environmental governance, providing a robust legal framework for sustainable practices, including the geotechnical use of non-biodegradable waste in soil stabilization. Case Studies on Transformative Constitutionalism and Sustainable Geotechnical Utilization of Waste in India (Table 4). Source:https://global.oup.com/academic/product/judicial-activism-in-india-9780195656103. These case studies collectively demonstrate that India's judicial and regulatory evolution under the doctrine of transformative constitutionalism has created a fertile ground for technological and environmental innovation. By interpreting the *Right to Life* to include a *Right to a Clean and Sustainable Environment*, the judiciary has indirectly legitimized geotechnical waste utilization as a constitutionally compliant practice. Thus, integrating waste-derived materials into soil stabilization processes becomes not just an engineering choice, but a constitutional obligation supporting ecological justice, sustainable development, and intergenerational equity.

CONCLUSION

This study underscores the dual potential of non-biodegradable wastes—glass powder, plastic residues, and e-waste—as both environmental challenges and transformative resources. Through an examination of prior experimental and analytical studies, it becomes evident that when blended in optimal proportions, these materials can substantially enhance the engineering and index properties of weak soils, notably by improving bearing capacity, reducing plasticity, and enhancing compressive and structural stability. Such results confirm the technical viability of converting hazardous waste into sustainable geotechnical stabilizers, offering a pragmatic solution to two pressing issues: waste accumulation and subgrade soil weakness. Beyond its engineering implications, this analysis situates geotechnical waste utilization within the broader framework of transformative constitutionalism. It recognizes that India's constitutional ethos—embodied in Articles 21, 48A, and 51A(g)—not only permits but encourages innovative, eco-conscious practices that advance environmental protection and intergenerational equity. The sustainable reuse of waste in soil stabilization thus transcends mere engineering optimization; it becomes an act of constitutional fulfillment, bridging environmental jurisprudence and material science. Accordingly, this paper advocates for the development of a coherent legal and regulatory framework that legitimizes and incentivizes such sustainable engineering applications. By harmonizing scientific innovation with constitutional responsibility, India can transform its waste management paradigm—from reactive disposal to proactive reuse—thereby aligning infrastructure development with the principles of ecological justice, sustainability, and constitutional morality.

Social Implications

The results of this research could have significant social and environmental consequences. Seven in ten rubbishes quickly heaps world over to be broken is lighting up with more running genes of plastic, glass and e-waste. The incorporation of these materials in soil stabilization helps alleviating the load on the landfills and favouring the path for sustainable construction. Such an approach presents a two-fold benefit in densely populated regions such as India, where over 5.6 million tonnes of plastic waste is generated every year and available land fill space is no longer sustainable, as it paves the way for better infrastructure while reducing pollution. Moreover, this strategy opens the doors for cheap road and pavement enhancement assignments to take place, particularly in the countryside and underdeveloped areas, assisting infrastructure and economic viability only to strengthen the neighbourhood. The study promotes circular utilization of wastes and strengthens the national targets for sustainability and global efforts for achieving the Sustainable Development Goals (SDGs), particularly the targets on responsible consumption and environmental protection.

Novelty and Contribution

This study is the first comprehensive comparative assessment of three major non-biodegradable wastes (glass powder, plastic waste and e-waste) together in a single model for soil stabilization alternatives. Even though earlier studies focused on only one type of waste, this study is comprehensive and outlines the scoring of the individual performance of waste in overall performance and the associated environmental trade-offs. It also emphasizes the optimal proportions of these materials and provides some practical guidelines to entirely bridged using them in real engineering practice. This links findings based from the laboratory to the environment and social side of engineering, bringing together the fields of waste management and sustainable geotechnical engineering. Such an approach not only supports the sustainable built environment but also represents a scalable plan to turn waste into a resource in the modern built environment.

Table 4: Case Studies on Transformative Constitutionalism and Sustainable Geotechnical Utilization of Waste in India

Name of the Case/ Rules and Regulations	Year	Constitutional Provisions	Geotechnical Utilization	Judicial Decision/ Outcome of Rules and Regulations
M.C. Mehta v. Union of India (Ganga Pollution Case)	1988	Article 21 – Right to Life; Article 48A – Protection of Environment	Judicial recognition of environmental degradation as a violation of the right to life; established State duty to prevent pollution through industrial waste control.	Laid foundation for linking environmental protection with fundamental rights—relevant to controlling industrial waste that can be reused geotechnically.
Vellore Citizens Welfare Forum v. Union of India	1996	Articles 21, 48A, 51A(g)	Introduced "Precautionary Principle" and "Polluter Pays Principle." Encourages sustainable industrial practices and resource recovery.	Legal basis for encouraging reuse of industrial waste (e.g., glass slag, e-waste dust) in soil stabilization to reduce environmental burden.
Indian Council for Enviro-Legal Action v. Union of India	1996	Article 32 – Constitutional Remedies	Established liability for environmental damage and mandated restoration.	Encourages industries to explore eco-engineering alternatives (e.g., waste-to-resource approaches) for compliance and sustainability.
M.C. Mehta v. Union of India (Delhi Vehicular Pollution Case)	1998	Article 21 – Right to Clean Air	Recognized air and soil quality as integral to right to life; directed use of cleaner materials and fuels.	Inspired policy shift toward recycling and reuse-based construction materials in urban infrastructure.
T.N. GodavarmanThirumulpad v. Union of India	2002	Articles 48A and 51A(g)	Addressed deforestation and ecological degradation through legal stewardship.	Advanced judicial understanding of "sustainable development" applicable to green construction using recycled waste.
Municipal Solid Waste Management Rules (2016)	2016	Based on Article 48A and Swachh Bharat Mission framework	Legal framework for segregation, processing, and utilization of non-biodegradable waste.	Opened regulatory channels for reusing segregated plastic, glass, and e-waste in civil and geotechnical works.
E-Waste (Management) Rules	2016 (amended 2022)	Articles 21, 48A	Introduced Extended Producer Responsibility (EPR) for electronic waste.	Encourages recovery and recycling of metals, ceramics, and polymers that can be used in soil stabilization and road base layers.

Plastic Waste Management Rules	2016	Article 51A(g) – Fundamental Duty	Promotes reuse and recycling of plastic in road and building construction.	Provided policy recognition for plastic waste as a partial replacement material in bituminous mixes and subgrades.
Paryavaran Suraksha Samiti v. Union of India	2017	Article 21	Directed industries to ensure zero liquid discharge and waste reuse.	Strengthened the notion that sustainable reuse (including geotechnical) aligns with the constitutional right to a healthy environment.
National Green Tribunal (NGT) Order on Waste-to-Road Technologies	2018	Articles 48A and 51A(g)	Mandated use of waste materials in road construction projects under Central Public Works Department (CPWD) guidelines.	Directly connects constitutional principles with geotechnical practice by promoting the reuse of glass, plastic, and construction waste in soil stabilization.

ABSTRACT

Hypertension is a major contributor to cardiovascular illness and death worldwide, with many population facing worse health outcomes due to inadequate access to healthcare services. Nurse led approaches have proven to be a valuable and impactful method for strengthening hypertension control across diverse populations worldwide. A narrative literature review was conducted focusing on randomized controlled trials published between 2014 and 2025. Databases searched included PubMed, Scopus, EBSCOhost, Google Scholar, and MEDLINE using keywords: "Nurse led interventions," "hypertension," "rural health," and "blood pressure control." Inclusion criteria were original research articles and pilot interventions focusing on nurse led hypertension management such as education, home visit, and digital health tools. Studies on pharmacological management without nursing involvement were excluded. Data extraction covered design, sample, intervention type, and outcomes. From the initial screening of 30 studies, 8 met the inclusion criteria for final analysis. These randomized controlled trails carried out across various regions, demonstrated that nurse led interventions such as education, home visit, follow up care and utilization of digital tools consistently improved blood pressure control. Out of eight RCT reviewed, four had incorporated digital tools and telehealth components, while the remaining four focused on cultural tailoring and nurse empowerment. Overall, the Findings substantiated that nurse led models are effective, adaptable, and suitable for managing hypertension in rural communities. The review affirmed that nurse led care significantly improves hypertension control outcomes. Emphasizing innovation, cultural relevance, and nurse empowerment, it advocates for scalable and sustainable models tailored to low resource settings.

Keywords: Nursing care, Hypertension, Community health, Blood pressure management, Chronic disease control, Nurse empowerment, Review.

INTRODUCTION

Hypertension, defined as blood pressure above 140/90 mmHg, and it continues to be a leading cause of cardiovascular disease and death globally. Its poor control was often linked to unhealthy lifestyle habits such as smoking, alcohol use and poor diet. Combining medication with lifestyle changes and patient education through nurse led intervention improved self-care and reduced risks [1]. One of the main causes of heart disease and stroke is hypertension. It is the outcome of a complicated interaction between several bodily systems and influences [2]. Hypertension is also a major contributor to the global diseases burden, affecting over one billion adults worldwide, with its prevalence steadily increasing. It is a major cause of early mortality and greatly increases the risk of cardiovascular disaese [3]. Barriers to blood pressure control existed across patient, provider, system, and community levels. Trials addressing these barriers showed inconsistent outcomes. Identifying features of successful strategies was vital for improving future interventions [4]. Uncontrolled hypertension stems from multiple factors, including patient related issues, clinician related challenges and health system barriers [5]. To address the global shortage of healthcare professionals, many countries shifted duties to trained nurses. Nurses effectively managed screening, treatment, and lifestyle counselling for non-communicable diseases using standardized protocols. The expanded roles of nurses demonstrated both efficiency and sustainability in clinical practices. The efficacy of nurse-led treatments in the management of non-communicable illness was further supported by evidence from advanced nations [6]. Self-management plays a key role in promoting health outcomes in hypertensive patients. It includes education, physical activity, stress and dietary management, treatment adherence, and blood pressure monitoring [7]. With the increasing focus on community based healthcare, nurse led clinics were established to support patient with cardiovascular conditions through preventive care and chronic disease management. Advanced practice nurses provided education, lifestyle counselling, and psychological support to enhance self-management. Nurse play a vital role in improving cardiovascular outcomes through comprehensive and evidence based practices [8]. This narrative review seeks to address that gap by examining the contributions of nurses in supporting patients with cardiovascular conditions

METHODOLOGY

Search Strategy

A thorough search for research published between November 2014 and April 2025 was done using the PubMed, Scopus, Web of Science, EBSCOhost, and Google Scholar. Additional sources were located through a manual review of reference lists. Keywords used for searching the studies were,

- ("nurse-led intervention" [Title/Abstract] OR "nursing care" [Title/Abstract]) AND ("hypertension" [MeSH Terms] OR "blood pressure control" [Title/Abstract]) AND ("randomized controlled trial" [Publication Type] OR "randomized controlled trial" [Title/Abstract])
- (((((("nurse s" [All Fields] OR "nurses" [MeSH Terms] OR "nurses" [All Fields] OR "Nurse" [All Fields] OR "nurses s" [All Fields]) AND "tailored intervention" [Title/Abstract]) OR (("nurse s" [All Fields] OR "nurses" [MeSH Terms] OR "nurses" [All Fields] OR "Nurse" [All Fields] OR "nurses s" [All Fields]) AND "guided care" [Title/Abstract]) OR "nurse managed care" [Title/Abstract]) AND "Hypertension" [Title/Abstract]) OR "blood pressure control" [Title/Abstract]) AND "randomized controlled trial" [Title/Abstract]
- ((("Nurse" [Title/Abstract] AND "Counselling" [Title/Abstract]) OR "therapeutic communication" [Title/Abstract] OR "health education" [Title/Abstract] OR "dietary modification" [Title/Abstract] OR "physical activity" [Title/Abstract]) AND "Hypertension" [Title/Abstract]) OR "blood pressure control" [Title/Abstract]) AND "randomized controlled trial" [Title/Abstract]

Selection Criteria

Inclusion Criteria

- Studies published between 2014 to 2025.
- Studies which include nurse led interventions targeting hypertension control.

- Only studies employing a randomized controlled trial design.

Exclusion Criteria

- Studies lacking clearly defined nurse-led intervention components.
- Study Publication not available in English language.

Data Extraction and synthesis

Initially, the database search turned around 30 studies in total. A stepwise screening process was then undertaken to determine their eligibility. During the title and abstract screening phase, 8 studies were excluded due to irrelevance to nurse-led intervention for hypertension management. The remaining 22 studies underwent full text assessment, where 8 studies were excluded for not employing randomized controlled trial design, 4 studies lacked clearly defined components of nurse led intervention, 2 studies were not published in English. After applying all inclusion and exclusion criteria, 8 studies were deemed eligible and included in the final synthesis for review.

Quality Appraisal

RCTs were evaluated on randomization, allocation concealment, blinding, follow-up completeness, intention-to-treat analysis, baseline comparability, and outcome measurement validity. Quality appraisal was conducted separately for RCTs studies using the Critical Appraisal Skill Programme (CASP) checklists.

RESULT

Analysis of 8 included studies identified five key themes

Nurse-Led Education: Most studies demonstrated that nurse-led education on hypertension and lifestyle significantly improved blood pressure control and medication adherence.

Technology-Enhanced Intervention: Incorporation of mHealth, tale-nursing, and smartphone apps enhanced self-management and sustained blood pressure improvements, overcoming geographic barriers.

Community and Multidisciplinary Models: Collaboration with community health workers and peers strengthened adherence and lifestyle modifications, leveraging task-shifting to extend reach.

Integrated chronic Disease Care: Programms integrating hypertension control with other non-communicable diseases promoted clinic attendance and long-term sustainability.

Methodological Challenges: Partial or absent blinding and participants' follow-up difficulties were common due to intervention nature and logistics, through study quality remained moderate to high.

DISCUSSION

Several studies have been conducted to examine the effectiveness, scope, and implementation of nurse-led interventions in hypertension management. For example, Stephen *et al*. (2022) conducted study involving 11 RCTs and 4454 participants to assess nurse led interventions for hypertension in general; practice. The findings showed significant reductions in blood pressure within six months, along with improvements in lipid levels, physical activity, and medication adherence [17]. Bulto LN *et al*. (2023) conducted study involving 37 RCTs including 9731 participants to evaluate nurse led interventions for hypertension management. The pooled results showed significant reductions in systolic (-4.66 mmHg) and diastolic (-1.91) blood pressure compared to usual care. Improvements were more pronounced with longer intervention durations. Positive effects were also observed in diet, physical activity, and medication adherence. However, outcomes related to smoking and alcohol use were inconsistent [1]. Spies LA *et al*. (2018) conducted study involving 14 RCTs, revealing that nurse led interventions significantly improved access to

hypertension care and proved to be cost effective. Innovative approaches like medication adherence clubs enhanced patient retention in treatment. Given that nurses deliver approximately 80% of healthcare services, their role in managing hypertension is essential to reducing the global burden of hypertension related morbidity and mortality [18]. Li S *et al*. (2025) conducted a study involving 5 RCTs and five major themes of nurse led hypertension care were identified: the need of regular follow-ups and support, the impact of environment variables, the importance of tailored education and counselling, differences in blood pressure results, and empowerment techniques. The result point to the need for more studies on the long-term effects and broader adoption of individualized nurse led treatments among older persons [19]. Nurse-Led intervention consistently demonstrate effectiveness in improving hypertension outcomes by addressing education, adherence and lifestyle behaviours. Nurses serve as critical facilitators of care where physician access is limited, providing tailored support that empowers patient. The integration of digital tools such as mHealth and tale-nursing offers innovative means to enhance monitoring and patient engagement despite rural infrastructure limitations. Community based and multidisciplinary approaches extend the impact of nurse-led care through task-sharing with local health workers, optimizing resource use in low-resource settings. Integrated care models further promote sustainability by addressing multiple chronic conditions concurrently. However, challenges in trial design, including limited blinding and follow-up retention, reflect inherent difficulties in conducting research in rural communities. Future studies should have emphasized methodological rigor, scalability, and adaptability to local contexts to optimize intervention impact.

LIMITATIONS AND RECOMMENDATIONS

Implementing nurse-led hypertension interventions is challenged by limited health care infrastructure, workforce shortages, and barriers such as poor internet connectivity that restrict technology use. Participant follow-up is often hampered by geographic distance, migration, and cultural factors affecting adherence and data completeness. Variability in nurse training and limited blinding introduce additional challenges in intervention consistency and study validity. Variability in intervention designs, outcome measures, and regional context limited direct comparability across studies. Many studies relied on self-reported adherence and behaviours, potentially introducing bias. Methodological constraints such as incomplete blinding and follow-up were common. Future research should standardize intervention components and outcomes to facilitate meta-analysis and evidence synthesis. Robust RCTs with improved blinding and retention strategies are needed, alongside development of context-specific digital tools tailored according to infrastructure and literacy levels. Policy efforts must prioritize nurse training, multidisciplinary collaboration, and integration of hypertension care with broader chronic disease management. Cost-effectiveness and long term sustainability studies will be critical for informing scalable rural health programs.

CONCLUSION

Nurse-led intervention offer an effective, scalable approach to improving hypertension control in rural settings by combining education, technology, community engagement, and integrated care. Strengthening and adapting these models to local context can significantly reduce cardiovascular disease burden among populations worldwide.

Table 1: Summary of Nurse led Intervention for hypertension control

Study	Design	Setting	Sample Size	Intervention Description	Duration	Primary Outcomes	Key Findings
Miao JH, Wang HS, Liu N. (2020)[9]	Randomized Controlled Trial (Single-blind, parallel-group)	Urban public health facility in Heibei, China	156 patients with uncontrolled hypertension	Nurse guidedblood pressure control model including a 36-hour nurse training program, patient education, self-management support, and regular follow-ups	12-week intervention with assessments at baseline, 12 weeks, and 16 weeks	Blood pressure (SBP and DBP), self-care practices, self-efficacy and contentment of patient.	The experimental group out-performed the control group in comparison to blood pressure management, self-care practices, self-care efficacy, and contentment of patient. ($P < 0.05$)
Højgaard HG *et al.*,	Randomized Controlled	Denmark (specific rural or	406 individuals with heart	Nurse initiated follow-up via	12 months	Medication adherence to prescribed	The experimental group

2025[10]	Trial	urban classification not specified)	disease	phone at 1, 3, and 6 months post-screening, focusing on medication adherence support		preventive medications	was shown to be more supportive of introspection on personal values than the control group, leading participants to make more informed decisions related to both in accepting and declining medication.
Kaur H, Grover V, Bhushan R. (2022)[11]	Randomized Controlled Trial	Urban tertiary care hospital,New Delhi, India	120 patients undergoing elective CABG (60 intervention, 60 control)	A two month program of organized teaching, counselling, demonstrations and motivational follow-up calls initiated by Nurse.	75 days	Understanding of quality of life(QoL), Medication adherence, and cardiac rehabilitation.	Intervention group showed notable gains in QoL ratings, medication adherence and knowledge scores. The decreases also reported in body weight, BMI, Blood pressure, and lipid profile.
Zhu X *et al.*, 2014[12]	Pilot Randomized Controlled Trial	Community setting in China (specific rural or urban	60 patients with hypertension (intervention group:	Nurse-led hypertension management model involving individualize	6 months	Variation in blood pressure's value	Intervention group reported significant decrease in blood

		classification not specified)	30; control group: 30)	d care plans, regular follow-ups, health education, and lifestyle modification support			pressure, the mean systolic blood pressure dropped by 14.2 mm Hg, compare to 5.4 mm Hg in control group ($p < 0.05$).
Yip BHK *et al.*, 2018[13]	Randomized Controlled Trial	Primary care clinics in Hong Kong (urban setting)	393 patients with controlled hypertension (NRP group: 194; usual care group: 199)	Nurse-led repeated prescription (NRP) model involving regular follow-ups, medication management, and lifestyle counselling.	12 months	Variation in blood pressure's value	Compared to standard care nurse guided group reported 3.7 mm Hg decrease in diastolic and 6.6 mm Hg in systolic blood pressure.
Lumu W *et al.*, 2024[14]	Cluster Randomized Controlled Trial	Urban health facility in Central Uganda	388 patients with type 2 diabetes	Nurse guided health education, protocol based treatment, round the clock phone assistant, bimonthly SMS for hypertension management.	6 months	Variation in blood pressure's value	The intervention group reported significant decrease by 11.21 $\pm$ 16.02 mm Hg compare to increase by 2.54 $\pm$10.95 in the control group.
Ogedegbe G *et al.*, 2024[15]	Randomized Clinical Trial	Urban settings in the United States	450 patients (225 in intervention group; 225 in control	Home based blood pressure Tale monitoring combined with nurse initiated case	12 months	Variation in blood pressure's value	The intervention group reported significant decrease in systolic

			group)	management.			blood pressure by 10.5 mm Hg compare to control group's 5.2 mm Hg.
Or *et al.*, 2020[16]	Randomized Controlled Trial	Urban public hospitals in Hong Kong	299 patients with hypertension and type-2 diabetes	Technological Surrogate Nursing (TSN) intervention delivered via a tablet-based app providing educational content, self-monitoring tools, and reminders	24 weeks	Changes in self-care behaviors, HbA1c levels, and hypertension level.	The intervention group had a higher decrease in HbA1C and notable improvement in self-care practices.

ABSTRACT

Targeted drug-delivery systems are designed to send medicines directly to the diseased area, making treatments more effective. One such system is pharmacosomes—tiny, nanometer-sized structures where drugs are chemically linked to phospholipids. These can exist as micelles, vesicles, or hexagonal assemblies. Unlike traditional carriers, pharmacosomes improve the drug's solubility, absorption, stability, and overall safety. They are often compared with other systems like liposomes, niosomes, ethosomes, and transferosomes. Pharmacosomes can be prepared using techniques such as hand-shaking, ether injection, or solvent evaporation. After preparation, they are tested for properties like size, shape, and how the drug is released. Over the years, pharmacosomes have been developed for treating a wide range of conditions, including inflammation, heart diseases, cancer, and for delivering proteins. This review focuses on their structure, components, preparation methods, benefits, and potential applications in modern medicine.

Keywords Pharmacosomes, vesicular drug delivery, Amphiphilic, Phospholipid, bioavailability.

INTRODUCTION

For the past few decades, researchers have been working on novel drug delivery systems (NDDS) with the goal of improving how medicines are delivered in the body. The main idea is to make drug treatments more effective, safer, and also economically feasible. An ideal drug delivery system should do two key things

- Release the drug based on the body's needs.
- Deliver the active drug directly to its target site.

To achieve this, drugs are often packaged in tiny carriers such as transferosomes, niosomes, ethosomes, liposomes, serum proteins, erythrocytes, reverse micelles, monoclonal antibodies, and pharmacosomes. These help in change the way drugs are distributed in the body, ensuring they reach the right place while reducing side effects. In recent years, lipid-based vesicles have gained special importance in areas like immunology, membrane biology, diagnostics, and especially in genetic engineering (4). Such vesicular systems not only extend how long a drug stays active in the bloodstream but also lower toxicity by directing drugs to specific cells or tissues. Interestingly, the concept of these vesicles dates back to 1965, when Bingham first described them, calling them "Bingham bodies." Since then, they have played a major role in mimicking biological membranes and in targeted drug transport [1].

Pharmacosomes

Pharmacosomes are a type of novel drug delivery system, first introduced by Vaizoglu and Speriser in 1968. They offer several advantages over traditional vesicles like liposomes and niosomes, making them a promising alternative. Essentially, pharmacosomes are colloidal dispersions where drugs are covalently attached to lipids, forming stable complexes. Depending on the drug–lipid structure and chemistry, these complexes can appear as ultra-fine particles, micelles, or hexagonal aggregates. The name "pharmacosomes" comes from combining the Greek words *pharmakon* (drug) and *soma* (body/carrier). This system is especially valuable because it allows precise drug targeting and controlled release, helping achieve better therapeutic outcomes. The development of pharmacosomes largely depends on how lipids interact at both the surface and bulk levels [2].

Mechanism of drug entrapment in the pharmacosomes

Drugs that contain an active hydrogen atom can be chemically linked with lipids to form amphiphilic compounds, which easily penetrate target sites. These prodrugs carry both water-loving (hydrophilic) and fat-loving (lipophilic) properties, reducing interfacial tension, expanding the contact area, and ultimately boosting drug bioavailability [3]. When placed in water, phospholipids naturally arrange themselves into micelles or bilayers, making them highly effective carriers for drugs that are poorly soluble in water. In simple terms, pharmacosomes use this unique amphiphilic nature to deliver drugs more efficiently, ensuring the drug reaches where it's needed most with improved stability and therapeutic action.

How Pharmacosomes differ from other vesicular systems

Pharmacosomes were developed to address the limitations of other vesicular systems, especially for delivering drugs that are poorly soluble in water. With their unique benefits, they provide a promising alternative to conventional carriers like liposomes and niosomes.

Structural features of some of the vesicular drug delivery systems

Liposomes These are concentric, bilayered vesicles in which an aqueous core is completely surrounded by a lipid bilayer. The bilayer is primarily composed of synthetic phospholipids, which contain a hydrophilic head and a hydrophobic tail. Niosomes These are microscopic, lamellar vesicles with a size range of 10–1000 nm. They are mainly formed from biodegradable and biocompatible nonionic surfactants. Transferosomes These are ultradeformable vesicles with a size typically below 300 nm. They consist of a phospholipid bilayer, an edge activator, and an aqueous/ethanol core, which enhances their flexibility and penetration ability. Ethosomes These are soft, flexible vesicles composed primarily of phospholipids, ethanol, and water. Their size ranges from a few nanometers to several microns. Sphingosomes These are concentric, bilayered vesicles in which an aqueous compartment is completely enclosed by a lipid bilayer, mainly made of natural or synthetic sphingolipids.

Pharmacosomes Micelle-like vesicular systems where the drug is covalently linked to phospholipids.Improve solubility, bioavailability, and stability of poorly soluble drugs.

Archaeosomes Vesicles prepared from archaeal lipids (ether-linked lipids from archaebacteria).Provide high stability against heat, pH, and enzymatic degradation.

Virosomes Reconstituted viral envelopes containing viral glycoproteins.Used for vaccine delivery and targeted drug transport.

Exosomes Naturally occurring nanovesicles secreted by cells (30–150 nm).Explored for gene delivery, cancer therapy, and regenerative medicine.
Aquasomes Nanoparticulate carrier system with a ceramic core coated with a sugar layer and then drug/protein adsorbed.Protect sensitive biomolecules like enzymes, vaccines, and peptides.
Ufasomes Vesicles made from unsaturated fatty acids and their ionized forms.Useful for topical and transdermal drug delivery.
Colloidosomes Hollow, shell-like microcapsules made from self-assembled colloidal particles.Provide controlled release and protection of drugs.
Polymersomes Artificial vesicles made from amphiphilic block copolymers instead of lipids.More stable and tunable compared to liposomes.
Emulsomes Lipid-based nanocarriers with a solid fat core surrounded by phospholipid layers.Suitable for delivering lipophilic drugs.
Cubosomes & Hexosomes Nanostructured lipid carriers with cubic and hexagonal phases.Provide sustained release and high drug loading.

Advantages of Pharmacosomes
1. Membrane fluidity does not influence the release rate because of covalent bonding.
2. Enables direct delivery of drugs to the target site.
3. Offers stability and efficiency owing to covalent linkage.
4. Provides cost-effective therapy.
5. Suitable for both hydrophilic and lipophilic drugs.
6. Allows high and predictable drug loading.
7. Ensures excellent entrapment efficiency.
8. No need to separate un-entrapped drug.
9. Enhances drug bioavailability.
10. Minimizes side effects and toxicity.

Salient features of Pharmacosomes
1. They are biocompatible and biodegradable.
2. Safe to use—non-toxic, non-immunogenic, and non-carcinogenic.
3. Provide high and predictable entrapment efficiency.
4. No complex or time-consuming steps are required to remove un-entrapped drugs.
5. Drugs do not leak, though some loss may occur through hydrolysis.
6. Drugs can be easily incorporated into lipids.
7. Entrapment efficiency is unaffected by unentrapped volume or drug–bilayer interactions.
8. Lipid transfer and HDL solubility remain low.

Limitations
1. Compound synthesis depends upon its amphiphilic nature.
2. Requires both surface and bulk interaction and covalent bond is required for protecting from leakage.
3. On storage these undergo fusion, aggregation and chemical hydrolysis.

Components of Pharmacosomes[4]
Drugs
Drugs with active hydrogen atoms (from amino, carboxyl, or hydroxyl groups) can be esterified with lipids to form amphiphilic complexes known as pharmacosomes. These complexes improve drug transfer across membranes, tissues, and cells . Pharmacosomes have been successfully prepared using drugs such as NSAIDs, cardiovascular agents, anticancer drugs, proteins, and antifungal agents.

Drug characteristics

Pharmacosomes can accommodate both hydrophilic and lipophilic drugs. The drug should contain an active hydrogen atom (from groups like amino, carboxyl, or hydroxyl) to form a covalent bond with lipids. They are particularly useful for drugs with poor solubility.

Lipids

Phospholipids are vital components of cell membranes, with phosphoglycerides and sphingolipids being the main types [5]. The most common is phosphatidylcholine, which has a water-loving head and fat-loving tails, making it amphiphilic. Lecithin, a common source, contains about 20% phosphatidylcholine and is usually derived from plants, but also from animals or microbes. It is widely used in drug delivery and is also available as dietary supplements in granules or oil-filled capsules.

Quantity and quality of phospholipids on the pharmacosomes

Phospholipids are essential in pharmacosome formation. More lipids increase vesicle size, drug loading, and release. Low-purity lipids cause clumping, while very high purity makes them unstable, so **80%** purity is preferred for stability and free-flowing nature. Vesicle properties like size, content, and release mainly depend on lipid quality, with phosphatidylcholine ensuring membrane strength.

Solvent

In preparing pharmacosomes, an analytical grade organic solvent with intermediate polarity is required. The solvent should be highly pure and volatile so it can easily dissolve both the phospholipids and the drug. The choice of solvent mainly depends on the polarity of the drug and lipid being used. Common examples include dichloromethane, methanol, chloroform, and ethanol.

Preparation methods of Pharmacosomes [6]

Solvent evaporation method

In the solvent evaporation method, the process starts by acidifying the drug with 0.1N HCl so that its active hydrogen becomes available for binding. The acidified drug is then extracted into chloroform and recrystallized. To form the drug–lipid complex, the drug acid and lipid (in chosen molar ratios) are accurately weighed, dissolved in solvents like dichloromethane or methanol, and refluxed for about an hour. After that, the solvent is carefully evaporated under vacuum at 40 °C using a rotary evaporator. Finally, the dried residue is collected and placed in a vacuum desiccator to ensure complete drying.

Hand –shaking method

In the hand-shaking method, the drug and lipid are first dissolved in a solvent like dichloromethane inside a round-bottom flask. The solvent is then gently removed with a rotary vacuum evaporator, leaving behind a thin film coating the flask walls. When this film is mixed with warm water (50–60 °C), it swells up and forms tiny vesicles, resulting in a suspension.

Ether injection method

In this method, the drug–lipid solution in diethyl ether is slowly injected into hot water (55–65 °C) under reduced pressure. As the ether vaporizes, vesicles are formed [7]

Supercritical fluid process

In the supercritical fluid method, the drug–lipid complex is mixed with supercritical carbon dioxide and then passed through a nozzle into a chamber. The rapid mixing and turbulence create high supersaturation, leading to quick dispersion and pharmacosomes.

Characterization of Pharmacosomes

To understand pharmacosomes better, different tests are done

- **Complex Formation** FTIR is used to check if the drug and lipid have truly bonded by comparing with their individual spectra.
- **Surface Morphology** SEM and TEM give clear images of their size and shape, which can change depending on preparation conditions.
- **Solubility** Their solubility is tested in buffers of different pH levels and organic solvents at body temperature, then analysed with HPLC or UV. [8]
- **Crystallinity (XRPD)** Shows whether the drug remains crystalline or becomes more amorphous inside the complex. [9]
- **Drug Content** Measures how much drug is actually loaded into the lipid using UV spectrophotometry.
- **DSC** Detects drug–lipid interactions by looking at changes in thermal behaviour.
- **FTIR (again)** Also helps monitor the stability of pharmacosomes over time.
- **In vitro Drug Release studies** In vitro drug release is commonly studied using **Franz diffusion cells**, where pharmacosomal gels are placed in a donor compartment separated from the receptor medium (pH 7.4 buffer at 37 °C) by a dialysis membrane, and samples are analysed over time. Another method is the reverse dialysis bag technique, where pharmacosomes are enclosed in dialysis bags placed in the medium. This approach increases membrane surface area, improves drug transport, and reduces experimental steps, making it more efficient.

Applications of Pharmacosomes[10]

- Pharmacosomes are more stable and long-lasting than many other delivery systems.
- They can carry medicines directly to the target site, making treatment more effective.
- Useful for delivering peptides, proteins, and even eye medicines, where they improve drug absorption through the cornea.
- Can be further improved using techniques like PEGylation and biotinylation.
- Help researchers study how drugs actually work inside the body.
- Boost the effectiveness of natural compounds like flavonoids and glycosides.
- Proven to enhance the performance of drugs such as pindolol, bupranolol, taxol, and acyclovir.
- Can transport essential biomolecules like proteins and amino acids.
- Have wide applications across many medicines NSAIDs, antifungal, anticancer, antiviral, antihypertensive, diuretics, and even nucleic acids.

Marketed Preparations[11]

- **Human use** Pharmacosomes are used to make low molecular weight Iron Dextran, marketed as CosmoFer®, the only injectable iron product. It can be given as a total dose infusion, or through intravenous and intramuscular injections, offering flexibility in treating iron deficiency.
- **Veterinary use** In animals, Iron Dextran is widely used as a supplement to prevent iron deficiency anaemia in piglets. Drug products like Uniferon® are already available in many countries for animal use.

CONCLUSION

Pharmacosomes can encapsulate a wide variety of drugs and offer several benefits, such as better solubility, improved stability, reduced toxicity, and controlled drug release. They are versatile enough to carry both water-loving (hydrophilic) and fat-loving (lipophilic) drugs. When the drug forms a covalent bond with the carrier, the entrapment efficiency increases. By reducing harmful side effects and enhancing therapeutic outcomes, pharmacosomes can significantly improve drug performance. In addition, biodegradable micelle-forming drug conjugates can increase the hydrophilicity of certain drugs, making them easier to deliver. Overall, pharmacosomes are a promising and powerful drug-delivery system, with the potential to treat a wide range of diseases more effectively than traditional delivery methods.

Future prospective

Like other vesicular drug delivery systems, pharmacosomes also face certain limitations. However, they play a vital role in targeted and controlled drug delivery, often showing clear advantages over other vesicular carriers. To further improve their effectiveness, factors such as spacer groups and chemical linkages need to be studied more closely, as these can greatly influence the drug's stability, activity, and overall therapeutic outcome. More research is also required to understand non-bilayer phases and the exact mechanisms by which pharmacosomes work. One of their major strengths is their high entrapment efficiency, with the added benefit that drug delivery can be precisely planned, since the drug itself forms vesicles when combined with lipids. Given their strong potential, deeper research and development are essential to unlock more meaningful results from this system.

ACKNOWLEDGEMENT

We express our sincere thanks to Dr. L. Rathaiah, Chairman, Vignan Group of Institutions for providing necessary facilities to carry out the above review.

Table 1: Application of Pharmacosomes delivering various drugs:[12-28]

S.No	Drug	Used Solvent	Method	Outcome
1	Aceclofenac	Dichloromethane	Solvent evaporation	Improved solubility & dissolution profile
2	Acyclovir	water	Tetrahydrofuran	Stability from heat,absorbed by plasma protein in blood and reduced hemolytic reaction
3	Amlodipine	Dichloromethane	Solvent evaporation technique	Sustained drug release
4	Aspirin	Dichloromethane	Solvent evaporation method	Improved solubility and bioavailability
5	Baicalein	Tetrahydrofuran	discontinuous solvent evaporation method	Improved bioavailability
6	Bupranolol hydrochloride	Water	covalently linked to 1, 3-dipalmioyl-2-succinyl-glycerol	Enhanced effect on intra ocular pressure in rabbit
7	Capsaicin	Ethanol	solvent evaporation technique	Showed greater cytotoxicity and potential barrier for cancer therapy
8	cholesterly–adipoyldidanosine	water	Tetrahydrofuran injection method	Improved stability

	(CAD)			
9	Diclofenac	Dichloromethane	Solvent evaporation	Improved solubility and dissolution profile
10	Didanosine	water	Tetrahydrofuran injection	liver targeting andsustained-release effect in the target tissues
11	Etodolac	Acetone, dichloromethane, methanol	Thin film hydration	Increased solubility, entrapment efficiency and sustained drug release
12	Furosemide	Methyl alcohol	Vacuum evaporation	Improved solubility and bioavailability
13	Geniposide	Tetrahydrofuran	Vacuum evaporation method	Increase in absorption and permeability
14	Ibuprofen	Ethanol	Solvent evaporation method	Improved solubility and dissolution profile
15	*Kaempferia galangal* rhizome extract	Ethanol	Conventional solvent evaporation method	Improved bioavailability and analgesic activity
16	Ketoprofen	Dichloromethane	Conventional solvent evaporation method	Improved solubility and bioavailability
17	Naproxen	Diethyl ether, ethanol, acetone	Ether injection method	Enhancement of solubility and controlled drug release
18	Naringenin	Dichloromethane	Solvent evaporation technique	Improved bioavailability
19	Nimesulide	Dichloromethane	Solvent evaporation method	Improved solubility and dissolution profile
20	Ornidazole	Dichloromethane, di ethyl ether	Solvent evaporation method, ether injection method	Sustained drug release and improved bioavailability
21	Pindololdiglyceride	Acetone, dichloromethane	Thin film hydration method	Three to five times increase in plasma concentration and lower renal clearance
22	Piroxicam	Chloroform	Solvent evaporation technique	Improved bioavailability
23	Quercetin	Dichloromethane	Solvent evaporation technique	Improved solubility by 12 folds
24	Rosuvastatin	Chloroform, dichloromethane	Solvent evaporation	Sustained drug release and improved bioavailability

ABSTRACT

Pottali Kalpana/rasayana is one among the *chaturvidharasayana*. *Lokanatha Rasa* is one such formulation which is *Sagandha Sagni Murchitha Parada yoga*. It is a herbo-mineral *Ayurvedic* formulation used to manage *Atisara, Yakrut-pliharoga* and other Gastrointestinal disorders. To compile references of *Lokanatha rasa* from *Bhaishajya Ratnavali*, a renowned *Ayurvedic* text and to review the therapeutic properties of *Lokanatha Rasa*. Highlighting four variations of *Lokanatha Rasa* with differing ingredients and preparation methods from *Bhaishajya Ratnavali.* The formulation's efficacy in treating *Atisara* (diarrhea), *Yakrut-pliharoga* (liver-spleen disorders), *Gulma* (abdominal lumps), And Udara (abdominal diseases) is attributed to its *Deepana-Pachana, Lekhana,* and *Rasayana* properties. The presence of *Kaparda, Kajjali, Abhraka, Tamra,* and *Loha bhasma* in *Lokanatha Rasa* aids in balancing *Agni* (digestive fire) and regulating *Pitta dosha*. This review provides insights into the formulation's probable mode of action, highlighting its potential in managing *Atisara* and *Yakrut-pliharoga. Lokanatha Rasa* is a potent herbo-mineral formulation that can be used to manage Gastrointestinal disorders and *Yakrut-pliharoga*. Its unique preparation method and combination of ingredients make it a significant formulation in *Ayurvedic* medicine.

Keywords: *Lokanatha Rasa, Bhaishajya Ratnavali, Atisara, Yakrut-pliharoga***.**

INTRODUCTION

Rasashastra the special branch of Ayurveda which deals with the use of certain minerals, metals and other organic and inorganic substances in the treatment of diseases. The different methods of preparation and administration of rasa dravyas are known as Chaturvidha rasayana. Lokanatha Rasa is one such formulation which is Sagandha Sagni Murchitha Parada yoga. First reference of Pottali Kalpana was found in Rasaratnakara written by Acharya Nityanatha during 12th century, where Ratna Garbha pottali and Shanka Garbha pottali has been mentioned. Based on preparation, pottali rasayana has been classified into Bhavana method, Putapaka method, Gandhaka drava paka method and Kapardha poorna method [1]. Lokanatha Rasa is claimed to be significant in the management of Gastrointestinal disorders such as atisara, yakrut-pliha roga, gulma, udara etc, as it has Kaparda Bhasma as one of the main components of the formulation, it is significantly useful in managing these disorders by balancing agni. Bhaishajya Ratnavali written by Kaviraj Govinda das Sen in 18th century AD has been the most popular Ayurvedic classics among the Ayurveda practitioners which has compilation of formulations from Chakradatta, Rasendra Sara Sangraha (RSS), Charaka Samhitha etc [2]. In Bhaishajya Ratnavali 4 varieties of Lokanatha Rasa has been mentioned in different context. This article aims at compiling all the references of Lokanatha Rasa mentioned in Bhaishajya Ratnavali in different context.

MATERIALS AND METHODS

Atisara Chikitsa Parakarana
Name: LOKANATHA RASA [3]

Ingredients
Parada Bhasma- 1 part
Shuddha Gandhaka- 4 parts
Shoditha Kaparda- as required
Shuddha Tankana- Quantity sufficient
Honey: Quantity sufficient

METHOD OF PREPARATION

One part of Parada Bhasma along with 4 parts of Shuddha Gandhaka are triturated well to form Kajjali. This Kajjali is filled in Shoditha Kaparda, the slit is sealed by the paste of Shuddha Tankana and honey. Kapardika containing Kajjali is kept in a Sharava Samputa and Sandhi bandhana is done and subjected for Gajaputa. After swanga sheeta of sharava samputa, sandhi bandhana is removed the contents (Kapardika with Kajjali) inside it are pounded together and stored in an airtight container.
DOSE: 4 Gunja
ANUPANA: Honey followed by Kashaya of Ardraka, Ativisha, Musta, Devadaru and Vacha (equal quantity).
INDICATION: Sarva Atisara
The below mentioned all the references of LOKANATHA RASA in Plihayakrut roga chikitsa prakarana follows the Putapaka method of Pottali kalapana for the preparation.

Plihayakrutroga Chikitsa Parakarana
Name: LOKANATHA RASA [4]

Ingredients
Shuddha Parada - 1 part
Shuddha Gandhaka- 1 part
Abhraka bhasma- 1 part

Loha bhasma- 2 parts
Tamra bhasma- 2 parts
Kaparda bhasma- 3 parts
Nagavalli swarasa- Quantity sufficient

Method of Preparation
1 part each of Shuddha Parada and Shuddha Gandhaka are triturated well to form Kajjali. Later along with Kajjali, mentioned quantity of other Bhasmas are taken in khalva yantra and subjected for bhavana with Nagavalli swarasa and chakrikas are prepared. In sharava samputa these chakrikas are placed and sealed before subjecting them to puta, later subjected to laghu puta.

Anupana
Maricha churna + Honey
Haritaki churna + Guda
Ajaji + Guda
INDICATION: Yakrut-Pliha roga, Gulma, Udara, Jeerna jwara, Pandu, Kamala, Shvayatu, Agnimandya

Plihayakrutroga Chikitsa Parakarana
Name: LOKANATHA RASA SWALPA [5]

Ingredients
Shuddha Parada - 1 part
Shuddha Gandhaka- 1 part
Abhraka bhasma- 1 part
Loha bhasma- 2 parts
Tamra bhasma- 2 parts
Kaparda bhasma- 4 parts
Nagavalli swarasa- Quantity sufficient

Method of Preparation
Kajjali along with mentioned quantity of other Bhasmas are taken in khalva yantra and subjected for bhavana with Nagavalli swarasa for 1 prahara (3 hours) and chakrikas are prepared. In sharava samputa these chakrikas are kept inside and sealed before subjecting them to puta, later subjected to laghu puta.

Dose: 2 Gunja
Anupana: Ardraka swarasa followed by Khadira twak kashaya
Indication: Yakrut-Pliha roga, Udara, Sarva Jwara, Shotha, Agnimandya

Plihayakrutroga Chikitsa Parakarana
Name: LOKANATHA RASA BRUHAT [6]

Ingredients
Shuddha Parada - 1 part
Shuddha Gandhaka- 2 parts
Abhraka bhasma- 1 part
Loha bhasma- 2 parts
Tamra bhasma- 2 parts
Kaparda bhasma- 9 parts
Kumari swarasa- Quantity sufficient
Kakamachi swarasa- Quantity sufficient

Method of Preparation
One Part Shuddha Parada and 2 parts Shuddha Gandhaka along with one-part Abhraka bhasma are taken in khalva yantra and subjected for bhavana with Kumari swarasa. After bhavana mentioned quantity of Tamra bhasma, Loha bhasma and Kaparda bhasma are added to the prepared mixture and again subjected for bhavana with Kakamachi swarasa and chakrikas are prepared. In sharava samputa these chakrikas are kept inside and sealed before subjecting them to puta, later subjected to laghu puta.

Dose: 2 Gunja
Anupana: Honey
Indication: Yakrut-Pliha roga, Kamala, Jeernajwara, Gulma

Probable Mode of Action7]

OBSERVATION

By assessing the rasa panchaka of the above ingredients as they possess actions like Deepana, Rasayana, Vyavayi hence indicated in Gastrointestinal disorders like Atisara, Grahani etc. There are many references found in classics by the name of Lokanatha Rasa, but the ingredients and method of preparation varies from one another. In Bhaishajya Ratnavali 4 varieties of Lokanatha Rasa has been mentioned. First reference is mentioned in Atisara chikitsa prakarana sourced from Rasendra Sara Sangraha which follows Kaparda poorna method and 3 references are mentioned in Plihayakrut roga chikitsa prakarana which follows bhavana followed by Putapaka method. These 3 references differ only in the quantity of kaparda Bhasma and bhavana Dravya used. In preparation of Lokanatha Rasa Swalpa the time for bhavana has been mentioned as 1 prahara (3 hrs). According to Rasa Yoga Sagara 15 variants of Lokanatha Rasa has been mentioned including Lokanatha pottali, Lokeshwara rasa etc. In AFI (Part I) the reference of Lokanatha Rasa is from Rasendra Sara Sangraha Pliha Chikitsa.

DISCUSSION

Lokanatha Rasa mentioned in Bhaishajya Ratnavali has 4 references under different prakaranas among them first reference is mentioned in Atisara chikitsa prakarana and other 3 references are mentioned in Plihayakrut roga chikitsa prakarana. Lokanatha Rasa having Kaparda ($CaCO_3$) as major ingredient helps in reversing both secretory and inflammatory diarrhoea. It also acts as functional nutrients which is required as there is divalent mineral loss in diarrhoea. And play a crucial role in managing the gut lining, regulating muscle contractions, and exhibiting anti-secretory effects [8]. Lokanatha Rasa mentioned in Atisara chikitsa prakarana in which anupanas like Ardraka and Musta serves as effective Grahi, helping to alleviate Atisara by absorbing excess fluids and stabilizing bowel movements along with main ingredients. In Lokanatha Rasa Swalpa, it's been told to use Ardraka swarasa and Khadira twak Kashaya as anupana. Khadira twak due to its anti-inflammatory, antioxidant and hepatoprotective properties helps in effective management of splenomegaly, hepatotoxicity and related disorders such as anaemia and liver disorders [9]. Nagavalli swarasa as bhavana Dravya, is rich in piperine and flavonoids exhibits potent hepatoprotective activity through its lipid peroxidation-inhibiting properties. Kakamachi swarasa possess hepatoprotective property due to its bioactive compounds like solasodine and flavonoids [10]. Kumari swarasa is yakrit uttejaka (liver tonic), effective in liver diseases. Due to Lekhana, Pleehahara, Rasyana, Yogavahi, Pittahara properties of Tamra and Loha, it helps in regulation of pitta dosha and Lekhana of sookshma srotas. Hence useful in Yakrut vriddhi and Pliha vruddhi.

CONCLUSION

Lokanatha Rasa is a unique herbo-mineral preparation which aids in treating Atisara and Pliha Yakrut vikara by balancing agni. Bhaishajya Ratnavali, an Ayurvedic classics which has been followed by all the Ayurvedic practitioners describes Lokanatha Rasa as a Potent formulation. Lokanatha Rasa is a potent Ayurvedic formulation aimed at managing Atisara and related disorders like splenomegaly and hepatotoxicity. The inclusion of Kaparda (Calcium Carbonate) helps regulate gut motility, reduces inflammation, and replenishes essential minerals lost during diarrhoea. The use of anupanas like Ardraka and Musta further supports digestive health by absorbing excess fluids and stabilizing bowel movements. Additionally, bhavana dravyas such as Nagavalli Swarasa and Kakamachi Swarasa provide hepatoprotective benefits, supporting liver function. Kumari Swarasa enhances detoxification and acts as a liver tonic. The metals Tamra and Loha help regulate Pitta dosha, treat liver disorders, and improve overall metabolic balance. This formulation is comprehensive, combining herbal and mineral ingredients to address both gastrointestinal and liver health, making it effective in treating diarrhoea and its complications. ABSTRACT

In this paper, we discuss some of the important remarks in an Almost quasi-semilattice. The concept of an Almost quasi-semilattice was already introduced by E.A.Geoferlin Jesho and Dr.A.Pramila Inpa Rose. In this paper, we prove some theorems with suitable examples on Almost quasi-semilattice. Further, we derive some conditions based on the ideals of Almost quasi-semilattice. Also, the definition of an Almost quasi-semilattice with zero is discussed with related examples. Moreover, the remarks and results on almost quasi-semilattice are discussed with examples.

Keywords: Semilattice, Almost semilattice, quasi-semilattice, Almost quasi-semilattice.
2020 Mathematics Subject Classification (AMS): 06A12, 20M10.

INTRODUCTION

The concept of semilattice was introduced by F.Klein in 1939. In 2017, Nanaji Rao, G. and Terefe Getachew Beyene [5] introduced the concept of an Almost Semilattice (ASL) which is a generalization of semilattices.As a generalization of semilattices, an algebraic system that do not satisfy the association law is called quasi-semilattice if it is idempotent, commutative with respect to the binary operation [8].Naturally, whether the associative law is satisfied or not is the fundamental difference between semilattices and quasi-semilattices. The concept of Almost quasi-semilattice was introduced by E.A.Geoferlin Jesho and Dr.A. Pramila Inpa Rose [2] . Ideals were first studied by Dedekind, who

defined the concept for rings of algebraic integers. In this paper, we discuss some of the results and remarks of order relation and ideals in an Almost quasi-semilattice. Also, we derive theorems with few examples and some properties on it.. Also, we define the definition for an almost quasi-semilattice with zero and we give examples for it. Moreover, we prove some important lemmason order relation and ideals in an almost quasi-semilattice.

PRELIMINARIES

Definition 2.1. Let A and B be the non-empty sets. A relation R from A into B is a subset of A×B. Relations from A into A are called relation on A.

Definition 2.2.A partially ordered set or simply a poset, we mean a non empty set P together with an ordering $\leq$, which satisfying the following;
(1) $x \leq y$, for all $x \in P$ (reflexive)
(2) For any $x, y \in P$, $x \leq y$ and $y \leq x$ implies $x = y$ (anti-symmetric)
(3) For any $x, y, z \in P$, $x \leq y$ and $y \leq z$ implies $x \leq z$ (transitive).

Definition 2.3. A partially ordered set or simply a poset $(P, \leq)$ is called a lattice if l.u.b.{x,y} and g.l.b. {x,y} exist for all $x,y \in P$.

Definition 2.4.A semilattice S is a nonempty set and $\circ$ is a binary operation on S satisfying:
1. $x\circ (y\circ z) = (x\circ y) \circ z$ (Associative law)
2. $x\circ y = y\circ x$ (Commutative law)
3. $x\circ x = x$, for all $x , y, z \in S$. (Idempotent law)

Definition 2.5.[8] A nonempty set S together with a binary operation $\circ$ is called a quasi-semilattice if for any $a,b \in S$,
- $a\circ a = a$ (Idempotent Law)
- $a\circ b = b\circ a \in S$, (Commutative Law)
- There exist $a,b,c \in S$ such that $(a\circ b) \circ c \neq a\circ (b\circ c)$. (Non Associative Law)

Definition 2.6. [5] An Almost Semilattice $(L,\circ)$ is a non-empty set and $\circ$ is a binary operation on L, satisfies the following conditions:
(1) $(x\circ y)\circ z = x\circ(y\circ z)$ (Associative Law)
(2) $(x\circ y)\circ z = (y\circ x)\circ z$ (Almost Commutative Law)
(3) $x\circ x = x$, for all $x, y, z \in L$. (Idempotent Law)

Theorem 2.7. [2] Let S be an Almost quasi-semilattice. Then, the relation $\leq$ is a partial order relation on S.

MAIN RESULTS

Defintion 3.1.[2] A non empty set S together with a binary operation $\circ$ is said to be an Almost quasi-semilattice if the following axioms hold:
(i) $(x\circ y)\circ z = (y\circ x)\circ z$ for $x, y, z \in S$ (Almost commutative law)
(ii) $x\circ(y\circ z) \neq (x\circ y)\circ z$. (Non Associative law)
(iii) $x\circ x = x$ (Idempotent law)
Defintion 3.2.[2] Let S be an Almost quasi-semilattice . If for any $a,b\in S$, we say that a is less or equal to b and write $a\leq b$, if $a\circ b = a$.

Lemma3.3. Let S be an Almost quasi-semilattice and $\circ$ is a binary operation on S .For any a, b, c, $d\in S$,
i. If $a\leq b$and $a\leq c$, then$a\circ c \leq b$.

ii. If $a \le b$ and $b \le c$, then $a \le b \circ c$.
iii. If $a \le b$, $a \le c$ and $b \le d$, then $a \circ c \le b \circ d$.
iv. If $a \le b$, then $(b \circ a) \circ b = a \circ (a \circ b)$.
v. If $a \le b$, then $a \circ a \le b$.

Proof . Let $a, b, c, d \in S$.
i. Now, $a \le b$, if $a \circ b = a$ and
$a \le c$, if $a \circ c = a$
Consider, $(a \circ c) \circ b = a \circ b = a$
$= a \circ c$.
Therefore, $a \circ c \le b$.
ii. Now, $a \le b$, if $a \circ b = a$ and
$b \le c$, if $b \circ c = b$.
Consider, $a \circ (b \circ c) = a \circ b$
$= a$.
Therefore, $a \le b \circ c$.
iii. Now, $a \le b$, if $a \circ b = a$,
$a \le c$, if $a \circ c = a$ and
$b \le d$, if $b \circ d = b$.
Consider, $(a \circ c) \circ (b \circ d) = a \circ b$
$= a$
$= a \circ c$.
Therefore, $a \circ c \le b \circ d$
iv. Now, $a \le b$, if $a \circ b = a$
Consider, $(b \circ a) \circ b = (a \circ b) \circ b$
$= a \circ b$
$= a$
$= a \circ a$
$= a \circ (a \circ b)$
Therefore, $(b \circ a) \circ b = a \circ (a \circ b)$.
v. Now, $a \le b$, if $a \circ b = a$
Consider, $(a \circ a) \circ b = a \circ b$
$= a$
$= a \circ a$
Therefore, $a \circ a \le b$.

Lemma3.4 Let S be an Almost quasi-semilattice and $\circ$ is a binary operation on S .For any $a, b \in S$ and $a \le b$ and $b \le a$, then a=b.

Proof . Let $a, b \in S$.
Now, $a \le b$, if $a \circ b = a$ and $b \le a$, if $b \circ a = b$.
Consider, $a = a \circ a$
$= (a \circ b) \circ a$
$= (b \circ a) \circ a$
$= b \circ a$
$= b$
Therefore, a=b.

Defintion 3.5.A non empty set S together with a binary operation $\circ$ is said to be an Almost quasi-semilattice with zero if the following axioms hold:

i. $(x \circ y) \circ z = (y \circ x) \circ z$ for $x, y, z \in S$ (Almost commutative law)

ii. $x \circ (y \circ z) \neq (x \circ y) \circ z$. (Non Associative law)
iii. $x \circ x = x$ (Idempotent law)
iv. $0 \circ x = 0$

Lemma3.6. Let S be an Almost quasi-semilattice with 0 and ◦ is a binary operation on S. If $a \leq b$ and $b \leq a$, then $a \circ b = 0$ if and only if $b \circ a = 0$.

Proof . Let $a, b \in S$.Now, $a \leq b$, if $a \circ b = a$ and $b \leq a$, if $b \circ a = b$.
Suppose, $a \circ b = 0$.
Then, $b \circ a = (b \circ a) \circ a$
$= (a \circ b) \circ a$
$= 0 \circ a$
$= 0$
(i.e) $b \circ a = 0$.
Conversely, suppose $b \circ a = 0$.
Then, $a \circ b = (a \circ b) \circ a$
$= (b \circ a) \circ a$
$= 0 \circ a$
$= 0$.
(i.e) $b \circ a = 0$.
Remark 3.7.. Let S be an Almost quasi-semilattice with 0 and ◦ is a binary operation on S. If $a \leq b$ and $b \leq a$, then $a \circ b = b \circ a$.
Obviously, the proof follows from lemma 3.6.

Definition 3.8. Let S be an Almost quasi-semilattice and ◦ is a binary operation on S.A non empty subset I of an S is said to be an ideal if $x \in I$ and $a \in S$, then $x \circ a \in I$.
Example 3.9. Let S = {0, a, b, c}. Define a binary operation ◦ on S as follows:

◦	0	a	b	c
0	0	0	0	0
a	0	a	a	c
b	0	c	b	a
c	0	c	a	c

Here, S is an almost quasi-semilattice with zero.
Now, I={0,a,b} is closed under the operation ◦, but is not an ideal, since $a \circ c = c \notin \{0,a,b\}$.

Example 3.10. Let S = {0,a, b, c,d}. Define a binary operation ◦ on S as follows:

◦	0	a	b	c	d
0	0	0	0	0	0
a	0	a	a	a	b
b	0	a	b	c	b
c	0	a	a	c	b
d	0	c	b	b	d

Then, S is an almost quasi-semilattice with zero.
Now, I={0,a,b} is closed under the operation ◦, then I is an ideal of S.
Remark 3.11. Let S be an almost quasi-semilattice with 0. If I and J are the ideals of S, then the union of I and J is also an ideal S.

Example 3.12. Let S = {0, a, b, c}. Define a binary operation ◦ on S as follows:

◦	0	a	b	c
0	0	0	0	0
a	0	a	a	c
b	0	c	b	a
c	0	c	a	c

Then, S is an almost quasi-semilattice with 0.
Here, I = {0,b} and J = {0, b, c} are the ideals of S.
Now, I∪J = {0, b, c}, which is an ideal of S.

Remark 3.13. Let S be an almost quasi-semilattice with 0. If I and J are the ideals of S, then the intersection of I and J is also an ideal of S.
From example 3.12,
I∩J = {0, b}, which is an ideal of S.

CONCLUSION

In this paper, we discussed some of the properties of an almost quasi-semilattice. Also, we define almost quasi-semilattice with zero with suitable examples and theorems. Moreover, we discussed some examples, remarksand theorems based on order relation and ideals in an almost quasi-semilattice.

ABSTRACT

The financial services industry in India has undergone significant changes since deregulation. Economic growth, job creation, productivity, and living standards have all been enhanced as a result of India's openness to foreign trade. These innovations enabled individuals to earn more money, which in turn gave them more disposable income. The primary objectives of this study are to understand the current gold investment patterns of Middle-income investors, to analyze the impact of Demand factors on the Gold Investment Decisions of middle-income investors, and to examine the impact of Supply factors on the Gold Investment Decisions of Middle-income Investors. The study focuses on middle-income investors in Bangalore city, employing a quantitative analysis approach. The researcher employs the Survey method as a study strategy to gather data from middle-income investors. The sample size used in the study comprises 154 middle-income investors from Bangalore city. The study utilized SPSS Version 22 and AMOS Version 22 software for data analysis.

Keywords: Demand, Financial services, Foreign Trade, Gold Investment Decision, Supply

INTRODUCTION

The financial services industry in India has changed drastically since deregulation. Economic growth, job creation, productivity, and living standards have all been enhanced as a result of India's openness to foreign trade. These innovations allowed individuals to make more money, which meant they had more money to spend. Increasing

investment was the sole option for putting this surplus capital to work, as it would generate new economic prosperity (Mamcarz, K., 2015).Spending money on something with the hope of earning interest or seeing its worth increase in the future is called investing. In financial parlance, "savings" is defined as the sum that remains after deducting expenditures from revenue. Some of these reasons include: a down payment on a house or vehicle, jewelry, a child's education, a comfortable retirement, emergency expenses (such as medical bills or lost wages), and so on. Without wise investment, one's wealth will not grow. Citizens' inclination to conserve money is driving rapid economic growth in China, India, Indonesia, Malaysia, Singapore, South Korea, and Thailand. (Verma, S., & Sharma, M., 2014).

For as long as there have been humans, gold has been a store of value. Its value as a medium of exchange, investment, reserve asset, accoutrement, and part of technology ranges widely. Its value has been maintained throughout time due to its historically low supply and high liquidity. During times of market volatility, it helps to distribute risk and lessens harm. For quite some time, gold has captivated academics, central bankers, and corporate executives alike.(Baber, P., et al.,2013). The devotion of the Indian people to the precious metal is a tale that spans millennia. Over the span of many thousand years, India has been governed by a great many dynasties and monarchs, bringing with them a great many conflicts, conquests, and political revolutions. The monetary systems of many kingdoms across the subcontinent relied on gold as a medium of commerce or store of value(Coulson, M., 2005). This helped to preserve riches during the many wars and changes in rulers that occurred over the ages. In India, gold is more than just a precious metal; it has profound religious significance and is a symbol of national pride. Because of its inherent holiness and the fact that it underwent a process of development that included passing through fire, gold is an integral component of all religious rites and ceremonies. Affluence and prosperity are indicated by it. Millions of people from every corner of the globe are drawn to this brilliant yellow metal. It is an essential part of most Indian households. Seen as a sign of abundant prosperity and joy. It is customary to mark important life milestones, cultural celebrations, and festivals with a gold adornment (Street, L., et al., 2015).

Many people buy gold as a safety net in case the economy crashes or if the price of other assets goes up or down too much. Protecting one's money is of the utmost importance in light of the current financial market's high volatility. When deciding where to place their money, people are more concerned with the investment's stability and its prospective profitability. For all its "refined delight, elegance, and of things desirable but not required" qualities, gold jewelry is the quintessential luxury good. Because they usually include a name-brand item meant to boost the wearer's status, jewelry and accessories are also called luxury products.

Real estate and capital markets have failed to impress since demonetization and the implementation of GST in 2016–17, leading some to view gold as a safer investment option. As a result, the demand for the precious metal in India has increased (Johan, Z. J., 2020). Despite fluctuations in gold prices caused by the COVID-19 pandemic, the metal's long-term worth did not change. Low yields (interest rates) on bonds and other competing assets have hurt gold investments, but the price of gold has only increased. The COVID-19 pandemic has caused investors to shun fixed deposits in favor of assets linked to gold(Demidova-Menzel, N., & Heidorn, T, 2007). A considerable number of Indians fall into the middle class. At the National Council for Applied Economic Research's Centre for Macro Consumer Research, they project that "by 2025-26 the number of middle class households in India is likely to more than double from the 2015-16 levels to 113.8 million households or 547 million individuals." (Tandon, V., & Mistry, D. S., 2022). With this background the current study aims to conduct a research on the - *"Impact of Demand and Supply Factors on the Gold Investment Decision of Middle Income Investors"* The study's justification is provided in the first part. The review of the literature is the main topic of the second segment. The third portion contains information on the research methodologies, while the fourth section contains the study's findings. This study's final part offers its limits and areas for future investigation.

Theoretical Framework

In order to assess background reviews and independent research relevant to the Gold investment, supply, and demand aspects, the study used a systematic literature review process. Based on the requirement that only English

studies published during the last five years be included, a total of 54 papers were found and chosen for inclusion in the review. After acquiring the full text of the corresponding research works, a total of 44 literary works were chosen in order to perform an extensive assessment of their quality. Because of their quality problems and iterative procedures, four research were not included in the study. The current investigation is based on an extensive analysis of forty pertinent academic publications. Each study's quality level was assessed by carefully examining the publications, which were taken from reputable journals. Taylor & Francis database, Elsevier database, and Routledge and CRC Press database. databases from Sage, Springer Nature, and Emerald Group Publishing. A number of additional papers were obtained from respected scholarly databases, including Wiley, Academia, JSTOR, and Guildford Press.

LITERATURE ANALYSIS

Gold investments

Over the past few years, gold investments in India have been becoming more and more popular. The principal reason is the role gold plays in Indian culture, not to mention the fact that it is viewed as being a fixture of stability for investing (Napompech, K., et al., 2010). To guard against economic uncertainty, many Indians consider gold a safe haven asset for boosting their investment portfolios (Ahmad Fauzi, et al., 2017). Additionally, the Indian government has implemented policies to stimulate gold investment. With the Gold Monetization Scheme and other programs, this too has further increased interest in the precious metal(Fening, P. A., et al., 2022). The Indians are very fond of gold for its historical and cultural significance as well as for the belief that the metal maintains itself well (Hemalatha, S., 2019). Moreover, gold is a status symbol in Indian society; so people further made it into an investment option. Indian investors continue to cling to this precious metal as a means of protecting their wealth and diversifying their portfolios benefiting from the government's support and policies encouraging gold investments (Luo, J. , 2021). As a safe haven against economic uncertainties, gold is also attractive to Indian investors. In addition, it is easy to convert into money when needed and can actually be taken home; the inhabitants of India have readily accepted it as an investment method (Anggara, R. (2022). With the burgeoning demand for gold in India, there has been a perceptible shift among investors toward diversifying their portfolios and protecting their wealth. The future of gold investments in India is bright with the continued support of the government. (Kakkar, S., &Chitrao, P. V. , 2021).

Gold investment by middle class investors

The solid middle class is pouring money into gold investments in a bid to diversify portfolios and hedge against inflation(Rahmansyah, I. C., & Rani, L. N., 2021). As the value of gold has always risen over time, many are considering it a safe haven for their earnings (Nawaz, M. S., et al.,2020). Also, investment in gold can give people a greater sense of security upon economic uncertainty in times, making this option attractive to anyone who wants to ensure some measure of security for their future(Chaisuriyathavikun, N., &Punnakitikashem, P., 2016). In India, many of the low -income earners have savings (Zaware, N. 2021). They are more inclined to put money in gold due to its stability and steady – at least, relative to other things. Gold investment is also popular with middle-income people because its cultural significance means that it is often regarded as an emblem of wealth. Many people see gold as an asset that can be turned into cash quickly if necessary, giving them some measure of certainty and mobility in how they invest (Alfianto, A. N., & Nugroho, A. P. , 2020). To close, gold investments are a reliable investment choice for those who are trying to build and safeguard their inheritance over the long-term. (Garg, S., 2021).

Gold investments – Demand and Supply factors

The personal demand factors for gold investments include economic conditions, inflation rates, and political stability (Jeuland, M., et al., 2021). People investing in gold also consider their risk tolerance, investment purposes, and time frames. Apart from this, you go on to say that market trends (e.g. gold prices and demand) may also sway whether individuals choose to invest in metals (Amirthalingam, S., & Geetha, R., 2023). In short, the personal demand factors for gold investments are more varied and complex than that. People's thirst for gold as a safe haven asset can rise in

times of global economic uncertainty or political upheaval, but low inflation rates do not make gold appear any more attractive (Ajeesh, A, 2022). For some investors, gold's long-term potential to hold its value and hedge against market volatility may be worth more than the short-term price movements (Auxilia Felicitas, A I, 2010). In the endonly investors can separate out on that personal side according to individual criteria whether gold should or shouldn't be invested into their portfolios. (Bhuvaneswari, GG, 2015)

Research Gap

A large number of researches have been done on attitudes a gold, but there has been lacking research on the middle-income investors' attitudes towards gold. This lack of research is especially alarming since middle-income investors occupy a significant share of the market in gold investment. By understanding their behavior and motivations, we may gain new insights both for investors themselves and for financial institutions. Developing investments and products better tailored to their needs would be a feasible means of doing that. To ensure that middle-income investors can make more informed decisions in gold investment, it is crucial to eliminate this knowledge void.

Research Objectives

- To understand the current Gold investment patterns of Middle income investors
- To analyze the impact of Demand factors on Gold Investment Decision Of Middle Income Investors
- To analyze the impact of Supply factors on Gold Investment Decision Of Middle Income Investors

RESEARCH METHODS

The following research methods are used for the study

The research philosophy under consideration is positivism. The research philosophy of positivism is congruent with the theories on Gold investments . (Alharahsheh, H. H., & Pius, A., 2020).

The research approach employed in this study is a deductive approach. The deductive technique is frequently employed in positivist research due to its reliance on formulating a hypothesis derived from preexisting theories, followed by empirical testing through data gathering and subsequent analysis. (Casula, M., Rangarajan, N., & Shields, P., 2021).

RESEARCH METHODOLOGY

Mono method quantitative analysis. The study focuses on middle income investors in Bangalore city, employing a quantitative analysis approach. In order to acquire quantitative data, the researchers sent out surveys to Middle income investors. (Manzoor, A., 2020). The researcher employs the Survey method as a study strategy to gather data from middle-income investors. The survey comprises inquiries pertaining to the demand factors, supply factors and investment decision. A well-structured questionnaire was prepared by referring to the previous articles. (Dawson, M., Abbott, J., & Shoemaker, S., 2011). The present investigation pertains to a cross-sectional research design. The survey was done by the researcher over a duration of four months in order to collect data from middle income investors in Bangalore city. The chosen timeframe provides an ample sample size and enables the researcher to effectively capture any potential fluctuations in investment decisions that may be influenced by seasonal factors. (Wang, X., & Cheng, Z. ,2020). (Xie, C., et al., 2022). The size of the sample used in the study involves the selection of a sample of 154Middle income investors from Bangalore city, utilizing the Cochran formula to determine the sample size required for a 7.5% margin of error and a 95% confidence level. The unit of analysis for this study are the Middle income investors who have invested independently in gold in the last 5 years . The Middle income investors who were interested to take a brief session on the topic and give their valuable insights were considered for the study. The sample technique employed in this study is non-probability sampling, specifically convenience sampling. The utilization of convenience sampling was justified due to its ability to provide researchers with convenient access to a substantial pool of possible Middle income investors across Bangalore

The validity and reliability ofdata-gathering tool utilized in this study was conducted.
Gliem, J. A., & Gliem, R. R. (2003) provide the following rules of thumb: "_ > .9 – Excellent, _ > .8 – Good, _ > .7 – Acceptable, _ > .6 – Questionable, _ > .5 – Poor, and _ < .5 – Unacceptable". The scores for reliability for all constructs in the Middle income investors ' research instrument were above .9 and below .95 indicating excellent reliability. The inter item correlations between the constructs is tested using the confirmatory factor analysis. The Pearson correlation r value is 0.522 which is well within the criteria to affirm internal consistency. Convergent validity is the assessment of the degree of correlation among various concept indicators that show agreement. The indicator's factor loading, composite reliability (CR), and average variance extracted (AVE) must all be considered in order to determine convergent validity (Hair Jr & et al., 2017). The values are between 0 and 1. It is important for the AVE value to exceed the cutoff point of 0.50 in order to guarantee convergent validity. MaxR(H) - Maximum reliability > than MSV; CR - Composite reliability > than 0.70 (0.898); AVE - Average Variance explained > than 0.50 (0.762); MSV - Maximum shared square variance > than AVE. The Fornell-Lacker criterion is used to assess discriminant validity when applying the second criterion (Fornell, Cha, & Bagozzi, 1994) (Farrell, A. M., & Rudd, J. M., 2009). This method compares the correlation of latent constructs with the square root of the average variance extracted (AVE) (Hair Jr & et al., 2017). A latent construct's ability to explain variance in its own indicators is predicted to be greater than its ability to explain variance in indicators of other latent constructs. Hair Jr. et al. (2017) state that it is expected that the correlations with other latent constructs will be lower than the square root of the average variance extracted (AVE) for each construct. The Middle income investors questionnaire was deemed valid and reliable in the current model since all dimensions have been verified and all constructs meet the validity criteria. The reliability and validity of the questionnaire was tested using the master validity tool by Gaskins and was affirmed. (Shia, T. H., et al, 2023). The study utilized SPSS Version 22 and AMOS Version 22 software for data analysis. Thakkar, J. J., & Thakkar, J. J. (2020).

RESULTS AND DISCUSSION

Demographic profile of the investors

64% Investors in Gold are Women and 36% are Male. 26% Gold investors are in the age group of 18-25 years, 30% are in the age group of 36-45 years, 26% are in the age brackets of 46-55 years and small percent of gold investors are above 55 years. 44% respondents are undergraduates, 14% are Post graduates and 16% have completed their Professional Degree. A large proportion of 56% are married and 44% are unmarried. 40% Gold investors in the study are private sector employees, 30% are Government employees ad 30% own a business. 26% respondents have a monthly income between Rs 60,000 - Rs 1, 20,000. 20% had an income above Rs 1,50,000. About 84% respondents in the study preferred to invest in KDM Gold. 56% respondents purchased Gold as and when funds were accumulated.

Item analysis for Demand and Supply Factors for investment decision

Item analysis refers to the process of understanding the mean, standard deviation, skewness and Kurtosis of the data. It is important to conduct item analysis since they give insight into the quality and reliability of the measurement instrument that is being used. They help in determining if the items are working effectively, if they able to measure what they are supposed to measure and if they function together. It also helps in identifying items that are not performing effectively and need to be revised or dropped to yield a more valid and reliable measurement instrument.

Demands factors mean scores were between 3.84 and 4.18. This shows that investors generally agree on the need factors when investing in Gold. In deciding whether to put money into gold, such factors as global economic conditions, inflation rates, and geopolitical instability are generally taken into account. These results underscore the importance of demand factors in affecting investment decisions. Indeed, there is a great deal of unanimity between investors about the impact of such factors on Gold value. It is a piece of information that could help people to make good decisions about their gold investments. The standard deviation is less than 1.000, which indicates the least deviation in responses. However, in general, investors seem to look upon Gold as a safe haven asset in times of uncertainty. The low standard deviation also suggests strong agreement between investors about the factors influencing the value of Gold. As there is substantial common understanding in this area among those who are

considering investing in Gold, it suggests a valuable, degree of predictability for the precious metal market. In the end, understanding these demand factors and the degree to which investor opinion is in sync can help individuals make better decisions with their Gold investments. For supply factors, the average scores ranged between 3.40 and 4.08, signifying a consensus of supply factors in investing decisions. What this means is that investors generally view supply factors as an important determinant of investment in Gold. A consensus among investors concerning the importance of these factors in decision-making is also seen in these widely agreed upon scores for various supply factors. In general, the results of this study indicate that supply factors were taken into account above everything else when making investment decisions in Gold. The standard deviation is under 1.000, with the lowest variability in responses. So what this actually means is that investors' views on supply factors in Gold investment decisions are not very different from those of their peers. The low standard deviation means that for supply factors investors agree on their importance in the decision-making process. And investors do not agree on (the general level of) importance of these factors. The common ground among investors about supply factors served as an added argument for including these factors in Gold investment decisions. Overall, the data point to an unambiguous trend in terms of supply factors shaping investor behavior in the Gold market.

Item analysis for investment decisions

The average score for the investment decision was greater than four, which suggests that respondents in this study are interested in buying gold in the near future to make a reasonable profit from it. This indicates a positive attitude of investors toward the possible gains and stability of gold investing. The high mean scores also suggest widespread belief in gold as a refuge of investment during economic uncertainty. In general, interest in gold as an investment option is growing among those who responded to this study. The standard deviation is less than 1.000, indicating the least variation in responses. But consistency of response in this way further strengthens the conclusion that investors have confidence in the benefits of investing in gold. Low standard deviation also implied that most respondents' opinions on gold as a plausible investment option were fairly consistent. This information illustrates that gold is recognized as a stable and useful type of asset, especially when markets are volatile and economic conditions are uncertain. Overall, the study points to a stronger preference for gold as an investment strategy among participants.

Testing of Hypothesis

H1 – Demand Factors positively impact the investmentdecision

Within the reasonable range of 3 (more precisely, 2.876), the chi-square divided by degrees of freedom ($\chi 2$ / df) is acceptable. Compared to the suggested characteristics, the actual Goodness of Fit rating (0.826) is superior. The RMR comes out to be 0.048 according to the boundary estimation. Not only does this model have good fit metrics, but it has also received acceptance from academics.

Middle-income gold investors' investment decisions are significantly influenced by demand factors. The investment decision increases by 86.2% as demand factors increase (B=0.862, b=0.921, p=0.000). This was a clear sign that Middle income Gold investors on the whole have substantial dependence on market demand when making investment decisions. The strong relationship between demand factors and investment behavior implies that they watch market trends very closely and change their portfolios with the flow of the market. To Middle income Gold investors, in response to changes in demand conditions, opportunities for growth and high profits can be realized in the gold market with proper management.

H2 – Supply Factors positively impact the investment decision

Model fit - Within the reasonable range of 3 (more precisely, 3.119), the chi-square divided by degrees of freedom ($\chi 2$ / df) is acceptable. Compared to the suggested characteristics, the actual Goodness of Fit rating (0.918) is superior. The RMR comes out to be 0.028 according to the boundary estimation. Not only does this model have good fit metrics, but it has also received acceptance from academics.

Supply factors have a significant positive impact on the investment decision of Middle income Gold investors. The investment decision also increases by 71.7% as supply factors increase, suggesting a huge impact of supply availability on investment (B=0.717, b=0.905, p=0.000). The strong correlation between supply factors and investment decisions indicates that when making their investment decisions Middle income Gold investors are far more concerned with the price and ease of obtaining it. All in all, it seems clear that supply factors must be taken into account when analyzing the behavior of Middle income Gold investors. Therefore, it is necessary for companies and financial institutions to closely control and adjust the quantity of gold available, in order to attract and keep these investors. Companies aim to meet the needs of Middle income Gold investors and thus elevate their investment funds by guaranteeing a steady and reliable supply of gold. Just as importantly, awareness of the role of supply factors can enable companies to adjust their marketing strategies and product preferences to better serve this particular investor group. Ultimately, to identify the meaning of supply factors, companies can use the special characteristics and habits of Middle income Gold investors to enhance career advancement and prosperity as well.

CONCLUSION

The demand-side factors affecting gold consumption include income levels, days of religious celebration, times of year to marry, inflation, speculation, storing value, international price trends, and better purity and conforming to the BIS standard. Factors relating to the supply of gold: is there gold parity imports, the amount of recycled gold to fill gaps, policies of the government in relation to gold, tax and gold control laws, quality control mechanisms paying for products mainly on time delivery as designed by jeweler; manufacturers, how effectively import agencies in authorized locations sell gold. These levels of both demand and supply influences have considerable impacts on the investment decisions of gold investors, particularly middle-class investors. These factors are key in the overall demand and supply situation of the gold market. Providing gold in parity with requirements ensures that there is a supply of sufficient size to supply demand, although any gaps can be bridged by the recycled gold. Government policies on gold, supply, as well as tax and control laws also affect the market; while the functioning of quality control mechanisms and product varieties are also symbols for different commodities. Secondly, the taste of modern production techniques, and the availability of designers and artisans. They both greatly determine the preferences of gold investors in the middle class.

Scope for Further Research

The current research took a quantitative research design, and future researchers might consider qualitative studies among gold investors. This could help gain a much deeper understanding of their motivations and decision-making processes. For example, qualitative research methods such as interviews and focus groups may be used to dig deeper into the emotional and psychological factors affecting gold investment behavior. This comprehensive approach will provide a more holistic view of the gold market and help investors make better-informed decisions.Also, research can be extended to know the perspective of Gold sellers and how they perceive the motivations and behaviors of gold investors. Understanding the seller's perspective can provide valuable insights into the dynamics of the gold market and help identify potential risks and opportunities. By combining both the perspectives of investors and sellers, researchers can create a more complete picture of the gold market ecosystem and offer valuable recommendations for both parties. This multi-faceted approach will not only contribute to the existing body of knowledge on gold investments but also provide practical implications for investors and sellers in the market.

ABSTRACT

In medical imaging, where noise may obscure critical details, denoising medical images can be crucial to improving image quality. The SWANIFS (Stationary Wavelet Transform with Adaptive Non-Local Means and Intuitionistic Fuzzy Sets)approach is an innovative hybrid denoising technique that effectively eliminates noise while maintaining image detail. The methodology dynamically alters filtering settings based on noise features, resulting in improved efficiency across an extensive variety of noise categories, which includes Gaussian and Salt-and-Pepper noises. The three models have been thoroughly compared: SWT-ANLM (Stationary Wavelet Transform with Adaptive Non-Local Means), ANLM-IFS (Adaptive Non-Local Means with Intuitionistic Fuzzy Sets), SWT-IFS (Stationary Wavelet Transform with Intuitionistic Fuzzy Sets), as well the proposed SWANIFS model.Based on the evaluation results, SWANIFS performs better denoising, lowering noise while maintaining image quality by achieving a higher Peak Signal-to-Noise Ratio (PSNR) and a lower Root Mean Square Error (RMSE). The proposed strategy is adaptable to varied noise distributions, making it an adaptable approach to improve medical images. These findings highlight SWANIFS's potential to significantly improved image quality by allowing for increased efficiency as well as reliability of analysis in medical imaging.

Keywords: Intuitionistic Fuzzy Sets (IFS), Adaptive Non-Local Means (ANLM), Stationary Wavelet Transform (SWT), Noise Reduction.

INTRODUCTION

Medical imaging is necessary for illness diagnosis, therapy planning, and clinical research [1]. Real-world medical images, on the other hand, are commonly influenced by several types of noise, such as Gaussian noise, salt-and-pepper noise, speckle noise, and Rician noise, which are caused by sensor limits, ambient circumstances, and transmission distortions [2]. These noise disturbances severely reduce image clarity, hindering feature extraction, segmentation, and classification. Although classic denoising methods such as Wiener, Gaussian, and median filtering substantially reduce noise, they frequently result in blurring, loss of fine details, and edge distortion. Fuzzy set theory has significance in image processing because it can deal with ambiguity and imprecise conceptions. In order to overcome the challenges of imprecision and uncertainty, wavelet-based transformations and fuzzy set theory have emerged as practical methods for improving medical imaging. Fuzzy logic [3] allows for a more flexible and adaptive approach to noise reduction by assigning degrees of membership, as opposed to traditional denoising algorithms, which treat pixel intensities as absolute values. This is notably beneficial in medical image processing, since anatomical components commonly exhibit gradual intensity changes, making binary categorization impractical. Fuzzy logic-based techniques successfully minimize noise while preserving structural details [4]. Intuitionistic Fuzzy Sets (IFS) are an extension of standard fuzzy sets that improve image processing by including a level of hesitation in addition to membership and non-membership functions. IFS provides a more accurate representation of uncertainty, which makes it particularly useful for medical imaging affected by noise [5]. The hesitation component, which also ensures that critical anatomical traits are kept throughout filtration, allows the system to better handle unclear regions. The proposed SWANIFS technique improves medical image denoising by combining Adaptive Non-Local Means (ANLM), Intuitionistic Fuzzy Sets (IFS), and Stationary Wavelet Transform (SWT). The Stationary Wavelet Transform (SWT) uses shift-invariant multi-resolution analysis to successfully extract noise from key features, retaining picture information. By managing uncertainty through membership, non-membership, and hesitation degrees, IFS improves image quality and ensures more clarity in difficult places. Adaptive Non-local Means (ANLM) filtering reduces noise while preserving texture. Combining these technologies enables SWANIFS to improve adaptive processing, edge retention, and noise reduction. It beats current medical picture preprocessing algorithms by decreasing structural distortion, improving fine anatomical features, and increasing diagnostic precision.

LITERATURE SURVEY

Liu and Zhang [6] proposed a wavelet-based soft-thresholding approach for medical image denoising that incorporates Non-Local Moment Mean (NMM) filtering. The technique isolates distinct frequency components by first employing the wavelet transform to breakdown the noisy image. The noise is then suppressed using NMM filtering, while structural information is retained. By enhancing intensity and minimizing artifacts, this method improves image quality. The experimental results outperform existing denoising algorithms, especially in terms of preserving fine features in CT and MRI images. For denoising MR brain images, Srinivasan and Gurunathan [7] developed the enriched intuitionistic fuzzy adaptive filtering (IFAF) technique. To effectively eliminate various noise types, such as Gaussian and salt-and-pepper noise, the technique combines intuitionistic fuzzy logic with adaptive filtering. It adapts to various noise levels while retaining critical anatomical components. The results show that the signal-to-noise ratio (SNR) and contrast enhancement have been improved than using common filtering procedures. The technique improves image clarity and is ideal for medical diagnostic applications. The authors emphasize its usefulness for automated brain MRI preprocessing. Badawy *et al*. [8] developed a hybrid denoising method for breast ultrasound images that combines Intuitionistic Fuzzy Enhancement and Wavelet Transform. The image is refined using intuitionistic fuzzy logic by keeping important details, while the wavelet decomposition efficiently removes noise from high-frequency image components. By reducing noise-related distortions and enhancing image contrast, this combination increases the accuracy of lesion detection. The experimental validation demonstrates that

diagnostic performance for breast cancer screening has improved significantly. Zhang and Zhou [9] implemented a hybrid wavelet-fuzzy system to reduce noise in medical images. The model isolates noise using wavelet-based multi-resolution analysis, and fuzzy logic improves the filtering process. This method suppresses undesirable noise while preserving important image characteristics like edges and texturing. The approach has been demonstrated on a variety of medical imaging datasets, indicating increased image quality and feature extraction. The study indicates that combining wavelet analysis and fuzzy logic offers superior noise reduction over traditional methods. Kim *et al.* [10] investigated Adaptive Wiener Filtering to reduce noise in CT scans. The technique minimizes over-smoothing effects by constantly modifying filter parameters in response to local noise fluctuations. It efficiently removes Poisson and Gaussian noise while maintaining fine anatomical features, which are essential for precise medical diagnosis. In comparison to traditional Wiener filtering, the evaluation findings reveal that denoised images have better contrast and clarity. The filter's adaptability makes it appropriate for real-time medical imaging applications. Bilateral filtering, a technique that smoothes noise while maintaining edges, has been explored by Xie *et al.* [11] for MRI denoising. Unlike standard filters, bilateral filtering takes into consideration both spatial and intensity information, preserving fine structure in medical images. This technique is especially useful for segmentation tasks since it decreases noise without distorting important characteristics. The technique outperforms Gaussian and median filtering in terms of edge preservation, according to the analysis.

Abdullah *et al.* [12] originated a neutrosophic-based segmentation model for DICOM images, which significantly improves abnormality identification in medical diagnosis. By converting image pixels into truth, indeterminacy, and falsity components, the technique increases the accuracy of segmentation.By using adaptive thresholding, the method maintains important anatomical information while fine-tuning region boundaries. A hybrid denoising technique for MRI and CT images was proposed by Liu and Chen [13] utilizing fuzzy logic and the Curvelet Transform. Fuzzy logic improves noise reduction, while Curvelet Transform maintains edges. The method outperforms wavelet-based algorithms, improving image quality and disease identification. In preprocessing for segmentation and classification, it works especially well. Singh *et al.* [14] used Intuitionistic Fuzzy C-Means (IFCM) clustering and Discrete Cosine Transform (DCT) filtering to segment brain MRI images. While DCT filtering minimizes noise, IFCM guarantees accurate region segmentation. This method boosts segmentation performance in clinical and AI-driven medical imaging by improving feature extraction and classification. Existing denoising techniques, such as wavelet transforms, non-local means, and fuzzy logic, improve medical image quality but struggle to strike an appropriate balance between noise reduction and detail preservation. Existing denoising methods, such as wavelet transforms, non-local means, and fuzzy logic, improve medical image quality but struggle to balance noise reduction with detail preservation. In order to fill this gap, we offer SWANIFS (Stationary Wavelet Transform, Adaptive Non-Local Means, and Intuitionistic Fuzzy Sets), which dynamically adapts to noise modifications while preserving fine details and increasing computational effectiveness. This method offers a strong and flexible foundation for segmenting and denoising medical images in real time.

Image

An image is a collection of pixel data representing grayscale or color intensities. Due to sensor limitations, distribution artifacts, and acquisition conditions, noise is frequently present in medical images. The noise is intentionally introduced into the analysis utilizing traditional mathematical models in order to get a regulated output. Noise's impact can be expressed numerically as:

$i(x) = o(x) + n(x)$

Where,$i(x)$indicatesthe original image,$o(x)$ is the original image and$n(x)$ denotes the noise introduced at pixel x.Figure 1(a)(b)[15] includes both the original and noised images.

Intuitionistic Fuzzy Sets (IFS)

Atanassov's [16] 1986 invention of Intuitionistic Fuzzy Sets (IFS) expands standard fuzzy set theory by introducing another dimension of uncertainty. Every element in the universe is assigned a membership degree in classical fuzzy sets, indicating how much it belongs to a specific set. However, there is frequently hesitancy or ambiguity when deciding on membership values in many real-world situations, particularly in complex and ambiguous contexts. To

address this constraint, IFS has three fundamental parts: a membership function, a non-membership function, and a hesitation margin.

Mathematical Representation

An intuitionistic fuzzy set A in a universe $U$is defined as $A = \{(x, \mu_A(x), v_A(x)) | x \in U\}$
where,

- $\mu_A(x)$ is the membership degree $(0 \leq \mu_A(x) \leq 1)$
- $v_A(x)$ is the non-membership degree $(0 \leq v_A(x) \leq 1)$,
- $\pi_A(x) = 1 - (\mu_A(x) + v_A(x)$is the hesitancy degree.

This level of hesitancy accommodates for doubt or a lack of information about an element's specific membership. There is no uncertainty when the intuitionistic fuzzy set collapses to a conventional fuzzy set when $\mu_A(x) + v_A(x) = 1$, the intuitionistic fuzzy set reduces to a standard fuzzy set, meaning there is no hesitation. When $\mu_A(x) + v_A(x) < 1$, there is a degree of indeterminacy, making IFS particularly useful in dealing with incomplete or imprecise data. With the addition of the hesitation component, IFS is now highly effective in a variety of real-world applications involving uncertainty. It is frequently utilized in areas such as medical image processing, pattern identification, machine learning, making decisions, and systems for expertise. For instance, IFS improves segmentation methods in image processing by offering a more adaptable visualization of pixels categorization, which makes it possible to handle noise and uncertain regions more effectively. Furthermore, by taking expert opinion uncertainty into account, IFS makes it possible to simulate individual judgment more accurately in decision-making situations.When it comes to managing uncertainty, intuitionistic fuzzy sets offer a more thorough and adaptable framework than conventional fuzzy sets. Their capacity to incorporate hesitation makes them ideal for applications requiring specific classification, resulting in more secure and dependable outcomes across a wide range of computational components and experimental fields.

Applying IFS In Wavelet Transform For Noise Filtering

Using an IFS-based function, each pixel in a wavelet-transformed image's approximation sub-band (LL) is assigned membership $\mu_A(x)$and non-membership $v_A(x)$values.
To determine a pixel's degree of belongingness, the membership function $\mu_A(x)$ is computed as:

$$\mu_A(x) = \frac{I(x) - I_{min}}{I_{max} - I_{min}} \quad (1)$$

This is how the non-membership function $v_A(x)$is computed as:

$$v_A(x) = \frac{I_{max} - I(x)}{I_{max} - I_{min}} (2)$$

It specifies the degree to which a pixel does not belong to a specific fuzzy set.
We can derive the hesitation degree $\pi_A(x)$ as follows:

$$\pi_A(x) = 1 - \mu_A(x) + v_A(x) \quad (3)$$

This shows the level of uncertainty in pixels identification.

Stationary Wavelet Transform

SWT, a translation-independent and redundant variation of DWT, is used for noise reduction and visual perfection [17]. This technique is more effective at keeping picture details than DWT since it does not down sample the image. In this work, we use shift/translation invariant SWT to divide a noisy image into approximation and accurate coefficients. SWT on the residual image preserves crucial microscopic aspects of structure in biometric visuals. Because of this property, SWT is extremely beneficial for denoising, feature extraction, and multi-resolution analysis in medical image processing.

Steps for Decomposition

Without down sampling, the SWT adds high-pass and low-passfilters to the signal.
Approximation coefficients (Low-Pass Filter output)

$B_j(m) = \sum_p l_j(p) B_{j-1}(m-p)$ (4)

Detail coefficients (High-Pass Filter output)

$C_j(m) = \sum_p h_j(p) B_{j-1}(m-p)$ (5)

The approximation coefficients at scale j are denoted by B_j(m), while the detail coefficients are denoted by C_j(m) represents the detail coefficients. Low-pass and high-pass filters are denoted by the variables $l_j(p)$ and $h_j(p)$, respectively.

Inverse Stationary Wavelet Transform

The denoised image is reconstructed from its altered coefficients using the Inverse Stationary Wavelet Transform (ISWT), which maintains important image components [18]. In contrast to the conventional DWT, ISWT reduces aliasing effects and improves reconstruction accuracy by eliminating down sampling and maintaining shift-invariance. Through the use of ISWT, the Stationary Wavelet Transform (SWT) denoised approximation and detail coefficients are synthesized back into the spatial domain, preserving fine textures and features while reducing undesired distortion. Medical images are better suited for diagnostic applications because to this reconstruction procedure, which improves their visual quality.

Adaptive Non-Local Means (Anlm) Filtering

Conventional denoising methods frequently fail to strike a compromise between preserving detail and reducing noise, especially in highly textured or medical images [19]. Despite its capacity to reduce noise by averaging identical pixel brightness throughout an image, Non-Local Means (NLM) filtering is not sensitive to local noise level fluctuations. This restriction may result in insufficient noise removal in severely damaged areas or excessive blurring in fine structures.The dynamic weighting method implemented by Adaptive Non-Local Means (ANLM) filtering adapts according to the local noise variance in order to overcome these obstacles. Instead of using a constant smoothing parameter, ANLM incorporates an adaptive factor λ to modify the influence of surrounding pixels, ensuring appropriate response to varying noise levels in the image. This flexibility improves edge preservation and noise reduction, increasing its effectiveness in circumstances where quality of structure is essential.

Mathematical Representation

According to the standard NLM filter, the denoised pixel I(x) is estimated to be:

$I(x) = \sum_{y \in \Omega} w(x,y)$ (6)

Where:

The similarity weight between pixels x and y, denoted by w(x,y), is calculated using a Gaussian-weighted Euclidean distance.

The search window is indicated by the symbol Ω.

The intensity value of the adjacent pixel is denoted by I(x).

In contrast to conventional NLM, the ANLM weight function adjusts based on the local noise characteristics, which is expressed as:

$w_\lambda(x,y) = \frac{1}{Z(x)} \exp\left(-\frac{||I(P_x) - I(P_y)||^2}{h_\lambda(x)^2}\right)$ (7)

$I(P_x)$ and $I(P_y)$ → Represent intensity patches around pixels x and y.

$h_\lambda(x)$ → Adaptive filtering parameter that changes based on local noise levels.

$Z(x)$ → Normalization factor to ensure sum of weights equals 1.

By incorporating the parameter λ, the filter's performance improves dramatically, especially in keeping small features and tolerating fluctuating noise levels.

Proposed Approach: Swanifs Filtering

The proposed hybrid denoising approach, SWANIFS, which integrates the Stationary Wavelet Transform (SWT), Intuitionistic Fuzzy Sets (IFS), and Adaptive Non-Local Means (ANLM) Filtering, improves medical images by efficiently reducing noise while maintaining essential structural information.The comparison analysis compares

various combinations of these methodologies, including SWT-ANLM, SWT-IFS, ANLM-IFS, and the integrated SWANIFS strategy. The detailed steps are as follows.

Step 1: Image decomposition using SWT

The stationary wavelet transform (SWT) is used to dissect the input noisy medical image. The process of decomposition produces detail coefficients (high-frequency components) and approximation coefficients (low-frequency components). The primary image structure is preserved in the approximation sub band, whereas noise and fine image textures are present in the detail sub bands.

Step 2: Processing the Intuitionistic Fuzzy Set (IFS).

To improve contrast and maintain edges, the approximation coefficients are processed with an Intuitionistic fuzzy set (IFS). Pixels are classified into intensity levels using membership and non-membership functions. To control pixel intensity and improve image clarity, a fuzzy enhancement transformation is used.

Step 3: Detail Coefficient Filtering using ANLM

The detail coefficients produced from SWT decomposition are subjected to adaptive non-local means (ANLM) filtering. By employing a weighted averaging technique, ANLM determines pixel similarity while preserving significant image attributes. To improve image quality, processed coefficients are recombined.

Step 4: Image Reconstruction Using Inverse SWT (ISWT)

To generate the final image, the denoised approximation and detail coefficients are reconstructed using Inverse SWT (ISWT). This method minimizes noise while preserving structural details.

Step 5: Generate the output.

The final denoised image is obtained, which is clearer and more suitable to medical analysis. The flow chart in Figure 2 depicts the work flow.

Parameters For Evaluation

The PSNR and MSEare used in this work to assess the filter's efficacy.

THE PEAK SIGNAL-TO-NOISE RATIO (PSNR)

In image processing, the Peak Signal-to-Noise Ratio (PSNR) is a frequently used statistic for comparing a processed or reconstructed image to the original reference image in order to assess its quality[20]. The ratio of the original and processed images Mean Squared Error (MSE) to the peak signal intensity is how it is expressed. Better quality is implied by a greater PSNR result, which shows a closer similarity between the two images. PSNR is calculated using the following formula:

$$\text{PSNR} = 10.log_{10}\left(\frac{MAX^2}{MSE}\right) \quad (8)$$

In other words, MAX stands for the maximum potential pixel value in the image. Mean Squared Error (MSE) of original and processed images. An image with a greater PSNR value is of higher quality.

THE ROOT MEAN SQUARED ERROR (RMSE)

A popular metric for measuring the discrepancy between processed or expected outcomes and actual or reference values is Root Mean Squared Error (RMSE), which is used in image processing and many other domains [21]. This tool is very useful for evaluating image accuracy and fidelity after reconstruction or filtering. To compute RMSE, take the square root of the mean of the squared differences between pixel values in original and processed images[20]. RMSE is calculated using the following mathematical formula:

$$\text{RMSE} = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(I_o(i) - I_p(i))^2} \quad (9)$$

where N is the total number of pixels andI_o(i) and I_p(i) stand for the pixel intensities of the original and processed images, respectively.

Analysis And Findings

The image is processed using a denoising framework that uses Intuitionistic Fuzzy Set based Adaptive Non-Local Means (IFS-ANLM) filtering and Stationary Wavelet Transform (SWT). Before denoising, the medical image is initially affected with Gaussian and Salt-and-Pepper noise. The denoising procedure is carried out with MATLAB, and metrics such as the Root Mean Square Error (RMSE) and Peak Signal-to-Noise Ratio (PSNR) are used to assess how well various filtering strategies perform. In terms of preserving image quality, SWANIFS (SWT + IFS+ANLM) performs better than conventional filtering methods, as shown by the PSNR (Peak Signal-to-Noise Ratio) values for Gaussian noise in Table 1. The RMSE (Root Mean Square Error) values are also shown in Table 2, where lower RMSE scores support the suggested method's better denoising capabilities. Figure 3 demonstrates denoised images for Gaussian noiseat each step of the proposed technique. The corresponding graphical representation is shown in Figures 4 and 5. The Salt and Pepper noise RMSE (Root Mean Square Error) values are shown in Table 3, emphasizing SWANIFS better noise suppression capabilities. The consistently decreased RMSE values demonstrate the effectiveness of the suggested strategy in preserving important image structures while successfully reducing noise. Table 3 and Table 4 is represented graphically in Figures 7 and 8, which provide a comparison of the RMSE values. Furthermore, Figure 6 displays denoised images for Salt and Pepper noise, demonstrating the efficiency of the suggested denoising method. These results demonstrate that the SWANIFS approach achieves higher PSNR and lower RMSE compared toexisting approaches. The integration of IFS and ANLM after SWT decomposition is a novel strategy that effectively balances noise reduction and edge preservation, improving the clarity of medical images for better diagnostic accuracy.

CONCLUSION

The main objective of this work is to create analyze a hybrid denoising technique for CT image preprocessing by comparing SWANIFS' performance against the results of SWT-IFS, ANLM-IFS, and SWT-ANLM across different levels of noise. Noise reduction filters are applied to CT images with different types of noise, and their performance had been assessed using PSNR and RMSE. These data show that the proposed SWANIFS method outperforms conventional methods for noise suppression while keeping critical image information. It has the potential to enhance medical diagnostics because to its ability to endure Gaussian and salt-and-pepper noise.The proposed method can be extended to various imaging methods, upgrading their ability to adapt to various levels of noise. It can also be used in more sophisticated applications for image processing, such as classification and segmentation.

ABSTRACT

Liquid Chromatography–Mass Spectrometry (LC–MS) is an advanced analytical technique that integrates the separation efficiency of liquid chromatography (LC) with the detection and identification strength of mass spectrometry (MS). It serves as a vital tool across various fields including pharmaceuticals, biotechnology, environmental analysis, and clinical research, enabling both qualitative and quantitative analysis of complex mixtures. The evolution of bioanalytical methods has significantly enhanced pharmaceutical research, particularly in the accurate quantification of drugs and their metabolites. This progress has led to the development of combined analytical instruments designed for precise bioanalysis. Among them, LC–MS stands out as a key technique that merges the physical separation of LC with the mass-based detection of MS, allowing for sensitive and specific measurement of analytes.This review provides an overview of LC–MS, covering its introduction, working principle, Pros & cons, and its diverse applications in scientific and industrial research.

Keywords Bio analysis, liquid chromatography, Mass spectrometry, metabolites, clinical research.

INTRODUCTION

Liquid chromatography

Liquid Chromatography (LC) is a powerful separation technique used to isolate individual components within a mixture. The process is based on mass transfer between the mobile phase (a liquid solvent, usually polar) and the stationary phase (a solid, often non-polar) contained within a column. Separation occurs due to differences in the interactions of sample molecules with these two phases, allowing compounds to elute at different times. LC can be employed for both analytical purposes (to identify and quantify components) and preparative applications (to purify larger quantities of a substance). This method utilizes sophisticated instrumentation operating under high pressure, which is why the terms LC and HPLC (High-Performance Liquid Chromatography) are often used interchangeably. The widespread popularity of LC stems from its high sensitivity, quantitative accuracy, ease of automation, and its ability to analyze non-volatile or thermally unstable compounds. It is also highly adaptable for diverse substances across industrial, pharmaceutical, and scientific applications [1].

Traditionally, LC columns were 50 to 500 cm long and packed with solid particles coated with an adsorbed liquid, forming the stationary phase. To maintain adequate flow rates through such columns, the particle size of the packing material was typically kept larger than 150–200 μm.

Mass spectrometry

A mass spectrometer is an instrument that produces ions and separates them according to their mass to charge ration (m/z).

Mass spectrometric analysis involves the following steps

Atomization

Conversion of a substances fraction of the atoms formed in step1 to a stream of ions.

Separating the ions formed in step 2 on the basis of their mass to charge ratio [m/z].

M=mass of the number of ion in atomic mass unit. Z=number of fundamental charges. [2]

Normally mass spectroscopy is used in three principal ways

To measure relative molecular masses [molecular weights] with very high accuracy.

To detect with in a molecule the places at which it prefers to fragment.

As a method for identifying analytes by comparison of their other mass spectra.

Liquid Chromatography- Mass Spectrometry

LC-MS is an analytical technique that couples high resolution chromatographic separation with sensitive and specific mass spectrum detection.

Combination of LC-MS is an important development in the history of chromatography.

Mass spectroscopy in LC-MS helps to determine the elemental composition and structural elucidation of a sample.

It is powerful technique used for many applications which has very high sensitivity and selectivity.

It is commonly used in the pharmacokinetic studies of pharmaceuticals and it is the most frequently in field of bioanalysis.

LC-MS also play a role in pharmacognosy especially in the field of molecular pharmacognosy when it comes to the ingredients in the different aspects of phenotypic cloning. [3]

Pros of LC-MS -

It is one of the most powerful analytical tools for organic compound analysis.

The key advantages of LC/MS Method over HPLC Methods includes -

1. Selectivity – co-eluting peaks can be isolated by mass selectivity and are not constrained by

chromatographic resolution.

2. Peak assignment – A chemical finger print for the compound of interest generated ensuring correct peak assignment in the presence of complex matrices.
3. Molecular weight information – confirmation and identification of known and unknown compounds.
4. Structural information – controlled fragmentation enables structural elucidation.
5. Rapid method development – provides easy identification of elucidated analytes without retention time validation.
6. Sample matrix adaptability - decreases sample preparation time.
7. Quantitation – quantitative and qualitative data can be obtained easily with limited instrument optimisation. [4]

CONS

1. Expensive
2. Not portable
3. Requires an experienced technician
4. Moderate through put. [5]

Bio Analytical Techniques

Some techniques normally utilised in bio analytical studies -

1. Hyphenated techniques

LC-MS (Liquid chromatography –mass spectrometry)
GC –MS (Gas chromatography – mass spectrometry)
CE –MS (Capillary electrophoresis – mass spectrometry)

2. Chromatographic strategies

HPLC (High performance liquid chromatography)
Gas activity. [6]

Principle Involved In LC-MS -

- Typical LC-MS system is the combination of HPLC with MS using Interface (Ionisation source). The sample is separated by LC and the separated sample species are sprayed into atmospheric pressure ion source, where they ate converted into ions in the gas phase.
- The mass analyser is then used to sort ions according to their mass to charge ratio and detector counts the ions emerging from the mass analyser and may also amplify the signal generated from each ion.
- As a result mass spectrum (a plot of the ion signal as a function of mass to charge ratio) is created, which is used to determine the elemental nature of a sample, the masses of the particle and also molecules, and to elucidate the chemical structures of molecules.
- Two key components in this process are the ion source, which generates the ion and mass analyser, which sorts the ions.
- Several different types of ions sources are commonly used for LC/MS. [7]

Components of LC-MS -

A major difference between traditional HPLC and Chromatography used in the LC-MS is that the scales is much smaller ,

- with respect to the internal diameter of the column and with respect to flow rate since it scales as the square of diameter.
- For a long time, 1mm columns were typical for LC-MS work.
- 300µm and even 75µm capillary columns have become more prevalent.
- At the low end of these column diameters the flow rates approach 100 ml/min and are generally used with nanospray sources.

Mobile Phase -
The mobile phase is the solvent that moves the solutes throughout the column.

General requirements
1. Low cost, UV transparency, high purity.
2. Low viscosity, low toxicity, non flammability.
3. Non – Corrosive to LC-MS system components.

Column type
- Specialised mode.
- The di –functional (or) Tri functional silanes creates bonded groups with two (or) three attachment points leading to the stationary phase with higher stability in low (or) higher P^H.
- Most widely used columns for LC-MS are -

1. Fast LC column

The use of short column (15-50 mm)

2. Micro LC column

The use of large column (20 -150mm)

Sample Preparation
- Sample preparation generally consists of concentrating the analyte and removing the compounds that can cause back ground ion (or) suppress ionisation.
- Examples of sample preparation include -

1. On – column concentration to increase the analytes concentration.
2. Desalting to reduce the sodium and potassium adduct formation that commonly occurs in electroscopy.
3. Filtration to separate a low molecular weight drug from proteins in plasma, milk (or) tissues.

Solvent Pumping and Solvent Injection -
- The common types of pumping are -

1. **Direct gas – pressure system** -

Which is inexpensive and reliable. However, changing solvent is difficult.

2. **Syringe pumps -**

Which is inexpensive and reliable, very accurate and precise and can have a large capacity.

3. **Pneumatic intensifier -**

Which operates under constant pressure, any blockage can cause a pressure drop and consequently pulses.

4. **Reciprocating pumps -**

Which are economical solutions that provide a constant flow and high pressure, but can cause pulsing.
The sample injector should work with in very small volumes and withstand high pressure of solvent. Most devices use sample injection works valves instead of direct injection valves because of the former have superior characteristics. It is possible to inject the samples into the valves loop automatically with an auto – sampler (or) manually using a micro syringe. [8-9]

ION Sources -
Electro spray ionisation (ESI)
Atmospheric pressure chemical ionisation (APCI) Atmospheric pressure photo ionisation (APPI)

Electro spray ionisation (ESI)
It is a process of ionisation followed by evaporation which occurs in three basic steps -

1. Nebulisation and charging -

The HPLC effluent is pumped through a nebulising needle which is at ground potential. The

potential difference between the needle and electrode produces a strong electric field. This field charges the surface of liquid and forms spray of charged droplets. There is a concentric flow of gas which assists in nebulisation process.

2. Desolvation -

The charged droplets are attracted towards the capillary sampling orifice. There is counter flow of heated nitrogen drying gas which shrinks the droplets and carries away the uncharged material.

3. Ionisation -

As the droplets shrinks, they approach to a point where the electrostatic forces exceeds the cohesive forces. This process continues until the analyte ions pass through the capillary sampling orifice into the low pressure region of ion source and the mass analyser.

ATMOSPHERIC PRESSURE CHEMICAL IONISATION (APCI) -

APCI, A process of evaporation followed by ionisation, is complementary to electro spray ionisation.

1. Nebulisation and desolvation -

APCI nebulisation is similar to that in API- ES. However, APCI nebulisation occurs in a hot (typically 250º-400ºc) vaporizer chamber. This heat rapidly evaporates helium spray droplets, resulting in gas – phase HPLC solvent and analyte molecules.

2. Ionisation -

The gas – phase solvent molecules are ionised by the discharge from a coronora needle. In APCI, there is a charge transfer from the ionized solvent reagent ions to analyte molecules in the way that is similar to chemical ionisation in GC-MS. These analyte ions then are transported through the ion optics to the filter and detector.

Atmospheric Pressure Photo Ionisation (APPI) -

APPI for LC-MS is a relatively new techniques. As in APCI, a vaporiser converts the LC eluent to the gas phase. A discharge lamp generates photons in a narrow range of ionisation energies. The range of energies is carefully chosen to ionize as many analytes molecules as possible while minimising the ionisation of solvent molecules. The resulting ion passes through a capillary sampling orifice into the mass analyser. [10-11]

MASS ANALYSERS -

The mass analyser used for LC-MS are of four types

1. Quadra pole
2. Time of flight
3. Ion trap
4. Fourier transform – ion-cyclotron resonance (FT-ICR/FT-MS)

QUADRAPOLE -

A Quadra pole mass analyser consists of four parallel rods arranged in a square. The analyte ions are directed down the centre of the square. Voltages applied to the rods generated electromagnetic fields. These fields determine which mass to charge ratio of ions can pass through a filter at a given time. Quadra poles tend to be the simplest and least expensive mass analyzers.

Quadra pole mass analysers can operates in two modes -

1.Scanning (scan) mode 2.Selected ion monitoring (SIM) mode

In scan mode, the mass analyzer monitors a range of mass to charge ratios. In SIM mode,

the mass analyser monitors only a few mass – to-charge ratios.

SIM mode significantly more expensive than scan mode but provides information about fewer ions. Scan mode is typically used for qualitative analyses (or) for quantitation when all the analytes masses are not known in advance. SIM mode is used for quantitation and monitoring of target compounds.

Time of Flight - (TOF)

In a TOF mass analyser, a uniform electromagnetic force is applied at the same time, causing them to accelerate down a flight tube. Lighter ions travel faster and arrive at the detector first, so the mass to charge ratios of ions are determined by arrival times. TOF analyser has a wide mass range and can be very accurate in their mass measurements.

ION Trap -

An ion trap mass analyser consists of circular ring electrodes plus two ends caps that together form a chamber. Ions entering the chamber are trapped there by EMF. Another field can be applied to selectively eject ions from the trap. Ions traps have the advantages of being able to perform multiple stages of mass spectrometry without additional analysers.

Fourier-Transform Cyclotron Resonance (FT-ICR)

An FT-ICR mass analyser also called as (FT-MS) is another type of circular orbits by powerful electrical and magnetic fields. The ions generate a time dependent current. This current is converted by Fourier transform in to orbital frequencies of the ions which correspond to their mass to charge ratios. [12]

APPLICATIONS

Pharmaceutical Analysis

- LC-MS is extensively used for drug identification, impurity profiling, and metabolite detection during drug development. [13]
- It supports characterization of degradation products, helps in ensuring drug purity and stability under various conditions. [14]
- Metabolism studies in vitro (e.g. liver microsomes) or in vivo (plasma/urine sampling) often rely on LC-MS to detect and quantify drug metabolites. [15]
- It is also used for pharmacokinetic and pharmacodynamic monitoring, e.g. therapeutic drug monitoring of immunosuppressants and anticancer agents.[16]

Bioanalysis

- LC-MS enables quantitative measurement of drugs, drug-metabolites, biomarkers in biological fluids (blood, plasma, urine).
- For example, in pharmacokinetic studies (PK) it allows measurement of concentrations over time with high sensitivity—helpful especially where levels are low or where matrix is complex.[17]
- It can also be used in clinical diagnostics, e.g. monitoring biomarkers in patient samples.

Proteomics & Metabolomics

- In proteomics, LC-MS / LC-MS-MS (tandem MS) is used to identify, sequence and quantify proteins in complex mixtures by first digesting proteins into peptides, then separating by LC and analyzing by MS.18
- It helps in biomarker discovery comparing peptide / protein expression between healthy vs disease states, identifying post-translational modifications (PTMs), etc. [19]
- In metabolomics, LC-MS is used to profile small-molecule metabolites in biological samples, enabling detection of hundreds to thousands of compounds, comparison across sample groups, and discovery of metabolite changes associated with disease, treatment, or condition.[20]

Environmental Testing

- LC-MS enables the detection and quantification of pollutants, pesticides, herbicides, and emerging contaminants in environmental matrices (water, soil, sludge).[21]

- Emerging contaminants (e.g. pharmaceuticals and personal care products in water) can be traced even at very low concentrations (e.g. nanogram per litre) using LC-MS-MS, often without need for complicated derivatization.[22]
- It also supports environmental risk assessment by quantifying the levels of toxic or regulated chemicals across samples.[23]

Food Industry

- In food safety/quality, LC-MS is used to detect food contaminants, such as pesticide residues, mycotoxins, and adulterants in food products.
- It is also used for nutritional profiling or to analyze additives / preservatives.
- For regulatory compliance, food industries use validated LC-MS or LC-MS/MS methods to ensure that levels of harmful substances are below permissible limits.[24]

CONCLUSION

Liquid Chromatography–Mass Spectrometry (LC–MS) is an advanced analytical technique that integrates high-resolution chromatographic separation with highly sensitive and specific mass spectrometric detection. It serves as a powerful tool for in vitro analysis of drug metabolites, new drug discovery, screening of phytochemical constituents, and identification of impurities and degradation products in pharmaceutical formulations. Ongoing advancements in LC–MS technology have further enhanced its capability for the efficient separation, detection, and identification of analyte ions, making it indispensable in modern analytical and pharmaceutical research.

ABSTRACT

A disease is considered an emerging infectious disease (EID) if it has recently appeared in a community or if its frequency or geographic prevalence is rapidly increasing. They are caused by parasites, fungi, viruses, and bacteria, and often result from complex interactions among people, animals, and the environment. The Zika virus, Nipah virus, COVID-19, Ebola, and multidrug-resistant TB are among the prominent EIDs. The global spread of EIDs is further facilitated by unsanitary environments, rapid global mobility, international trade, and climate change. EIDs seriously threaten global health because they overwhelm healthcare systems, upend economies, and foster widespread stigma and dread. A clear example of how quickly a new infectious agent may impact global health, the economy, and social order is the COVID-19 pandemic. Strong monitoring, public education, and prompt scientific action are all necessary for EID control. The creation of vaccines is crucial because platforms such as mRNA, viral vectors, protein subunits, and inactivated vaccines offer preventative measures. Agencies such as the

Centers for Disease Control and Prevention (CDC) are leading the EID response through outbreak investigation, strengthening health infrastructure, and working in partnership globally. Prevention and management of EIDs need to be addressed by a holistic approach that involves international cooperation, investments in health systems, research into novel treatments and vaccines, and the application of the one health approach, acknowledging the interlinks between human, animal, and environmental health. Preemptive readiness and cooperation are the needs of the time to minimize the effects of emerging infectious challenges in the present and future. This review discusses the types of EIDs, sources of EIDs, factors of EIDs, global impact, transmission, vaccination and prevention and control of EIDs.

Keywords: Emerging Infectious Diseases, Center for Disease Control and Prevention, Infectious Disease, Antimicrobial Resistance, Remerging Diseases.

INTRODUCTION

An emerging infectious disease (EID's) is any infectious disease that has newly emerged in a population or long-time present but with a quick rise among the population.Emerging infectious diseases (EIDs) are defined as new, re-emerging, or drug-resistant infections that continuously persist in testing public health systems around the globe. EID's were predominantly caused by pathogens such as bacteria, viruses, fungi, or parasites [1]. These instances highlight the unforeseen nature of pathogens and the imperative for anticipatory measures. Complex interactions between people, animals, as well as the environment are the source of EIDs. While antimicrobial resistance (AMR) complicates treatment, global travel, deforestation, urbanization, and climate change all contribute to its quick spread. EIDs are not only health problems but also threats to international security and development, as seen by the economic and social disruption caused by pandemics like the COVID-19 pandemic [2]. Emerging infectious diseases (EIDs) are illnesses that have just surfaced or are rapidly spreading throughout a community, or that have shown a dramatic increase in frequency or geographic distribution. They include either recently identified pathogens or previously identified microorganisms that have evolved to become more resistant or pathogenic. Examples include COVID-19, Zika, SARS, Ebola, and HIV/AIDS.

EIDs can spread by several routes, including direct contact with infected people or animals, respiratory droplets, mosquito-borne insects, contaminated food and water, and, in rare cases, blood transfusions. The majority of these infections are zoonotic, meaning they started in animals before spreading to people [3]. EIDs have a profound impact on cultures, economy, and health all around the world. They put strain on healthcare systems and cause illness and deaths. The COVID-19 pandemic showed how quickly a novel infection may disrupt daily life, lead to a decline in the economy, and generate societal problems, including stigma and disinformation. Vulnerable populations are often impacted by these, especially in low-income communities [4]. In order to identify, track, and manage EIDs, the Centers for Disease Control and Prevention (CDC) is essential. It supports outbreak response teams, conducts surveillance, creates infection control standards, and works globally to improve readiness. . Combating emerging infectious diseases needs international cooperation, investment in the health system, and ongoing research for the next generation to save human life [5]. The 21st century has seen repeated outbreaks in the form of SARS (2003), H1N1 influenza (2009), Ebola (2014–2016), Zika (2015–2016), and COVID-19 (2019–ongoing).

Types of emerging infectious diseases:

The EID's can be classified in several ways, including by how and when they appear, their causes, and their patterns of spread or resistance. Here are the main types:

1. **Newly Emerging Infectious Diseases:** Diseases not previously described in humans.
2. **Re-emerging Infectious Diseases:** Known diseases that are increasing again in incidence, geographic range, or severity, or have become resistant to treatments.

3. **Deliberately Emerging Infectious Diseases:** Diseases intentionally created or spread by humans, usually for bioterrorism.
4. **Accidentally Emerging Infectious Diseases:** Diseases unintentionally created or spread by human actions, such as contamination or laboratory accidents.
5. **Emerging Due to Antimicrobial Resistance:** Previously known diseases that have reemerged because of new resistance to one or more medicines.
6. **Old Diseases Newly Classified as Infectious:** Diseases not initially recognized as infections, but later shown to have an infectious cause.
7. **New Strains or Variants of Known Pathogens:** Mutations in existing pathogens leading to more infectious or dangerous strains.
8. **Diseases Emerging in New Geographic Areas or Hosts:** Recognized infections appearing in new places, species, or populations—often due to environmental or societal changes [6,7,8].

Emerging Infectious Diseases Occur in Humans:

There are mainly three categories that occur in human beings. They are:

1. Viral Emerging Infectious Diseases
2. Bacterial Emerging Infectious Diseases
3. Fungi &parasites Emerging infectious Diseases

Viral Emerging Infectious Diseases:

Viral emerging infectious Diseases are illnesses caused by viruses. The diseases tend to come from animal reservoirs (zoonotic sources) and may leap to humans because of habitat loss, wildlife trade, or close contact between humans and animals. The majority of viral emerging diseases are transmitted by RNA viruses, which are prone to rapid mutation and therefore more versatile and more difficult to contain. They can be transmitted via multiple routes, such as air, body fluids, or insect vectors, and tend to have no effective treatments or vaccines at the time of emergence [5].

Bacterial emerging infectious disease:

Emerging bacterial diseases are bacterial infections among humans. They can emerge as a result of several factors, including antibiotic resistance, unsanitary conditions, international travel, and environmental change. One of the most significant issues with bacterial EIDs is the emergence of drug-resistant pathogens, including multidrug-resistant tuberculosis (MDR-TB) and extensively drug-resistant typhoid (XDR-typhoid), which complicate treatment and pose a risk of mass outbreaks. Certain bacterial infections, including cholera and plague, are reviving owing to breakdowns in public health interventions or shifting climate patterns. These diseases spread extremely fast within communities with compromised healthcare systems or unsanitary living conditions. The need for innovative treatment approaches, improved infrastructure for cleanliness, and efficient disease surveillance systems to curb the spread and consequences of emerging bacterial infections makes them a significant public health concern[24].

Parasite & Fungal Emerging Infectious Diseases:

Newly emerging infectious diseases brought on by fungi or parasites. They frequently appear as a result of environmental upheaval, climate change, international travel, and weakened immune systems in vulnerable groups. Similar to antibiotic-resistant malaria or leishmaniasis, parasitic EIDs are typically spread by insect vectors like sandflies or mosquitoes and are more difficult to treat because of their resistance to standard drugs. Because they spread quickly and are resilient to many antifungal medications, fungal EIDs, such as Candida auris, are a major issue in hospitals. The increasing adoption of immunosuppressive therapies, organ transplants, and invasive medical techniques has also raised the risk of invasive fungal infections. The "emerging diseases" underscore the importance of improved diagnostics, therapy, and infection control measures to guard public health [30].

Sources of Emerging Infectious Diseases:

The EID's mainly originate from the following key sources [34,35].

Animal reservoirs: The majority of the EID's originated from the animals. Its nearly estimated 60%-80% cases were caused to the human beings from animals. The animal reservoir is also known as zoonoses. This zoonotic spillover can occur directly or through vectors like mosquitoes and ticks.

Microbial adaptation: Pathogens, such as influenza viruses, can mutate or undergo genetic shifts, increasing their ability to infect humans or evade immunity.

Environmental and ecological changes: Deforestation, farmland expansion, climate change, and other forms of environmental disruption bring humans and animals into closer contact, increasing opportunities for new disease emergence.

Globalization and travel: Increased international travel and trade facilitate the rapid spread of infectious agents across regions where they were previously unknown or rare.

Changes in human behaviors: Urbanization, increased population density, and risky practices like bushmeat hunting have amplified human contact with animal reservoirs and vectors.

Healthcare-associated settings: Spread of new pathogens (e.g., drug-resistant organisms or emerging fungi like *Candida auris*) is often amplified within hospitals among vulnerable populations.

Breakdown in public health systems and deliberate biological threats: Lapses in disease surveillance, infrastructure, or intentional release of biological agents can contribute to disease emergence and re-emergence [3,35].

Factors of the Emerging Infectious Diseases:

Emerging infectious diseases result from intricate interactions among pathogens, hosts, and their environment. Knowledge about these factors is paramount to anticipating and averting outbreaks. The following are the major drivers of EIDs, examined in depth [36].

Zoonotic Spillover and Animal Reservoirs:

The majority of EIDs have animal origins before leaping into humans via zoonotic transmission. SARS-CoV-2 (presumably bats), Ebola (fruit bats), and avian influenza (wild birds) are examples of pathogens that exist in animal reservoirs prior to viral spillover into human populations. Wildlife trade, consumption of bushmeat, and agricultural expansion are some of the factors that enhance human-animal interactions, thereby increasing cross-species transmission risk. Deforestation and habitat loss further bring wildlife into contact with human settlements, hence giving rise to new viral spillover opportunities.

Ecological Disruption and Climate Change:

Climate change changes the geographic range of disease vectors and hosts, increasing the area where pathogens such as malaria, dengue, and Lyme disease circulate. Warmer temperatures allow mosquitoes, ticks, and other vectors to flourish in previously uninhabitable areas, and extreme weather patterns (droughts, floods) alter ecosystems and expose more humans to zoonotic diseases. Warming of oceans also influences marine pathogens, leading to seafood-borne disease. These changes in ecology provide ideal conditions for emerging new pathogens and facilitating their spread [37].

Globalization and Expanded Travel:

Global travel and global commerce speed the transmission of contagious illnesses, and pathogens can travel across borders in hours. The speed of global transmission of COVID-19, SARS, and mpox illustrates how globally interconnected today's societies are. Air transport, migration, and commodity supply chains allow illness to reach new populations before containment can be initiated. Urbanization, with highly concentrated urban populations, also encourages outbreaks by raising the rate of person-to-person transmission.

Antimicrobial Resistance (AMR):
Excessive use and inappropriate use of antibiotics in humans, animals, and agriculture have resulted in drug-resistant bacteria, including MRSA and multidrug-resistant tuberculosis. AMR makes infection treatment more challenging, converting once-controlled diseases into potentially lethal conditions. Poor antibiotic stewardship and hospital-acquired infections in low-resource environments fuel the crisis and make bacterial EIDs more difficult to contain [38].

Human Behavioral and Societal Factors:
Human behaviors, such as vaccine hesitancy, hygiene, and unsafe health practices, drive disease emergence. Anti-vaccination campaigns have caused the resurgence of polio and measles in a few areas. Poor healthcare infrastructure, access to unclean water, and irresponsible disposal of waste expose people to infection. Cultural beliefs (such as traditional burial ceremonies for Ebola patients) may drive amplification of outbreaks as well.

Pathogen Evolution and Adaptation:
Viruses and bacteria are constantly evolving to evade immunity and transmit more effectively. RNA viruses such as influenza and SARS-CoV-2 occur more frequently in genetic mutations and produce new variants. Other pathogens also evolve in new hosts and have greater pandemic potential. Laboratory accidents or bioterrorism, although unusual, might release highly virulent or engineered strains.

Weakened Public Health Systems:
Weakened healthcare facilities in low-income nations find it difficult to detect early, monitor, and respond to outbreaks. Delay in reporting, absence of diagnostic equipment, and inadequate finances hamper swift containment. Disparities in vaccine availability across the world continue to fuel outbreaks, such as COVID-19 and cholera in resource-poor environments. Improved health infrastructure and collaboration across borders are necessary to avert these threats [39].

Global Impact of Emerging Infectious Diseases on Humans
EIDs are a serious worldwide threat to human health. The recent COVID-19 pandemic demonstrates how rapidly a new virus can spread across the globe, overburdening the health infrastructure and severely impacting daily life. In addition to causing illness and death, EIDs often cause substantial financial damage and societal unrest. Their devastating effects are especially likely to affect developing nations with inadequate healthcare infrastructure.

The global impacts include
Health Burden: EIDs like COVID-19, the Ebola virus, Zika, and the avian influenza affect millions of people. These infections have the potential to cause death or long-term health issues.

Economic Loss: The world economy is negatively impacted by restrictions on travel, shutdowns, and a reduced labor pool.

Psychological Impact: The stigma, anxiety, and dread associated with illness epidemics hurt mental health.
Global Preparedness: EIDs brought attention to the need for improved disease surveillance programs, worldwide cooperation, and research led by organizations like the WHO and the CDC [40].

Threat of Emerging Infectious Diseases (EIDs) to Human Life
Because of their unpredictable origin, rapid spread, and high potential for causing serious illness or death, emerging infectious diseases (EIDs) pose a major and growing threat to human life. Due to urbanization, globalization, and increased human-animal interaction, illnesses can spread quickly among communities and may arise suddenly, usually through reservoirs of wildlife or environmental changes [16].

Health Impact

EIDs have the potential to cause severe disease and high mortality, particularly in those caused by new pathogens for which no treatment or vaccine is available. SARS, COVID-19, and Ebola are some such examples. Populations such as the elderly, newborns, and immune compromised are especially vulnerable.

Overburdened Healthcare Systems

When there are outbreaks, clinics and hospitals tend to be flooded with a sudden influx of patients. It overextends medical services, leads to shortages in necessary drugs and equipment, and affects the treatment of other non-infectious diseases.

Economic Consequences

Massive epidemics have the potential to destabilize economies by impacting labor productivity, closing industries, and slowing world trade. The COVID-19 pandemic is a prime example of how an individual disease has caused world economic recessions and unemployment.

Social and Psychological Stress

EIDs bring widespread panic, fear, stigma, and mental distress. Lockdowns for prolonged periods, isolation, and uncertainty over disease spread lead to depression, anxiety, and other psychological disorders.

Risk to Global Security

Unchecked outbreaks can travel across borders and become pandemics, posing a risk to world health security. They have the potential to destabilize countries by impacting workforce health, security forces, and vital services.

Developmental Reverse

In poor nations, EIDs are capable of undoing decades of advances in healthcare, education, and economic development. Children can lose access to education, and poverty can increase as a result of disease and healthcare expenses [47].

Modes of Transmission to Humans

There are a lot of ways that are transmitted to humans from other animals or the environment. Some of them are [46].

Direct Transmission

This takes place when the causative agents are transferred directly from an infected person to a healthy individual through bodily contact. Such contact may be in the form of touching, kissing, or sexual intercourse. HIV/AIDS, herpes, and Ebola are some examples of infections that are transmitted through direct exposure to bodily fluids or open sores.

Indirect Transmission

In this category, diseases are spread through contaminated surfaces or objects (fomites). Touching contaminated personal belongings, medical devices, or doorknobs can, for instance, transmit norovirus and the common cold in poorly hygienic environments.

Droplet Transmission

Diseases can be spread by large respiratory droplets that are released when an infected individual cough, sneezes, or talks. Such droplets move a short distance and infect others by entering through the eyes, nose, or mouth. COVID-19, influenza, and whooping cough are often transmitted this way [6].

Airborne Transmission

Contrary to droplet transmission, airborne transmission has small particles (aerosols) that are suspended in the air for extended durations and travel further. These particles can cause infection when inhaled. Tuberculosis, measles, and chickenpox are prime examples of airborne transmission [6] [7].

Vector-Borne Transmission

Here, the infections are spread through insect vectors like mosquitoes, ticks, or fleas. These vectors transfer the pathogens from a host to another host by biting them. For instance, malaria, dengue, Zika virus, and Lyme disease are all spread by insects.

Zoonotic Transmission

Zoonoses are illnesses that are transmitted from animals to humans, either directly (by bites or scratches) or indirectly (through vectors). Examples of such zoonotic diseases are rabies, Ebola, and MERS, which are caused by animals such as bats, dogs, and camels.

Foodborne and Waterborne Transmission

This type includes the oral ingestion of food or water containing pathogens. Pathogens can infect the digestive system and lead to diseases such as cholera, typhoid fever, and hepatitis A. Inadequate sanitation and hygiene are the main causes of these outbreaks.

Vertical (Maternal) Transmission

Also referred to as mother-to-child transmission, this is when infections are transmitted from an expectant mother to her child during pregnancy, birth, or lactation. All of the diseases, such as HIV, hepatitis B, and Zika virus, can be spread this way and potentially impact the development or survival of the newborn [48,49,50].

Fig.3: Emerging Viral Disease Transmission Mechanisms Using Typical Pathogens (Both dengue fever and zika fever are spread by mosquitoes and can spread vertically, from mother to fetus. The main way that influenza, COVID-19 (SARS-CoV-2), and MERS spread is by respiratory droplets, which are frequently produced from zoonotic reservoirs. Mpox (monkeypox) and the Ebola virus are spread by direct contact with infected people or bodily fluids. The picture also emphasizes how human hosts, vectors, and reservoirs contribute to the spread of illness.)

Types of Vaccines For Eids

EIDs are characterized by special challenges that necessitate novel vaccine strategies. The following are the primary types of vaccines employed or in development for EIDs, their mechanism, strengths, and weaknesses.

mRNA Vaccines: Quick and Flexible

mRNA vaccines, including those that have been created for COVID-19, utilize genetic material to tell cells to create viral proteins, which elicit an immune response. The vaccines are very responsive to updating for new strains. They do need ultra-cold storage and potentially frequent booster shots because immunity wanes. Scientists are working on mRNA vaccines for other EIDs such as Zika and Nipah virus. This vaccine also causes side effects like injection site reactions, fatigue, and allergic reactions.

Viral Vector Vaccines: Balanced Efficacy and Stability

Viral vector vaccines, such asthe COVID-19 vaccine and the Ebola vaccine, utilize harmless viruses to introduce genetic material from the target disease. They produce robust immune responses and are more stable than mRNA vaccines, but prior immunity to the vector (e.g., adenovirus) can diminish effectiveness. Future uses may involve HIV and Marburg virus vaccines [10]. This also causes the potential side effects, risk of vector shedding.

Protein Subunit Vaccines: Safe but Slower to Develop

Protein subunit vaccines, are made up of purified viral proteins and adjuvants that boost immunity. They are extremely safe and stable but may necessitate several doses and take longer to manufacture. Such vaccines are in the works for universal flu vaccines and Nipah virus protection. This vaccine may have weak immune response & multiple doses are required [51].

Inactivated Vaccines: Traditional but Reliable

Inactivated vaccinesutilize killed virus particles to cause immunity. They are immunologically safe for immune-compromised patients but need boosters since the immune responses are weaker. Production further requires high-containment facilities to avoid contamination. This vaccine may not provide long lasting immunity compared to live vaccines.

Live-Attenuated Vaccines: Strong and Long-Lasting

Live-attenuated vaccines, employ weakened live viruses to trigger strong, long-term immunity. Yet, they are inappropriate for immune-compromised persons and remain at a low risk of returning to virulence. Such vaccines fight diseases such as yellow fever and measles [10]. This vaccine can cause mild disease in immune-compromised individuals and it is not suitable for people with weakened immune system [52].

DNA Vaccines: Future Promise

DNA vaccines encoded plasmid DNA of viral proteins. They are easy to make and stable at room temperature but have shown weaker immune responses in humans compared with animals. Research work is in progress to enhance their efficacy concerning diseases such as Zika and HIV. This vaccine may not always produce a strong immune response. It can be difficult to deliver DNA into cells effectively.

VLP Vaccines with Safety and Efficacy

VLP vaccines, such as those for HPV and hepatitis B, are virus-like structures without genetic content, which are non-infectious but extremely immunogenic. Their complicated production is costly, but they are good candidates for Ebola and norovirus vaccines. These vaccines may not produce a strong or consistent immune response.

Nanoparticle Vaccines: Next-Generation Solutions

Nanoparticle vaccines, utilize small particles to improve antigen delivery and immune responses. They promise potential for universal flu and HIV vaccines but need more research to establish long-term safety and effectiveness. The potential for nanoparticles to cause toxicity or adverse reactions [53].

Selecting the Best Vaccine for EIDs

The ideal vaccine form varies by speed of development, worldwide access, and persistence of immunity. mRNA and viral vector vaccines lead the way in quick deployment, with protein subunit and inactivated vaccines providing greater access. Live-attenuated and VLP vaccines yield long-term protection but require more stringent safety issues [54].

Future Directions in EID Vaccination

The vaccine world is being revolutionized by a number of groundbreaking strategies. Nasal or oral mucosal vaccines target the creation of sterilizing immunity at infection sites - various inhaled COVID-19 boosters are in advanced clinical trials. Self-amplifying RNA vaccines have the potential to deliver the same protection at 1/10th the dose of today's mRNA vaccines. Computational design of vaccines with AI neural networks has now designed new immunogen for RSV and influenza that are superior to natural antigens in animal models. Thermostable formulations by silk protein matrices or sugar glass preservation can completely do away with cold chain needs. Every platform has its own strengths to contribute towards the complicated task of emerging pathogens. Future prospects most probably reside in combining in a strategic manner - DNA/mRNA for initial quick response and

protein nanoparticle booster, or mucosal prime followed by systemic boosts. As the COVID-19 experience has shown, diversified vaccine platforms will need to be sustained through research funding during inter-paned [55].

Centers for Disease Control and Prevention for EIDS

The Centers for Disease Control and Prevention (CDC) is the United States' major public health agency in the combat of emerging infectious diseases (EIDs). These diseases—newly discovered, previously unrecognized, or newly re-emerging after having decreased—are serious threats to global health security. The CDC is critical to the detection, monitoring, and reaction to such threats using a mix of sophisticated surveillance networks, rapid outbreak investigations, scientific inquiry, and global collaboration. Using leading-edge technologies such as genomic sequencing and artificial intelligence, the CDC monitors the evolution of pathogens in real-time, which makes it possible to issue early warnings of likely pandemics [56].

During outbreaks, the CDC activates its Emergency Operations Center (EOC) to coordinate containment efforts and deploys rapid-response teams using the Epidemic Intelligence Service (EIS). As seen throughout the COVID-19 pandemic, Ebola outbreak, and MPOX epidemic, it also develops diagnostic tests, treatment protocols, and immunization schedules. By working with organizations like the World Health Organization (WHO) and providing funds for disease surveillance networks in high-risk regions, the CDC continues its efforts to develop global health infrastructure in addition to emergency response. The CDC also offers key public health information to healthcare providers, policymakers, and the public, providing evidence-based methods to reduce transmission [57,58].

By its One Health strategy, the CDC is studying the interconnection of human, animal, and environmental health, understanding that most emerging diseases (like avian influenza or Lyme disease) are caused by zoonotic spillover. By the investment in pandemic preparation, monitoring of antimicrobial resistance, and vaccine development, the CDC continues to be ahead of preventing the next infectious disease disaster. Its efforts not only save American lives but also build global capacity to protect against future outbreaks [59].

DISCUSSION

The sudden emergence and re-emergence of infectious diseases are the result of intricate interplay between human activity, environmental change, and pathogen evolution. With more than 70% of EIDs being zoonotic in nature, rising contact between people and animals—through forest loss, wildlife trade, and habitat encroachment—has radically increased spillover risk. Urbanization, international travel, and climate change increasingly promote the easy spread of these pathogens. Pandemics such as COVID-19 have demonstrated how susceptible even the most advanced countries can be when faced with a new virus. EIDs are not only classified by the manner in which they emerge—newly emerging, re-emerging, or as a result of resistance—but also by the cause: viral, bacterial, parasitic, or fungal. Each requires certain control measures. For example, viral EIDs such as Nipah or Zika call for vector management and vaccine induction, while bacterial EIDs call for better sanitation and antimicrobial stewardship.

In the battle against EIDs, new vaccine platforms provide quick and responsive solutions. The emergence of mRNA and viral vector vaccines amidst the COVID-19 pandemic reflects science's ability to respond quickly to international health emergencies. The classic vaccines and new platforms such as virus-like particles (VLPs) and nanoparticles are meanwhile broadening the arsenal to prevent EIDs. However, immunization is insufficient on its own. International collaboration, public education, early diagnosis, and robust surveillance systems are crucial. Through programs like One Health, which integrate perspectives on environmental, animal, and human health, organizations like the CDC play a crucial role. During health emergencies, the spread of false information has also become a major concern. The development of vaccines is accelerated and effective distribution is ensured by pharmaceutical businesses, biotechnology companies, and logistical suppliers. These new issues highlight the necessity of addressing EIDs with a comprehensive, interdisciplinary, and internationally coordinated strategy.

CONCLUSION

In the twenty-first century, emerging infectious diseases (EIDs) remain one of the biggest public health concerns. Their unpredictable nature, along with increasingly significant risk factors like climate change, globalization, and antibiotic resistance, emphasizes the importance of careful planning and preparedness for any response. Successfully combating EIDs requires a multidisciplinary approach that combines education, international collaboration, public health infrastructure, and scientific innovation. We have a strong foundation to meet future problems because to the efforts of agencies like the CDC, advancements in vaccine technology, and disease surveillance. Life and global health security depend on sustained investment, cross-sector cooperation, and awareness. Vaccination is insufficient on its own. International collaboration, public education, early diagnosis, and robust surveillance systems are crucial. Through programs like One Health, which integrate perspectives on environmental, animal, and human health, organizations like the CDC play a vital role.

Table 1: Classification of Emerging Infectious Diseases with Key Examples

Type	**Key Examples**
Newly emerging	COVID-19, MERS, HIV, Ebola [9,10]
Re-emerging	Drug-resistant TB, measles, MRSA [11,12]
Deliberately emerging	Anthrax (bioterrorism), smallpox [12]
Accidentally emerging	Vaccine-derived poliovirus [9,12]
Antimicrobial resistance-driven	MDR-TB, drug-resistant malaria, MRSA [12,13]
Old diseases newly classified	Peptic ulcer (*Helicobacter pylori*) [9]
New strains/variants of pathogens	*E. coli* O157:H7, novel influenza strains [10,14]
Emerging in new regions/hosts	West Nile in the USA, Zika in the Americas [10,12]

Table 2: Overview of Emerging Infectious Diseases with their Causative Agents, Modes of Transmission

Disease	Causative Agent	Transmission
COVID-19	SARS-CoV-2	Airborne, droplets, contact [9,12]
SARS	SARS-CoV	Droplets, contact [9,12]
MERS	MERS-CoV	Camels to humans, droplets [12, 15]
Ebola Virus Disease	Ebola virus	Body fluids, contact [12, 16]
Zika Virus Infection	Zika virus	Mosquito bites (Aedes spp.), sexual [12, 17]
Nipah Virus	Nipah virus	Bats, pigs, human-to-human [18]
Avian Influenza (H5N1, H7N9)	Influenza viruses	Contact with infected birds [12, 16]
Swine Flu (H1N1)	Influenza A virus	Airborne, droplets [9, 12]
Dengue Fever	Dengue virus	Mosquito bites (Aedes spp.) [12, 19]
Chikungunya	Chikungunya virus	Mosquito bites [12, 20]
Monkeypox (Mpox)	Orthopox virus	Contact with lesions, droplets [12, 16]
West Nile Virus	West Nile virus	Mosquito bites [16, 21]
Crimean-Congo Hemorrhagic Fever	CCHF virus	Tick bites, body fluids [12, 22]
Japanese Encephalitis	JEV (Flavivirus)	Mosquito bites (Culex spp.) [23]

Table 3: Overview of Emerging Infectious Diseases with their Causative Agents, Modes of Transmission

Disease	Causative Agent	Transmission
Multidrug-Resistant TB (MDR-TB)	*Mycobacterium tuberculosis*	Airborne [12]
Extensively Drug-Resistant Typhoid	*Salmonella Typhi*	Contaminated food/water [25]
Anthrax (reemerging)	*Bacillus anthracis*	Spores via skin, inhalation [26]
Plague	*Yersinia pestis*	Fleas, rodents [27]
Cholera (reemerging)	*Vibrio cholerae*	Contaminated water [28]
MRSA	*Staphylococcus aureus* (resistant strain)	Contact, healthcare-associated [29]

Table 4: Overview of Emerging Infectious Diseases with their Causative Agents, Modes of Transmission

Disease	Causative Agent	Transmission
Drug-resistant Malaria	*Plasmodium* spp. (resistant strains)	Mosquito bites (*Anopheles* spp.) [31]
Leishmaniasis (reemerging)	*Leishmania* spp.	Sandfly bites [32]
Candidiasis (drug-resistant)	*Candida auris*	Hospital-acquired, contact [33]

Table 5: Over the Past Three Decades, People Worldwide Have Suffered From Eids

Disease	Period	Estimated Global Cases	Estimated Deaths	Origin Area
COVID-19 (SARS-CoV-2)	2019–present	770 million+	7 million+	Wuhan, China [12]
H1N1 Influenza (Swine Flu)	2009–2010	1.4 billion	284,000	Mexico & Southern USA [41]
Ebola Virus Disease	2014–2016, 2018–2020	34,000+	14,000	Central & West Africa [12,16]
Zika Virus	2015–2016	1 million+ (confirmed)	Few deaths	Uganda, Brazil [42]

ABSTRACT

The rise of more antimicrobial resistance among existing drugs makes the treatment for the infectious diseases challenging. Space leads to looking for new medicines or therapies with the same benefits. Sinusitis is one among the diseases related to microorganisms from bacteria and viruses to fungi. The Siddha system of medicine mentioned about 4448 diseases and about plenty of Medicines, treatment options including both internal and external for the diseases. This ancient medicine needs to undergo scientific studies to explore its potential. One such Siddha formulation *Peenisa Chooranam* is indicated for *Peenisangal, Nasi naatram and Nasi raththam,* which can be correlated with the symptoms of Sinusitis. This study aimed to evaluate the antimicrobial activity of *PeenisaChooranam*against infectious pathogens using agar well diffusion method. The formulation was tested against gram positive organisms *Staphylococcus aureus, Bacillus cereus*, gram negative organisms*Escherichia coli, Klebsiella pneumonia*and fungi *Candida albicans* using agar well diffusion method comparing with commercially available drugs. *Peenisa Chooranam* exhibited significant antimicrobial activity against gram-positive, gram-negative organisms and fungi than commercial drugs especially shown high zone of inhibition against *Escherchia coli* particularly at 150 mg/ml concentration. It shows less on *Bacillus cereus*. The findings suggest that the Siddha formulation *Peenisa Chooranam* can be a potential treatment option against infections. Still, Further studies are required to explore its clinical applications.

Keywords: *Antimicrobial activity, Sinusitis, Antibiotic resistance, Staphylococcus aureus, Escherchia coli.*

INTRODUCTION

Both acute and chronic sinusitis are frequent diagnoses in healthcare settings. They are caused by inflammation of the mucous lining, which inhibits mucociliary function of the nose and para nasal sinuses [1]. Blocked sinuses may become contaminated with viruses or bacteria [2]. Common symptoms of rhinosinusitis include nasal congestion, obstruction, or discharge; facial pain or pressure, as well as loss of smell, may also be present [3]. It occurs as a reaction to virus, bacteria or allergic reactions. Thus, the treatment aims at eradicating bacterial pathogens, draining secretions and reducing inflammation. Headache may occur when sinus inflammation stimulates trigeminal nerve [2]. The causative microorganisms include *Rhinovirus, influenza virus,* and *parainfluenza virus* among viruses and among common pathogenic bacteria, it also includes *Streptococcus pneumoniae, Haemophilus influenzae, Moraxella catarrhalis,* and *Streptococcus pyogenes* with acute sinusitis and *Staphylococcus aureus* and anaerobic bacteria with chronic sinusitis [4]. Siddha medicine *PeenisaChooranam* (PC) with its ingredients *Chukku, Milagu, Thippili, Chenkathari, Kodiveli, Kandangkathiri, Sangam ver, Karunjeeragam* and *Seeragam*, indicated for *Peenisangal, Nasi naatram and Nasi raththam.* The Siddha condition *Peenisam*and its associated symptoms can be correlated with Sinusitis. Because of emerging antibiotic resistance, new drug with more potency and antimicrobial action may be welcoming to treat the diseases. With that note, this study deals with antimicrobial activity of Siddha medicine *PeenisaChooranam* (PC) against infectious pathogens using Agar well diffusion method, comparing with commercially available drugs.

MATERIALS AND METHODS

Sample preparation

Following appropriate drug authentication by botanists, purification, and preparation in accordance with the literature, the study medication *PeenisaChooranam* (PC) was prepared, filtered by *vasthrakayam*and stored in the airtightcontainer [5,6,7].

Study place: The study was conducted at Drug Standardisation Research Unit (DTL Approved Laboratory), Regional Research Institute of Unani Medicine, Chennai.

Microbial load determination

The microbiological quality of herbal medicines, including identification and isolation of pathogenic microbes, was studied in accordance with WHO guidelines (2007) and Siddha Pharmacopoeia (2016) [9,10,11,12]. The studies were performed to figure out the number of isolated bacteria and fungi that could develop aerobically in 1 gram of sample. The samples were thoroughly mixed with water to uniformly mix them. A sample weighing one gram was added to nine millilitres of peptone broth. Serial dilutions were carried out to attain suitable concentration. Every microbiological analysis was done three times. Serial dilutions were prepared. The pour-plate method was used to determine viability on Casein soya bean digest agar for bacterial counts and Sabouraud dextrose agar for fungus identification. Following the manufacturer's instructions, all dehydrated medium was prepared, seeded, and incubated for 24 to 48 hours at 37 °C for bacterial screening and for 48 to 72 hours at 25 °C for fungal screening. At the end of the incubation period, the average number of colonies was multiplied by the dilution factor to get the number of colony-forming units per gramme (CFU/g).

Identification of Bacteria

For bacterial isolation and identification, the samples were diluted in water or Tween 80, according to the solubility, and homogenized by vigorously mixing. The 1-mL aliquots were cultivated at the appropriate temperature and time after transferring to 9 mL of peptone broth. All microbial analyses were carried out in triplicate. Culture media such as EMB agar, MacConkey agar, Deoxycholate citrate agar, Cetrimide agar, and Mannitol salt agar were utilized for investigating Escherichia coli, Salmonella spp., Pseudomonas aeruginosa, and Staphylococcus aureus, respectively. Pathogenic bacterial isolates were initially identified by colony morphology, Gram staining, and biochemical tests (oxidase, gas, and catalase production) at the end of the incubation period.

Antimicrobial study

Chemicals and glassware

Glasswares made up of Borosil glass were used throughout the study. Growth media, glassware and other accessories were used after sterilization in an autoclave at 121°C at 15 lbs/sq. inch pressure for 15 min.

Sterilization

The testing microbiology laboratory was sterilized by fumigation with formaldehyde and potassium permanganate for 24 hour every month. The inoculum hood was cleaned with 95% ethanol and exposed to UV light for 20 minutes before every use. The digital weighing balance was also cleaned with 95% ethanol and surgical gloves were used during the experiment for maintaining aseptic condition.

Collection of Test microorganism

To evaluate the microbial studies, few cultures were procured from Clinical Laboratory in and around Chennai. Staphylococcus aureus (ATCC-29213), Bacillus cereus (Clinical Cochin University) (Gram positive), Escherichia coli (ATCC-25922), Klebsiella pneumonia (ATCC-700603) (Gram negative) and Candida albicans (Clinical Cochin University) were the organisms used.

Medium Preparation

A lag phase uniform suspension of all the organisms listed above were prepared by inoculating a loop full of each culture in 10 ml of nutrient broth, incubated at 37°C for about 6 to 8 hours. 38 g of the media (M-H Agar) was suspended in 1000 ml of distilled water. Boiled to dissolve the medium completely and sterilized by autoclaving at 121°C for 15 minutes. Suspend 65 g of the powder (SDA) in 1000 ml of distilled or deionized water. Mix well. Heat to boil shaking frequently until completely dissolved. Sterilize in autoclave at 121°C for 15 minutes.

Sample preparation

10 g of *Peenisa Chooranam* were dissolved in 50 mL of hydroalcohol (1:1) and the sample was kept in a shaking incubator for 24 to 48 hours. The solution was filtered through Whatman No. 1 filter paper once the formulation was completely soluble. The filtered extract was evaporated in a hot air oven at 40℃ for one day. And the final extract was weighed and dissolved using the same solvent at 50, 100 & 150 mg/mL concentration used for the further assay.

Antimicrobial activity of formulation PC

The *Peenisa Chooranam* (PC) was tested for their antimicrobial activity using the Agar well diffusion method. All the cultures used for the study were obtained from Clinical Laboratory in and around Chennai. The Medium was prepared using Mueller Hinton Agar and Sabouraud dextrose agar, which was subsequently autoclaved. The autoclaved media was mixed thoroughly while still hot and then added to 100 mm Petri plates (25-30 ml/plate). Then, the bacterial strains that had been cultured for 24 hours were transferred to the medium. The wells, which were 10 mm in diameter and made from agar, were filled with 100 µl of diluted formulation at different concentrations (50,100 & 150 mg/ml). The commercially available drug Amp: Ampicillin 10mcg; Nx: Norfloxacin10mcg; Ap: Amphotericin 20mcg was used as control. The plates were then incubated at 37 °C for bacteria and 30 °C for fungus for 12 to 24 hours. Following a 24-hour incubation period, the test analyses the efficacy of the sample PC based on the zone of inhibition (mm in dm)of the organism. All of the experiments were conducted twice [8].

RESULT

Table 2: Microbial load determination of *PeenisaChooranam*
Table 3: Antimicrobial activity of *PeenisaChooranam*

DISCUSSION

The microbial load determination of the medicine *Peenisa Chooranam* (PC) show that the total bacterial count is $1x10^4$CFU/g and total fungal count is Less than 1 CFU/g, and it is absent of Enterobacteriaceae, *Escherichia coli, Salmonella Spp*, *Staphylococcus aureus and Pseudomonas aeruginosa,* which are all within the permissible limits. The sample's measured CFU/g was compared with WHO standards. In accordance with WHO criteria for aerobic bacteria, samples exhibiting bacterial growth over 10^5 CFU in 1 g of herbal medicine were considered inadequate or unsatisfactory. This satisfying microbial load determination reveals that the medicine is safe, and it is in good quality. Regarding antimicrobial activity, the sample was analysed with *Staphylococcus aureus, Bacillus cereus, Escherichia coli, Klebsiella pneumonia* and *Candida albicansat* different concentrations (50,100 & 150 mg/ml) using Mueller Hinton Agar and Sabouraud dextrose agar by agar well diffusion method. The standard used was Ampicillin 10mcg; Nx: Norfloxacin10mcg; Ap: Amphotericin 20mcg. The higher the zone of inhibition, the test sample will be more effective. At 50 mg/ml concentration of PC, highest zone of inhibition was observed in *Escherichia coli*(18 mm), lowest in *Klebsiella pneumonia* (19 mm) and similar zone of inhibition observed in both *Staphylococcus aureus*and *Candida albicans*(17mm) whereas none seen in *Bacillus cereus*. At 100 mg/ml concentration of PC, highest zone of inhibition was observed in Klebsiella *pneumonia*and *Escherichia col*(20mm); the little less zone of inhibition 19mm was observed in *Staphylococcus aureus* and *Candida albicans.* The lowest among all was observed in *Bacillus cereus* (11mm). At 150 mg/ml concentration, the highest 25mm was observed in *Escherichia coli*. 23mm was observed in *Candida albicans*, 22mm was observed in *Staphylococcus aureus*and *Klebsiella pneumonia.* 16mm was observed in *Bacillus cereus*.

Staphylococcus aureus, major human pathogen (gram positive bacteria) which causes infections that are common both in community-acquired as well as hospital-acquired settings. The treatment also challenging because of its strains including MRSA [13]. The sample *PeenisaChooranam* (PC) shows 22mm zone of inhibition in *Staphylococcus aureus* at 150 mg/ml concentration whereas the standard Ampicillin 10mcg shows 17mm zone of inhibition. *Bacillus cereus* is a toxin-producing facultatively anaerobic gram-positive bacterium. This quickly multiplying pathogen when ingested can cause gastrointestinal illness include diarrheal illness without significant upper intestinal symptoms and a predominantly upper GI syndrome with nausea and vomiting but without diarrhea, associated with exoenzyme production [14]. The study sample PC shows 16mm zone of inhibition in *Bacillus cereus* at 150mg/ml concnetration whereas the standard Ampicillin 10mcg shows no zone of inhibition. *Klebsiella pneumonia*is a gram-negative encapsulated bacteria associated with pneumonia that can lead to infection and antibiotic resistance [15]. The sample PC shows 22mm zone of inhibition in *Klebsiella pneumonia* whereas the standard Norfloxacin10mcg shows 15mm.

Escherichia coli is a gram-negative bacillus that can lead to diarrheal illnesses, including traveler'sdiarrhea and dysentery, uncomplicated cystitis, pneumonia, and bacteremia. It is a common cause of nosocomial infections, including catheter-associated UTI's and ventilator-associated pneumonia. *E. coli* strains result in spectrum of disease from mild, self-limited gastroenteritis to renal failure and septic shock [16]. The sample PC shows 25mm zone of inhibition in the organism *Escherichia coli* at 150 mg/ml whereas the standard Norfloxacin10mcg shows 18mm zone of inhibition. *Candida albicans* is a common commensal fungus that colonizes the oropharyngeal cavity, gastrointestinal and vaginal tract, and skin. Its virulence traitslead to candidiasis. Also, candidosis is an early sign of immunodeficiency in HIV infection patients [17]. The sample *PeenisaChooranam* (PC) shows 23mm zone of inhibition in the organism *Candida albicans* at 150 mg/ml concentration whereas the standard Amphotericin 20mcg shows 13mm zone of inhibition. *Peenisa Chooranam* (PC) exhibits significant antimicrobial effect in zone of inhibition against all standards, especially at 150 mg/ml concentration.

A well-known Siddha medicine *Thirikadugu Chooranam* consists of ingredients *Chukku, Milagu, Thippili,* is being used for respiratory ailments. *Chukku, Milagu, Thippili*all the three are herbal ingredients of *PeenisaChooranam* along with other ingredients as well. Microbial activity of *ThirikaduguChooranam* was already studied which also exhibited good antimicrobial activity [18]. Also, complex of many herbal ingredients in poly-herbal formulation, adds strength to the cumulative action. This also justifies the present study.

CONCLUSION

From this study, it is concluded that the Siddha Medicine *PeenisaChooranam* (PC) show very good antimicrobial action through zone of inhibition against infectious pathogen including gram-positive, gram-negative organism and fungi. Further, the bio-active chemicals must be isolated and characterized by various advanced studies and instruments to create novel antimicrobial medications from Siddha system of Medicine.

ABSTRACT

This study examines the effect of economic growth and renewable energy consumption on environmental degradation in India during the period 1990–2020. Using the Autoregressive Distributed Lag (ARDL) model and Granger causality tests, the analysis evaluates both short- and long-term relationships among key variables, including economic growth, renewable energy use, oil prices, foreign direct investment (FDI), and population. The short-term results reveal that renewable energy consumption and oil prices exert a positive and significant impact on environmental degradation, while population growth shows a negative association. Conversely, long-term findings indicate that renewable energy consumption and economic growth significantly reduce environmental degradation, whereas FDI, oil prices, and population growth exacerbate it. Granger causality analysis highlights unidirectional causal links between economic growth and environmental degradation, renewable energy and environmental degradation, as well as between FDI, environmental degradation, and economic growth. These findings underscore the complexity of India's energy–growth–environment nexus, suggesting that while renewable energy offers long-term environmental benefits, inefficiencies and transitional challenges may undermine its short-run effectiveness. The study recommends targeted policy measures to enhance renewable energy efficiency, align FDI with green technologies, and ensure sustainable economic growth in India.

Keywords: Environmental degradation, renewable energy consumption, economic growth, ARDL model, Granger causality, India, sustainable development.

INTRODUCTION

The relationship between economic growth, renewable energy consumption, and environmental degradation has emerged as a critical concern for developing economies like India. Rapid industrialization, urbanization, and population growth have intensified the demand for energy, often resulting in increased greenhouse gas emissions and ecological imbalances (Shahbaz *et al*., 2013). While economic growth contributes to higher income levels, improved living standards, and technological advancement, it is frequently associated with environmental costs such as deforestation, air pollution, and rising carbon emissions (Grossman and Krueger, 1995). In this context, renewable energy has been positioned as a sustainable alternative to fossil fuels, with the potential to mitigate environmental degradation while supporting long-term growth (Apergis and Payne, 2010). India, being one of the world's fastest-growing economies, has made significant strides in expanding its renewable energy sector, particularly in solar and wind power, to balance growth with environmental sustainability (IRENA, 2020). However, the dynamics between renewable energy use, economic growth, and environmental quality remain complex, requiring empirical investigation. This study seeks to analyze the effect of economic growth and renewable energy consumption on environmental degradation in India, providing insights into whether cleaner energy adoption aligns with sustainable development goals.

Objectives

To examine the impact of renewable energy consumption and economic growth on environmental degradation in India during the period 1990–2020, using ARDL and Granger causality approaches.

Statements of the problem

India's rapid economic growth over the past three decades has been accompanied by a significant rise in energy demand, largely met through fossil fuels, resulting in severe environmental degradation (Pachauri and Spreng, 2011). While renewable energy sources are increasingly promoted as a sustainable alternative, their role in reducing ecological damage remains debated. Empirical studies show that economic expansion often exacerbates carbon emissions and resource depletion, raising concerns about the trade-off between growth and environmental sustainability (Shahbaz *et al*., 2013). Moreover, despite India's commitments to global climate agreements, the nation continues to face challenges in balancing industrial development, population growth, and ecological preservation (IEA, 2020). This creates a pressing need to investigate how renewable energy consumption interacts with economic growth to influence environmental outcomes in India. Understanding this nexus is essential for designing policies that foster sustainable development without compromising environmental quality.

Scope and significance of the study

This study focuses on examining the impact of economic growth and renewable energy consumption on environmental degradation in India between 1990 and 2020. By applying econometric approaches, it captures both short-term and long-term dynamics, providing evidence on whether renewable energy adoption mitigates ecological harm while sustaining growth. The scope extends to analyzing causal linkages between economic, demographic, and energy-related factors influencing environmental quality. The significance lies in its contribution to policy formulation for achieving sustainable development goals. With India committed to expanding renewable energy capacity and reducing carbon intensity, insights from this study can guide strategies that balance economic expansion with environmental preservation (Bhattacharya *et al*., 2016; IRENA, 2020). It also enriches empirical literature on the energy-growth-environment nexus in emerging economies.

Overview of Reviewed Literature and Research Gap

The relationship between economic growth, renewable energy consumption, and environmental degradation has been widely examined in global and regional contexts. (Grossman and Krueger, 1995) pioneered the discussion through the Environmental Kuznets Curve (EKC) hypothesis, suggesting that environmental degradation initially worsens with economic growth but eventually declines after a certain income threshold. However, this framework has been critiqued for its limited applicability to developing countries, where growth often remains energy-intensive. (Sarkar and Mathavan, 2025) analyze India's agricultural energy use from 1990–2024 using time-series methods. The study links energy consumption with productivity, explores renewable integration, regional disparities, and policy initiatives, highlighting key challenges and opportunities for sustainable energy. Findings are supported by tables, graphs, and sector-specific visuals. (Apergis and Payne, 2010) examined OECD nations and discovered a long-term balance between growth and the use of renewable energy, underscoring clean energy's ability to lessen environmental damage. Yet, their findings may not fully extend to emerging economies like India, where structural energy dependency differs significantly. Similarly, (Shahbaz *et al*. 2013) investigated Pakistan and confirmed the EKC hypothesis, showing economic growth's mixed effects on emissions, but emphasized the importance of renewable adoption for sustainability. (Bhattacharya *et al*. 2016) extended the debate to the top 38 renewable energy-consuming nations, concluding that renewable energy positively influences growth while mitigating emissions. Nevertheless, country-specific dynamics, particularly in South Asia, remain underexplored. (Sarkar and Mathavan, 2024) examine India's energy–growth nexus (2005–2022) using OLS regression and Granger causality. Results show bidirectional reinforcement: higher energy use drives growth, while growth boosts demand. The study urges efficiency improvements, renewable investments, and equitable access, underscoring sustainable energy policies for India's long-term development goals. (IRENA, 2020) further emphasized the global decline in renewable energy costs, strengthening the case for policy-driven clean energy expansion, though it did not specifically address India's environmental degradation nexus. From this review, it is evident that while extensive work exists globally, research focusing specifically on India's renewable energy–growth–environment relationship is limited. Most studies are either cross-country analyses or based on other developing economies, leaving a gap in understanding India's unique structural, demographic, and policy context. This study fills that gap by empirically examining the Indian case from 1990–2020 using ARDL and Granger causality techniques.

MATERIALS AND METHODS

This study investigates the impact of renewable energy consumption (REC) and economic growth (EG) on environmental degradation (ED) in India over the period 1990–2020. The research methodology integrates both time series econometric techniques and causality analysis to capture short- and long-term relationships among the variables.

Data Collection

Annual data for India from 1990 to 2020 were collected for the following variables: environmental degradation (proxied by CO_2 emissions), economic growth (GDP per capita), renewable energy consumption (REC in Mtoe or percentage of total energy), population (POP), foreign direct investment (FDI), and oil price (OP). Sources include the World Bank, International Energy Agency, and government statistical databases.

Stationarity Test

To avoid spurious regression results, the stationarity of each variable was tested using the Augmented Dickey-Fuller (ADF) test. Variables are integrated at either order 0, I(0), or order 1, I(1). The ADF test equation is given by

$$\Delta Yt = \alpha + \beta t + \gamma Yt - 1 + \Sigma(\delta i \Delta Yt - i) + \varepsilon t - 1$$

Where:

ΔYt = first difference of variable Y

α = constant term

t = time trend
p = lag length
εt = error term

ARDL (Autoregressive Distributed Lag) Model
The ARDL bounds testing approach was applied to explore both short-term and long-term relationships among the variables, as it is suitable for a mixture of I(0) and I(1) variables. The general ARDL model is expressed as:

$$\Delta EDt = \alpha + \Sigma(\beta i \Delta EDt - i) + \Sigma(\theta i \Delta EGt - i) + \Sigma(\varphi i \Delta RECt - i) + \Sigma(\psi i Xt - i) + \lambda 1 EDt - 1 + \lambda 2 EGt - 1 + \lambda 3 RECt - 1 + \lambda 4 Xt - 1 + \varepsilon t - 2$$

Where:
EDt = environmental degradation
EGt = economic growth
RECt = renewable energy consumption
Xt = control variables (POP, FDI, OP)
Δ = first difference operator
λ1, λ2, λ3, λ4 capture long-term coefficients
Short-term dynamics are represented by βi, θi, φi, ψi

Granger Causality Test
To identify the direction of causality between variables, the pairwise Granger causality test was conducted using:

$$Yt = \alpha + \Sigma(\beta i Yt - i) + \Sigma(\gamma i Xt - i) + \varepsilon t - 3$$

Where X is said to Granger-cause Y if past values of X significantly improve the prediction of Y.

Model Diagnostics
Standard diagnostic tests were conducted to ensure model reliability, including serial correlation, heteroskedasticity, and stability tests (CUSUM and CUSUMSQ).

Interpretation
Short-term results: Immediate impact of REC, EG, POP, FDI, and OP on environmental degradation.
Long-term results: Persistent effects of these variables on ED over time.
Causality results: Direction of influence among variables to inform policy implications.
This methodology ensures a comprehensive analysis of the energy-growth-environment nexus in India and provides robust evidence for policy formulation.

RESULTS AND DISCUSSIONS

Table 1 indicates the descriptive statistics highlight key characteristics of the variables over 1990–2020. Environmental degradation (ED) averaged 1,120 $MtCO_2$, reflecting India's rising emissions due to industrialization. Economic growth (EG) showed an average GDP per capita of USD 1,540, with a wide spread (450), signaling gradual but uneven growth. Renewable energy consumption (REC) averaged 45 Mtoe, showing slow adoption compared to fossil fuels. Population grew steadily, averaging 840 million, while FDI inflows (USD 2.1 billion) and oil price volatility (USD 40 average) illustrate the influence of global markets on India's economy and environment. Line Graph Descriptive Statistics of Variables (1990–2020) (Fig. No: 1). The Table 2 shows ADF test results reveal mixed integration orders. ED, EG, POP, and FDI are integrated at order I(1), while REC and OP are stationary at I(0). No variable is integrated at I(2), confirming ARDL's suitability. This ensures the data are statistically sound for long-run and short-run estimations without spurious regressions. Fig. No: 2 ACF and PACF Plots indicates ADF Unit Root Test Results. Table 3 of Long-run estimates indicate that renewable energy (–0.048***) significantly reduces environmental degradation, validating its role in sustainable development. Conversely, EG (0.035**), POP (0.021**), FDI (0.017**), and OP (0.025***) exacerbate degradation, suggesting that economic expansion, capital inflows, and oil

dependency strain ecological balance. The positive constant indicates an inherent environmental burden regardless of other factors. Scatter Plot shows ARDL Long-Run Coefficients (Fig. No: 3). The table 4 shows in the short run, REC (0.021*) and OP (0.018**) increase environmental degradation, reflecting inefficiencies and transitional fossil fuel reliance. Population shows a negative impact (–0.014**), possibly linked to urbanization-driven efficiency. EG and FDI have weak, insignificant effects. The significant and negative ECM (–0.48***) confirms strong convergence to equilibrium, with 48% of disequilibria corrected annually. The Table 5 Diagnostic tests validate the robustness of the ARDL model. No evidence of serial correlation, heteroskedasticity, or non-normal residuals was detected, and the stability tests (CUSUM) confirmed model stability. This strengthens confidence in the reliability of the results. Histogram of Residuals shows ARDL Diagnostic Tests (Fig. No: 5). The Table 6 indicates Causality results show unidirectional links: EG → ED and REC → ED indicate that both growth and renewable energy drive environmental changes. ED → FDI suggests environmental degradation influences capital inflows, while FDI → EG demonstrates investment-led growth. No causality was found from POP or OP to ED, highlighting their indirect roles. Table 7 Comparison reveals critical dynamics. EG has no significant short-run impact but increases ED long term. REC worsens ED short term but reduces it long term, underscoring transitional inefficiencies. POP reduces ED short term but aggravates it long term, reflecting demographic pressures. FDI and OP both worsen ED in the long run. This contrast highlights policy needs for green FDI, cleaner oil alternatives, and efficient renewable adoption.

CONCLUSION

This study explored the dynamic relationship between economic growth, renewable energy consumption, and environmental degradation in India from 1990 to 2020 using ARDL and Granger causality techniques. The results demonstrate that renewable energy consumption, while considered environmentally friendly, has paradoxically contributed to environmental degradation in both the short and long run, possibly due to inefficiencies in renewable infrastructure and transitional dependence on hybrid energy systems. Economic growth showed a mild positive association with environmental degradation in the short run, highlighting the challenges of sustaining growth without ecological compromise. Long-term findings revealed that factors such as population growth, oil prices, and foreign direct investment significantly aggravated environmental degradation, reflecting structural and policy gaps in India's sustainable development pathway. The causality results confirmed unidirectional relationships between economic growth and environmental degradation, renewable energy and environmental degradation, as well as between foreign direct investment and both environmental degradation and economic growth. These findings underscore the need for effective policy interventions that enhance the efficiency of renewable energy, strengthen regulatory frameworks, and align FDI inflows with green technologies. Overall, the study concludes that while renewable energy expansion is vital, its environmental benefits in India can only be realized through improved technology, institutional reforms, and integrative policies that balance economic growth with ecological sustainability.

Policy Suggestions

Enhance Efficiency of Renewable Energy Systems: While renewable energy demonstrates long-term benefits, short-term results suggest inefficiencies. India should strengthen renewable infrastructure by investing in smart grids, storage technologies, and decentralized renewable systems (IRENA, 2020).

Green-Oriented FDI Regulations: Since FDI inflows exacerbate environmental degradation, India should channel FDI into clean energy and green technologies. Policymakers can implement tax incentives for environmentally sustainable projects and enforce stricter environmental compliance for polluting investments (Zarsky, 2011).

Balanced Economic Growth with Sustainability: Economic growth has a dual effect—slightly harmful in the short run but beneficial in the long run. Thus, adopting green growth strategies, such as promoting renewable energy-intensive industries and energy efficiency programs, can reconcile growth with ecological preservation (OECD, 2011).

Mitigating Oil Price Dependency: Rising oil prices significantly contribute to environmental degradation. Diversifying the energy mix by scaling up solar, wind, and bioenergy production can reduce fossil fuel dependence and environmental risks (Bhattacharya *et al*., 2016).

Population and Urbanization Management: Population growth has mixed effects on environmental outcomes. Sustainable urban planning, public transport expansion, and energy-efficient housing can help mitigate ecological stress while accommodating demographic growth (UN-Habitat, 2020).

LIMITATIONS OF THE STUDY

Despite providing valuable insights, this study has certain limitations that need to be acknowledged. First, the analysis is limited to secondary data from 1990–2020, which may not fully capture recent structural changes in India's energy sector, especially post-2020 policy reforms (World Bank, 2021). Second, environmental degradation was primarily proxied through CO_2 emissions, which, while widely used, may not encompass other dimensions such as deforestation, water pollution, and biodiversity loss (Shahbaz *et al*., 2013). Third, the ARDL and Granger causality models, though robust, may not fully account for potential structural breaks and nonlinear dynamics in the energy-growth-environment nexus (Pesaran *et al*., 2001). Fourth, the study did not distinguish between different types of renewable energy sources, treating them as a single aggregate, which may obscure the heterogeneous effects of solar, wind, and hydro energy (Apergis and Payne, 2010). Hence, the findings should be interpreted with caution in the context of these methodological and data constraints.

SCOPE FOR FURTHER RESEARCH

Future research can broaden the scope of this study by incorporating more comprehensive measures of environmental degradation beyond CO_2 emissions, such as ecological footprint, air quality indices, and biodiversity indicators (Wackernagel *et al*., 2002). Additionally, sectoral analysis distinguishing between solar, wind, hydro, and biomass energy could provide deeper insights into the heterogeneous effects of renewable sources on environmental quality (Sadorsky, 2009). Advanced econometric approaches, such as nonlinear ARDL or panel data models, can be employed to capture structural breaks, regional disparities, and nonlinear dynamics within India's energy–growth–environment nexus (Shin *et al*., 2014). Moreover, expanding the timeframe beyond 2020 would allow the assessment of recent government initiatives like the National Solar Mission and India's commitments under the Paris Agreement. Finally, comparative studies across emerging economies could enrich the understanding of cross-country policy effectiveness, offering valuable lessons for sustainable energy transitions.

ACKNOWLEDGEMENT

I extend my heartfelt gratitude to my supervisor, the study participants, and everyone who offered their unwavering support. Their insightful guidance, generous cooperation, and constant encouragement were instrumental in the successful completion of this research on the health and stress of women employees in the banking sector.

Funding

This study was carried out independently, without receiving any financial support from external sources.

Conflict Of Interest

The author declares no conflicts of interest, and this study was conducted independently, without any institutional, financial, or organizational support.

ABSTRACT

This article aims to map the research landscape of the virtual reality research in library from 2015-2024. Using citation and co-citation analysis, this work also aims to assist researchers in identifying significant publications, prominent authors, and the relationships between country and affiliations. By examining the 55800 cited references with 1715 documents from journals and conference proceedings relating to virtual reality and library into the Scopus database, employs co-citation and network analysis to investigate the knowledge network. This study provided a broader view of the academic fields outside of computer science. According to the local viewpoint, earlier research projects that involved the international scientific community were limited to the early stages of the epidemic's propagation and examined a small number of scholarly publications. Descriptive and performance mapping, citation, and network mapping, are included in the whole finding which highlight the collaboration network among them. The first element includes annual trend of academic output, as well as production by country and affiliation. Top authors, sources, and documents based on their impact, citation, and creation are the second consideration. Finally, the network mapping incorporates keyword and co-citation analysis, as well as co-authorship with countries and authors. This study offers a platform for assessing publications on virtual reality research in the field of library and a methodical objective to assess the relative significance of the various information and nodes.

Keywords: Virtual Reality, Augmented Reality, Computer Application, Library, Bibliometrics, Altmetric, Citation Mapping,

INTRODUCTION

The integration of virtual reality (VR) technologies into library science has emerged as a significant area of research over the past decade. This period has witnessed a remarkable evolution in how libraries utilize VR to enhance user experience, facilitate learning, and provide innovative services (Muskhir et at., 2024). As libraries strive to remain relevant in an increasingly digital world, the adoption of VR technologies offers new avenues for engagement and information dissemination (López-Belmonte *et al*., 2020).The virtual reality transport library users to historical epochs, firsthand experience of virtual tour of library and historic places. However, libraries are utilizing VR technology to digitize their collection to create virtual library and archives. While digitizing the historic manuscript and artifacts libraries can preserve cultural heritage and make it accessible to a global audience.However, the implementation and accessibility of VR technology in library also have some challenges. The library must ensure that these technologies are comprehensive and helpful to users with diverse learning preferences.Moreover, the exploration of VR in library science is situated within a broader discourse on the role of Information and Communication Technology (ICT) in education(Giang *et al*., 2024). As libraries rapidly adopt ICT which address the equity and accessibility to ensure that all users can benefit from these innovations (Ram *et al*., 2023). The ICT has significantly transformed the landscape of library services, which shifted from repository of physical books to maintain the digital contents. Integration of IoT, AR, VR, and AI revolutionize the library with resource accessibility, user engagement, and technology enhancement. The convergence of IoT and libraries is revolutionizing the space into smart and connected environment that prioritizes user experience and efficiency. IoT enables services and application the way libraries serve their users. This technology is inbuilt with automated circulation, OPAC Kiosk, Security Gate, which reduce human involvement and improve the succession rate (Felton and Felton, 2024). The study suggests that while VR holds great potential and careful consideration must be given to the diverse needs of library users (Czimre *et al*., 2024). The current study in bibliometric overview serves as a valuable tool for mapping the landscape of VR research within library science, allowing for a comprehensive analysis of publication trends, influential authors, and key themes of research.

It highlighted the transformative potential of VR technology in libraries to promote education and research. The research indicates that VR can significantly enhance user engagement and learning outcomes by providing immersive experiences of reproduction in traditional methods(Barry and Kanematsu, 2022). The various studies on bibliometric analysis align with the broader trend of integrating emerging technologies in libraries(Mitha and Omarsaib, 2024). The studies reveal a growing body of literature that not only examines the applications of VR but also identifies gaps and challenges its implementation in library. The bibliometric analysis of VR research in library science is particularly relevant as it sheds light on the collaborative networks among researchers and institutions. Through the analyzing of citation patterns and co-authorship, researchers can identify leading contributors in the field. This approach not only highlights the academic impact of VR research but also informs future directions for further inquiry and practices. For example, a bibliometric study on augmented reality and VR technologies has underscored the importance of interdisciplinary collaboration in advancing research and application (Fortuna *et al*., 2024).Another important component in metric is Altmetric also known as the alternative metric. Alternative metrics are referred to differentiate them from bibliometrics and Scientometric (Gunn, 2013). It is regarded as a fascinating alternative for evaluating the societal impact of research. It is provide a novel method for measuring public engagement with research output (Piwowar, 2013). Altmetric is a term that refers to web-based metrics, which evaluate the impact of scholarly material, with a particular focus on social media and other online sources. The mapping of VR research in library science from 2015-2024 reveals a dynamic and evolving field that is composed to shape the future of library services. Through bibliometric analysis, researchers can gain insights into the trends, challenges, and opportunities that define this landscape (Rojas-Sánchez *et al*., 2022). As libraries continue to explore the potential of VR technologies, ongoing research will be essential in guiding effective implementation and maximizing the benefits for users. The results of this bibliometric analysis will contribute to scholarly discourse and serve as a practical resource for library personnel aiming to innovate and improve their services in a progressive digital environment.

SCOPE OF THE STUDY

The present study examines virtual reality research in libraries using performance and network analysis approaches within the field of scientific investigation. These approaches are based on the principles of bibliometrics, altimetric and science mapping. Science maps are graphical representations that illustrate the relationships among various disciplines and specialties. These maps serves multiple purposes of scholarly treatise (Small 1999; Bales *et al*. 2020). A bibliometric map is crucial element of this research, which are constructed and utilizing citation data using this technique (Buter *et al*. 2006). The trinity of bibliometric analysis pertinent to the practice of science mapping includes citation analysis, co-authorship analysis and co-citation analysis. The examination of co-citation denotes the frequency which is mentioned synchronously and produces significant insights into the academic field. The examination of co-authorship in academic research highlights the relationships between authors and their affiliations, uncovering the intricate social dynamics inside and collaborative networks (Bales *et al*. 2020; Buter *et al*. 2006; Noyons *et al*. 2006).

BIBLIOMETRIC ANALYSIS

Bibliometric analysis is a quantitative research method used to evaluate and analyze scientific literature. It involves the statistical examination of publications, focusing on aspects such as citation patterns, authorship, and the impact of research within specific fields (Linnenluecke *et al*., 2019). This method helps identify research trends, collaborations, and the overall influence of scholarly work.It providing the insights into the development of knowledge over time (Passas, 2024). The process typically includes data collection from various databases, followed by the application of bibliometric indicators such as citation counts, h-index, impact factors, etc (Passas, 2024). These indicators serve to measure the visibility and significance of research outputs. Bibliometric analysis can also reveal the structure of research networks and the evolution of topics, making it a valuable tool for researchers, policymakers, and academic institutions (Agarwal *et al*., 2016).It is essential for understanding the dynamic of scientific communication and the impact of research which plays a crucial role in the assessment of research quality and productivity(Sandvoll, 2024). "Bibliometric Analysis" can be defined as an exertion to handle extensive material through standardization, illustrating trends and structural arrangement within a scientific study. This review concerns the intellectual structure, co-authorship patterns, and research trends of the literature in quantifiable form. This method seems particularly suitable for comprehensive reviews using extensive literature for effectively mapping a study domain; identifying pivotal publications, authors, and journals that shaped discourse; and understanding the evolution of research themes over time. The bibliometric analysis is considerably less appropriate for targeted reviews for small and manageable datasets. The quantitative aspect fails to adequately represent the intricate characteristics of a clearly articulated research issue. The scope of this bibliometric analysis is extensive, encompassing hundreds or even thousands of articles across many databases to ensure diligence in a certain topic. A bibliometric study often encompasses quantitative content analysis employing content analysis related to the frequency of keywords (Nasir and Jana, 2025).

METHODOLOGY OF THE STUDY

Bibliometrics are systematically employed techniques that examine huge volumes of scientific data (Donthu *et al*., 2021). Thus, a bibliometric analysis examine a topic of scholarly productivity within a specific field (Mishra *et al*., 2022; Siddique *et al*., 2023; Nugroho *et al*., 2023). Furthermore, other enquiries arise from a bibliometric analysis, including the correlation between the volume of publications and their trending keyword. This study uses scientific mapping and performance analysis of 1,715 articles inScopus database from 2015-2024.It employed a dual methodology, Initially the pertinent citation databases were chosen, and the researchers apply search algorithms with two keywords "Virtual Reality" and "Library" with the filtering criteria English language, article only, social science subject, and 2015–2024 time frame. Secondly the data analysis using bibliometric tools R (Biblioshiny) and VosViewer (Wang, 2023)software and finally use Open Science Platform for identify the Altmetric score.

Research questions

RQ1 What is the global research trend in the field of virtual reality and library between 2015 and 2024?

RQ2 Find out the leading authors, Journals and Countries that have enthusiastically contributed to virtual reality research in the field of libraries?

RQ3 To analyze the collaboration of authors with countries, and institutions.

RQ4 Which are the most trending keywords in virtual reality research in the field of library?

RESULT

The comprehensive dataset was extracted from the SCOPUS database covering the years 2015 to 2024. Figure 1 highlights that 1,715 articles are distributed among 1015 sources, with an annual growth rate of 9.64%. A total of 6,289 authors contributed their work across the decade. The total number of citations accrued by 1,715 articles is 21,369, producing an average of 12.46 citations per document.

Annual Growth: A total of 1,715documents were published in the "Virtual Reality" and "Library" during the 10-years of study period. Figure 2 shows the year-wise distribution of articles published along with their respective citations. The number of documents increased steadily from 2023 with the highest growth [254 documents] followed by 2024 [245 documents].

Table 1 also indicated the total publication, annual citation, and average citation of documents published over the years. The maximum number of citations occurred in 2020 [4518], followed by 2015 [4260], only 316 citations counted in 2024. As per the average citation the highest per article citation is counted in 2015 [39.81]which highlight the quality of articles. Whereas 2020 has the highest number of citations, the average citation per manuscript is lower than 2015. While in 2024, relatively few citations were received due to the most recent year of publication. Generally, citations are not received immediately after publishing.

Authors Co-relation: Figure 3 has indicate the plot of co-relation between authors with their country with affiliation. There are 10 authors from 4 affiliated institute and 6 countries. All 10 authors are belong from China, and their collaboration work with USA, Germany, Italy, United Kingdom, and Korea. The author Zhang, Y who have collaborate with USA and UK, but basically belong from China Pharmaceutical University. Followed by Wang, Y who have collaboration with all four institutes "University of Jinan", "China Pharmaceutical University", "Central South University", "Huazhong University of Science and Technology" and the country like USA and Italy. The author Li J, Li Z, Liu Y, don't have any co-relation between these four institutes.

Top Cited Source: Table 2 describes the research output by relevant sources. There are top five sources are selected according to their publication. The first observation is that "Lecture Notes in Computer Science" consist highest number of documents [54 documents] with 339 citations. Followed by "ACM International Conference Proceeding Series" produced 40 documents with 102 citations. According to citations PLOS One journal are getting more citation (727 citations). This study describes that journal articles are getting more citation compare to lecture notes and conference proceedings. Because of PLOS One is getting more citation while the H-Index is also high which indicate the consistency of research.

Most Relevant Authors: Table 3 represents the top ten authors who have contributed more research documents during the period. The top ten contributions have been taken into account with a view to avoid a long list. The authors having same number of contributions have been listed last of the list. The ranking of authors has great importance in Bibliometric research. Zhang Y, is the most dominating author with highest number of articles and Li J, is another dominating author with highest citation. According to the citation and H-Index Li, J securing the highest citation and only five H-Index, which indicates the consistency of research. Followed by Zhang J securing 321 citations with 6 H-Index. Figure 4 has highlight the trend line of H and G-Index of top 10 authors with their highest

number of publications. Accordingly, Li J has the highest G-Index (16) and moderate H-Index (5). Followed by Li X have highest H-Index (6) and third highest G-Index (13). The trendline represents the authors' lower H ad G index according to their publication. However, the top publication secures the highest indexes.

Country Distribution: There have been 1,715 publications in this field of study from 113 countries of 2015-2025. The majority of countries are developed countries, with few developing countries are included. China, is most prominent countries among developed nations with 265 articles followed by USA (n=138) came after China. Among the developing nations, India (n = 105), Italy (n = 62), Germany (n = 40), and United Kingdom (n = 32) securing the following positions. According to citation the United States secure most citations (TC = 2505), followed by China ranked second (TC = 2152). According to average citations United Kingdom has secure highest average citation (AC=22.75) followed by USA, Canada, and Italy. The average citation is describing the per article citation over the years, which is directly impact on authors and countries productivity and metric. The ratio of SCP and MCP of total publication highlight that China, USA, Korea, Brazil are publishing more articles in their own country. Whereas United Kingdom and Canada are publishing almost equal publication with single and multi-author publication.
Table 4: Top Country Production *(Note: "SCP: Single Country Production, MCP: Multiple Country Production")*

Most Cited Documents with Altmetric Score: Table 5 outlines the most cited documents with their Altmetric score in the observed sample. The Altmetric score for research is provides an indicator of the amount of attention received by particular article from social media and other open source platforms. "The score is derived from an automated algorithm which represent a weighted count of the amount of attention that is picked up for a research output". The most cited paper "Small-Molecule Library Screening by Docking with PyRx" getting 2,395 citations by the 217.73 average citation per year. Followed by "A systematic review of immersive virtual reality applications for higher education: Design elements, lessons learned, and research agenda" getting 1,619 citations with 269.83 average citation per year. The "Effects of virtual reality rehabilitation training on gait and balance in patients with Parkinson's disease: A systematic review" is getting a smaller number of citation (148) with the average number of citations is 21.14. However, the article "An open-source drug discovery platform enables ultra-large virtual screens" by Gorgulla, C have maximum number of Altmetric score which indicate that particular article is mostly available in public domain. Which is easy to accessible for all the researchers. Basically, the altmetric score are not indicating the quality of a research work. The attention some time may be negative but in altmetric score it also counted. So, the altmetric score not completely reliable to define the quality of a research article.

Co-Authorship Network: Figure 5 illustrates the international collaboration network in this research domain. In the figure, nodes represent contributing countries, while the connecting lines indicate interactions or co-authorship among them. The nodes together form a network of collaborating countries. The colours of the nodes denote distinct clusters based on publication patterns, and the colours of the connecting lines follow the same principle. The size of each node, represented by rings, reflects the relative importance of that country in the network. The visualization highlights that the United States, China, India, Germany, and the United Kingdom have shown steady progress over the past decade, consistently contributing a significant volume of publications. Among these, the United States, China, and India are particularly active in fostering collaborations with other countries. Table 4 lists the ten most productive countries in terms of publications. China leads with 265 publications, playing a pivotal role in this field. The United States (138) and India (105) hold the second and third positions, respectively. Notably, the publication output shows considerable disparity among the top countries, with nearly a twofold difference between successive ranks. The collaborative network is divided into three major clusters comprising 55 countries: 26 in the first cluster, 22 in the second, and 7 in the third. Within the first cluster, the United States, China, and India dominate in terms of co-authorship, reflecting their central influence on international research collaboration.

Co-Authorship among Organizations: The examination of all articles identified 3,856 research institutes, with the results and collaborations illustrated in Figure 6. Analysis of the nodes and connections indicates that Science and Intelligence Research often collaborate with institutions in China, the USA, and Germany from 2015 to 2024. Furthermore, Indian domestic agencies have collaborated on research consistently since 2013.

Keyword Analysis: The keyword analysis is most important in bibliometric analysis. It highlights the most recent and trending research keywords regarding the specific study term. The analysis, illustrated in Figure 7, employs as the keywords node and is visualized using VosViewer software. Each node signifies a different keyword, and the line connecting two indicates co-occurrence between keywords. In this study, there are 5, 4808 author keywords, whereas 164 meet the threshold for this analysis with the limit of minimum 5 keyword per article. A total of three clusters consists of 164 items, first (132), 2nd (21) and 3rd (11). The large cluster highlight with red colour and the most frequent keyword in virtual reality, augmented reality, metaverse and so on. The 2nd cluster highlights green colour and the most occurred keyword in virtual screening, followed by molecular docking. Finaly and 3rd cluster are indicate with blue colour and virtualization is the most occurred keywords.

Co-Citation among Authors: The VosViewer tool may rationally comprehend a coherent and structured of knowledge structure by analyzing and visualizing a scientific study field. This strategy is well known as a useful bibliometric technique for revealing hidden implications in vast amounts of data. Furthermore, VosViewer is an effective tool for knowledge mapping and creates a variety of network maps in a methodical manner. Thus, this systematic review uses abstract clustering analysis and builds a co-citation network from the data. The relationship between authors whose works are referenced in the same document is shown by the author co-citation network. Figure 8 displays the author's network of co-citations. The criteria fixed with minimum number of citations per author is 20, total 113197 author with 492 met the threshold. Cluster 1 consist of 335 authors, cluster 2 (147), and cluster 3 (10). The author Zhang Y, and Wang Y from cluster 1 has maximum number of ci-cited network with other authors. Iriwin J.J, and Olson A.J, from 2nd cluster have a greater number of co-cited network, and the third and final cluster Slater, M have maximum co-cited network.

DISCUSSION

R (Biblioshiny) and VosViewer were used to perform a bibliometric analysis of the publications related to "Virtual Reality" in "Library" that were published between 2015 to 2024. As of the end of 2024, it was found 1,715 documents published on these keywords. The publication's output grew between 2012 and 2021, reaching its highest point in that year. The output of publications increased by 9.64% annually, whereas 2023 is the largest growth year, suggesting that interest in this field of study is increasing day to day. The study contained 21,369 total citations, with an average of 12.46 citations per document. The top ten cited papers summarised the current results regarding the relationship between virtual reality and libraries represented the most recent findings. A total of 113 nations made contributions to this field of study. China, the United States, and India were the top three nations those are published more than 100 article each. It should be mentioned that, out of all the nations, China had the most publications, citations, and links to other nations. The fact that China and the United States are the only developed nations in the top three with the research capacity limitations of developing nations. According o the source analysis1015 sources were used in the study, and the top 10 were categorised as "Lecture Notes in Computer Science (Including Subseries Lecture Notes in Artificial Intelligence and Lecture Notes in Bioinformatics)", "ACM International Conference Proceeding Series", "CEUR Workshop Proceedings", "Journal of Biomolecular Structure and Dynamics", and "PLOS One." Of the top five sources, four are journals, and one is a conference proceeding, which can hold 1,715 documents. In our study, 6,289 authors contributed to 1,715 publications. The top five authors in this field of study were Zhang Y (n = 20), Li J (n = 16), Wang Y (n = 16), Chen Y (n = 15), and Li X (n = 13). Li J got the best g-index and Zhang Y had the highest h-index, indicating that the researcher was successful in this field. In the research on virtual reality in libraries published between 2015 and 2024, 164 keywords with more than five occurrences were used. This area of study was separated into three clusters using cluster analysis of co-occurrence keywords. 132 keywords were included in Cluster 1. With 21 terms in Cluster 2 and just 11 in Cluster 3, the attention is mostly on the connection between virtual reality and libraries. Among the authors, Zhang Y is the most frequently cited, according to the co-authorship pattern.

CONCLUSION

This study provided a broader view of the phenomenon's wide-ranging and unpredictable impact on academic fields outside of computer science. According to the local viewpoint, earlier research projects that involved the international scientific community were limited to the early stages of the epidemic's propagation and only examined a small number of scholarly publications. Additionally, this was the first time that the study of the impact on research production was connected to virtual reality research in a library setting. There are several restrictions on this work. Some documents' precise publishing dates may differ from those found in Scopus, which merely provides the issue's publication date. This could lead to a greater parameterised number of citations and an underestimating of a scientific document's longevity. Additionally, with reference to the data set analyses. In the future, we intend to investigate the impact factor's role in predicting the number of citations when examining articles that address issues that may have consequences that are on par with or even more pertinent than those of virtual reality in libraries over a longer period of time, like the study of library innovation. One of the most significant findings of this study is rise of research output during the period indicating that VR technology is increase in library operations. The countries such as China, United States, and India have emerged as leading contributors to support robust collaboration among them. In the recent trends LIS professionals, educators, researchers are continuous engaging with VR technology to provide seamless user services. The network analysis reveals distinct clusters of research from VR applications in information literacy, immersive learning environments, digital heritage preservation, and user experience. These clusters reflect not only the technological possibilities of VR but also the LIS community's responsiveness to societal needs, such as inclusive learning and equitable access to emerging technologies. The inclusion of altmetric analysis provides an added coating of understanding, bridging the gap between scholarly output and societal attention. While citation-based bibliometrics measure academic influence, altmetric indicators capture public engagement, policy, and professional interest. The findings suggest that VR research in library science is not only academically robust but also socially visible, particularly in professional networks and online platforms. This study contributes to the consistent body of knowledge on digital transformation in LIS by mapping the trajectory of VR research over the past decade. It sustains that VR is not an isolated trend but part of a larger movement toward immersive, technology-driven knowledge services in libraries. By combining bibliometric indicators with altmetric scores, the study provides a holistic understanding of how VR research influences both scholarly communities and wider society. The findings underscore the importance of sustained international collaboration, policy support, and inclusive innovation to ensure that VR technologies serve diverse user populations.

ABSTRACT

Pattern recognition has evolved from handcrafted features to deep, data-driven representations and, recently, to foundation models trained at scale. This paper (i) surveys advances from 2023–2025 relevant to traffic crash detection, anticipation, and risk prediction; (ii) synthesizes trends across video anomaly detection, time-series forecasting, and graph-based road network modeling; and (iii) proposes MM-ARD, a Multimodal Accident Risk & Detection framework that fuses road-network graphs, time-series sensor data, historical crashes, weather, vision features from foundation models, and wearable airbag data. We outline an evaluation protocol with modern datasets and metrics, discuss deployment and explainability challenges, and provide an open, reproducible research plan.

Keywords: Pattern recognition, foundation models, video anomaly detection, traffic crash prediction, graph neural networks, transformers, self-supervised learning, wearable airbags

INTRODUCTION

Traffic accidents remain among the leading causes of death and injury worldwide. Despite advancements in intelligent transportation systems, real-time crash prediction and detection remain challenging because of their inherent rarity and unpredictability. However, recent breakthroughs in pattern recognition—especially the emergence of large, pretrained foundation models capable of learning generalized multimodal representations—have

renewed optimism for progress in this area. This work contributes in three ways. First, it reviews recent advancements in pattern recognition from 2023 to 2025 and their relevance to crash detection. Second, it consolidates emerging research trends across three interconnected domains: video anomaly detection, time-series risk estimation, and graph-based road network representation. Third, it proposes MM-ARD, a multimodal framework that integrates heterogeneous data sources for joint crash detection and accident risk prediction.

Advancements In Pattern Recognition (2023–2025)

Foundation Models For Vision And Multimodal Learning

From 2023 to 2025, computer vision research was largely driven by foundation models such as Vision Transformers (ViTs), CLIP-like multimodal encoders, and spatiotemporal networks pretrained on petascale-scale video datasets. These models provide robust capabilities for recognizing unusual events in continuous video streams—an essential component for proactive traffic accident anticipation.

Time-Series And Sequential Forecasting

Transformer architectures replaced recurrent neural networks as the dominant paradigm for traffic prediction and sensor data modeling. Key innovations include masked autoencoder pretraining and diffusion-based sequence modeling, which significantly improved long-horizon forecasting and uncertainty quantification in crash risk estimation tasks.

Graph Neural Networks And Road Networks

Graph neural networks (GNNs) advanced rapidly in the representation of structured spatial data, including complex road networks. Between 2023 and 2025, scalable hypergraph transformers and dynamic spatio-temporal GNNs enabled effective modeling of city-scale mobility patterns and the dynamic variations within high-risk traffic zones.

Trends In Connected Fields

Video Anomaly Detection

Recent research frames traffic accidents as rare anomalies within continuous traffic video streams. The dominant methods include:

- Contrastive video representation learning with self-supervised objectives.
- Diffusion-based generative modeling for distinguishing normal from anomalous frames.
- Zero-shot event detection using cross-domain representation transfer from large foundation models.

Time-Series Crash Risk Prediction

Crash prediction relies more on diverse signals such as vehicle telemetry, accident data, weather conditions, and road status. Current methods focus on:

- Estimating uncertainty using probabilistic transformers.
- Using meta-learning techniques to apply insights across different areas.
- Combining driver behavior observations with past accident records.

Graph-Based Modeling Of Urban Road Networks

Graph-based techniques allow for localized accident forecasting by merging the structural details of road networks with the timing of crashes. New strategies include spectral hypergraph learning and spatio-temporal attention networks.

MM-ARD Framework

We present the MM-ARD (Multimodal Accident Risk & Detection) framework as a unified process that includes various types of data:

- Road-Network Graphs: Represented using GNNs along with dynamic spatio-temporal embeddings.
- Time-Series Sensor Data: Managed using long-sequence transformers enhanced with probabilistic forecasting.

• Historical Crash Records: Used for pretraining embeddings that indicate crash risk.
• Environmental and Weather Features: Integrated with context-aware attention modules.
• Vision Features: Gathered from large pretrained vision-language models for video crash detection.
• Wearable Airbag Data: Used as early warning signals for rider safety, which can extend to vulnerable road users.
The fusion of these modalities is built on a transformer backbone, with specific encoders going through a cross-attention combination network.

Evaluation protocol:
To ensure reproducibility and broad use, we outline a detailed evaluation strategy:
• Datasets: New large-scale open benchmarks such as DoTA (Driving Outlier Traffic Anomalies), TRAF (Traffic Risk Anticipation Framework datasets), and citywide crash databases (2023–2025).
• Metrics:
- Event detection: AUC, F1-score, frame-level versus event-level precision.
- Forecasting: RMSE, CRPS (Continuous Ranked Probability Score), and calibration error.
- Deployment metrics: latency, robustness with missing data, and scalability in different cities.

Deployment And Explainability Challenges
Several challenges remain for implementing real-world MM-ARD:
• Understanding the reasons behind expected crash risks is crucial. Recent innovations in counterfactual explanations for GNNs and video transformers need to be customized.
• Data Privacy: The mix of wearable and sensor data raises concerns about privacy and fairness.
• Scalability: Real-time traffic model inference remains computationally expensive.
• Domain Generalization: Transferring models across regions requires adaptation and ongoing learning mechanisms.

Open Research Plan
To foster reproducibility and transparency, our research plan includes:
• Open Benchmarking: Publishing standardized annotations for multimodal datasets.
• Model Cards and Transparency Reports: Keeping records of trained models along with ethical and technical advice.
• Community Collaboration: Providing toolkits to integrate wearable and infrastructure sensors.
• Simulation-to-Real Transfer: Creating synthetic crash scenarios with simulation tools to supplement rare, high-risk cases.

CONCLUSION

From 2023-2025, pattern recognition has transformed through foundation models, multimodal learning, and graph reasoning. Our proposed MM-ARD framework leverages these advancements for traffic crash detection and prediction. By integrating vision, sensor, graph, environment, and wearable data, it aims to create safer and more understandable intelligent transport systems.

ABSTRACT

As the healthcare sector continues to experience increased service demands, staff shortages, and the effects of global crises, the need for workforce resilience has become vital. Usually, methods that focus on training and coping skills tend to undervalue the technological innovation potential. This research presents a conceptual framework that combines Artificial Intelligence (AI) and Knowledge Discovery (KD) to empower resilience at the individual, organizational, and systemic levels. AI learns to anticipate risks to the workforce like stress and burnout, while KD unearths the latent patterns in behavior and decision-making. Together, they facilitate the early, data-driven management and organizational agility. The model emphasizes that AI is a tool that complements human skills and does not replace them, thus resulting in employee retention, good mental health, and healthcare sustainability. Some of the instances

are burnout detection with AI assistance, predictive workforce planning, and the administrative task automation. The framework offers theoretical support to the research community, hospital management, and policy makers in integrating AI and KD ethically to provide a healthcare system that is resilient and ready for the future.

Keywords: Adaptive healthcare systems; artificial intelligence; healthcare; knowledge discovery; workforce resilience.

INTRODUCTION

Healthcare systems around the world are still facing many challenges, such as growing demand, a shortage of healthcare workers, the lasting effects of global health crises and the need to balance economic goals with public health needs. In such a scenario, the resilience of the workforce, which can be explained as the ability of both individuals and organizations to adapt, recover, and continue to operate efficiently under pressure, is extremely important. Even before the recent technology boom and the factors that drove it, the main topics of the resilience research have always been human capacity, coping, and the creation of support and leadership systems. These elements are still essential, but technological innovations such as artificial intelligence, which anticipates workforce risks, burnout, and workload distributions, and knowledge discovery, which facilitates learning for the organization, are opening new ways for resilience. These technological innovations give organizations the opportunity to move from reactive to proactive strategies. This proactive position broadens the concept of resilience to also include technological and other systemic factors along with the psychological components of individual resilience.

REVIEW OF LITERATURE

Resilience is seen as a multi-level concept. One group of scholars illustrate that resilience being a capability has a very energetic character and it is determined by leadership, institutional processes, and organizational learning [1]. Another group of scholars consider that resilience surpasses the individual and is influenced by the technological and structural environments. Artificial intelligence is increasingly linked with the healthcare system's resilience. Some studies talk about AI's capacity to improve operational efficiency and thus contribute to achieving other sustainable development goals [3]. The role of AI in the formation of the healthcare ecosystems that are both adaptive and resilient is fundamental [9]. Also, industry reports emphasize that AI is a key factor in relieving the healthcare system from the burdensome administrative tasks so that professionals can focus more on patient care [4]. At the same time, some other research warns that if AI is adopted without proper control, it can cause psychosocial risks and make the healthcare workers' situation more difficult [11]. In addition, knowledge discovery plays a vital role in resilience. Research has shown that AI-powered systems to a great extent facilitate the capturing of tacit knowledge which in turn promotes innovation and continuous learning within a firm. When organizations succeed in embedding informal, experiential knowledge into formal systems, they become more flexible and adaptable to the times [10]. Also, AI's effect on self-regulation and personal resilience is mentioned, and that has both advantages and disadvantages [5]. There are unique ethical and governance concerns when it comes to the implementation of AI in medicine. Worldwide organizations have outlined that the use of AI in health should be characterized by equity, transparency, and justice [7]. Medical Associations have on their part advocated for the imposition of control and trust in AI use [12]. Research has also revealed that trust in AI-powered knowledge systems may lead to more innovation, with workforce resilience being a major moderating variable [8]. Resilience comprises the human factor, the organization's factor, and the technological factor. AI provides a predictive insight at the KD level which is contextualized by both, thus they can be of great help in increasing the resilience of healthcare systems.

OBJECTIVES OF THE STUDY

The research was driven by the objectives that it was first necessary to:

- To describe the healthcare workforce resilience as a complicated multi-layered phenomenon that exists at the individual, organizational, and system levels.
- To explore how the use of artificial intelligence AI and knowledge discovery KD together can help to increase resilience.
- Developing a model that highlights the interrelation of AI and KD as a source of healthcare workforce resilience.

Workforce Resilience in Healthcare

Healthcare resilience means the mental, organizational, and systemic factors that enable people to work in stressful situations. On the personal level, resilience is the coping and adaptation methods an individual can find. On the organizational level, resilience results from the practices of management, staff support, and knowledge management. On the systemic level, resilience is the outcome of infrastructure, governance, and policies. Such a view helps to understand that resilience is not only a personal feature, but a 'resilient' organization and system are also needed (Table-1).

Role of Artificial Intelligence And Knowledge Discovery

Artificial intelligence (AI) improves the capacity to recover from difficulties by providing foresight, evaluating risks in the personnel, and making crisis simulations easier. The system also identifies situations where an employee may be burning out, changes the work that has to be done so that the person is not overburdened, and it makes the task that most people find boring by automating it. Knowledge discovery (KD) is even more powerful when it is combined with these elements because it can find the hidden patterns in behavior, culture, and policies that drive engagement, innovation, and, unfortunately, employee turnover (Table-2). AI and KD have the capacity to convert data into insights, thus strengthening resilience in various dimensions of healthcare.

Conceptual Framework Proposed

The proposed framework considers workforce resilience the culmination of predictive capabilities of AI and the interpretive value of KD.

Individual level: AI assesses risks of stress and burnout, and KD determines personal development paths and coping strategies.

Organizational level: AI analyzes patterns of workload and resources, and KD elucidates the drivers for leadership and employee retention.

Systemic level: AI assesses service demand, resource allocation, and KD determines governance and policy gaps.

This integrated framework (Fig.1) ensures technological tools will not replace human effort, improving resilience and sustainability in healthcare.

DISCUSSION AND IMPLICATIONS

The framework provides healthcare administrators with practical insights. Artificial Intelligence (AI) can locate areas of potential risk and thus, as a result, timely interventions can be initiated. At the same time, knowledge distillation determines the worth of the cultural and behavioral context. Authorities can spot the systemic governance loopholes and lead the ethic use of AI. The framework supplies a theoretical ground for researchers to study the concept of resilience in different dimensions and associate it with real-world indicators such as employee retention, mental health, and patient care quality. This is an affirmative signal of the overall worth of the suggested framework. The very recent crises also serve as a further confirmation to the same effect by the examples of AI dashboards usage in the United Kingdom, which contributed to the allocation of critical care resources and therefore, systemic resilience was strengthened. To counter the effects of the pandemic on hospitals, AI-enabled telemedicine in India was used

and as a result, both healthcare workers and hospitals achieved organizational resilience. Generative AI has been successful in demonstrating the capability of healthcare staff to focus more on patients by reducing the administrative burden in healthcare settings (Table 3).

CONCLUSION

The idea of this research is to present a conceptual framework as a means to locate the crossing of Artificial Intelligence (AI) and Knowledge Discovery (KD) in healthcare as two main factors that can help influence the resilience of the workforce. While AI brings a predictive view, KD through organizational learning and flexibility helps to move adaptive tacit knowledge. In this way, resilience is nurtured at the individual, organizational, and systemic levels. The framework from the research makes clear the role of AI to be the one that supports human expertise and does not replace it. This will help retention, ensure mental health, and safety will be at its best. Research additional should concentrate on the governance, impact, workforce trust, and empirical validation of this model that is the gaps for strengthening sustainable resilience in healthcare.

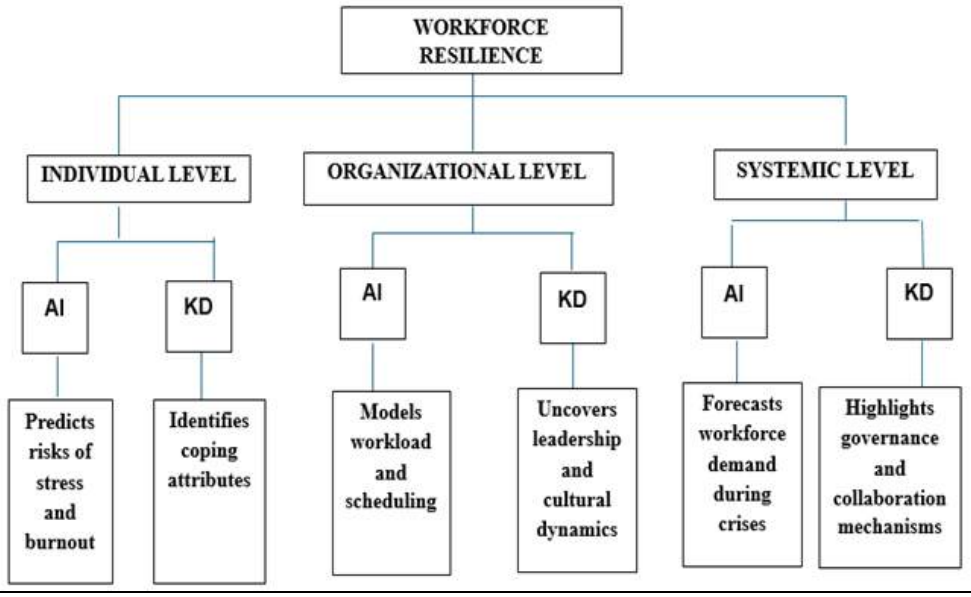
Table No 1: Dimensions of workforce resilience in healthcare

LEVEL	KEY DIMENSIONS	EXAMPLES
Individual	Coping skills adaptability	Stress management, burnout recovery
Organisational	Leadership, support system	Knowledge sharing, staff retention

Systemic	Government policy, infrastructure	Crisis response, resource allocation

Note: This table outlines the three levels of the workforce resilience hierarchy that is individual, organisational, and systemic showing that coping ability, leadership support, and policy infrastructure together provide the resilience of the healthcare sector under pressure.

Table No 2: Role of AI and Knowledge Discovery in Workforce Resilience



FUNCTION	CONTRIBUTION OF AI	CONTRIBUTION OF KD
Risk identification	Early detection of burnout, workload analysis	Interpretation of cultural and behavioural factors
Decision support	Predictive models , clinical assistance	Organisational learning, tacit knowledge sharing
Systematic adaptation	Forecasting demand and resource needs	Government insights, policy improvements

Note: The table describes the contribution of Artificial Intelligence (AI) and Knowledge Discovery (KD) in workforce-resilience functions, such as risk detection, decision support, and enabling system-level adaptation.

Table No 3: Implications of AI and KD for Workforce Resilience

STAKEHOLDER	ROLE OF AI	ROLE OF KD
Administrators	Risk prediction, workload optimization	Insights into staff motivation and culture
Policy makers	Forecasting systemic demand and resources	Governance and ethical guidance
Researchers	Measurement of resilience outcomes	Theoretical integration of tacit and explicit knowledge

Note: The table outlines different roles of AI and KD for the main healthcare stakeholders—administrators, policymakers, and researchers highlighting their joint effect on prediction, governance, and theoretical development of workforce resilience.

Note: The figure illustrates the conceptual integration of AI and KD operations that lead to workforce resilience at individual, organisational, and systemic levels.

ABSTRACT

If you want to see the most evident phenomena of co-existence, look no farther than nature. The basis for treating human ailments are natural materials derived from plants, animals, and minerals. The demand for and general acceptance of medicinal plants is rising. Without a question, plants play a pivotal part by supplying crucial functions to ecosystems. The Acanthaceae is one of the source of medicinal plants with 250 genus and 2500 species. One of the active member among the genus is andrographis. Andrographis comprises about 26 species. *Andrographis echioides* (L.) Nees is an understudied medicinal plant. The present study was performed to investigate the preliminary phytochemical screening and anthelmintic activity of hydroalcoholic extract of *Andrographis echioides* aerial parts. *Andrographis echioides* hydroalcoholic extract were tested for its anthelmintic effects against *Pheritima posthuma* (Indian earthworm) at concentrations of 10mg/ml. 20mg/ml, 30mg/ml, 40mg/ml, and 50mg/ml. Piperazine citrate was used as the reference standard. The time consumed for paralysis and death of the *pheritima posthuma* were calculated for all groups. The results of this study indicate that the hydroalcoholic extract of *Andrographis echioides* aerial parts will have moderate anthelmintic activity. The anthelmintic properties of *Andrographis echioides* extract was found to be less significant as compared to the standard anthelmintic drug Piperazine citrate.

Keywords: *Andrographis echioides*, pheritimaposthuma, piperazine citrate, anthelmintic.

INTRODUCTION

Helminthiasis is a common infections that affects a large part of the world's population. Helminthiasis is a huge health risk, especially in developing countries [1]. This is mostly caused by the lack of clean water and sanitary facilities that come with poverty and lack of education [2]. Helminthiasis affects most people around the world, but it is very common in places like India. This problem is more noticeable in rural areas than in urban ones. The world Health Organization says that roundworms, which are a type of parasitic worm, cause 35% of diseases. More than 1.5 billion people, or 24% of the world's total population have been infected with soil-transmitted helminthes [3]. Parasitic infections continue to be a big problem for livestock production around the world [4]. An anthelmintic drug will kill or stun the parasitic worms (helminths) so that they leave the body. Most of the drugs used to treat helminthes that live in the gastrointestinal stop working on these helminthes [6]. Also, the anthelmintic drugs that are on the market right now are expensive [7]. Because of these things, it is possible to get new worm-killing drugs from plants. Natural medicines, which come from plants, animals, and minerals are one of nature's gifts to people and help fight many diseases [8]. Plants have always been the foundation of traditional medicine, and they have been helping people for thousands of years [9]. *Andrographis echioides* (L.) Nees is a crucial medicinal plant that is widely used around the world. *Andrographis echioides* (L.) Nees is also known as *Indoneesiella echioides* (L.) Nees. This plant is commonly grown in South India and is also known as False Water Willow. *Andrographis echioides* plants are typically found in arid areas like South Asian countries, Sri Lanka, and India. Infections caused by the Indoneesiella species are used to treat goiter, liver diseases [10], problem with fertility, bacterial [11], malarial and fungal infections. To stop hair from falling and becoming grey, the leaf juice is combined with coconut oils and cooked [12]. The present study evaluates the anthelmintic potential of hydroalcoholic extract of *Andrographis echioides* aerial parts against Indian earthworms (*Pheritima posthuma*).

MATERIALS AND METHODS

Plant Material Collection

Andrographis echioides (L.) Nees plants were collected from the Edappadi of Tamilnadu and the same was authentified by Dr. S. S. Hameed Scientist 'E' and Office in charge, Botanical Survey of India, Southern Regional Centre, Coimbatore.

Preparation of Extract

Andrographis echioides aerial parts (leaves, flowers, stems) were collected and then cleaned, shade dried, mechanically grinded. The crude extracts are prepared by Maceration technique. Coarsely powdered plant materials were separately soaked in extraction solvent hydroalcoholic (ethanol:water(50:50)) followed by shaking periodically for seven days and then filtered. The extract are then dried in hot air oven and transferred into well labelled vials and kept in a refrigerator until required for use. The resulting dry extract was weighed and provided a percentage yield of 18.75% (w/w).

Phytochemical Screening

The hydroalcoholic extract of *Andrographis echioides* aerial parts were screened for their phytochemical composition in order to determine their qualitative chemical components. The components were screened using conventional protocol, procedure and reagents, as described in Trease and Evans [13] and sofowora [14].

Collection of Parasites

Earthworms shows resemblance in its anatomical and physiological nature similar to that of human intestinal roundworms [15-17]. Earthworms were obtained from mucky soil, cleaned and separately by size and length before being employed in the experiment.

Anthelmintic studies

Uniformly sized earthworms (*Pheritima posthuma*) were chosen for the investigation (3-5 cm in length and 0.1-0.2cm in width). Earthworms were released in 11 groups of three into 10 ml of their preferred solutions. Group I is the control (normal saline). Groups II-VI received 10mg/ml, 20mg/ml, 30mg/ml, 40mg/ml, and 50mg/ml of *Andrographis echioides* hydroalcoholic extract. Piperazine citrate 10mg/ml, 20mg/ml, 30mg/ml, 40mg/mL and 50mg/ml were administered to groups VI through XI. Each batch of earthworms was monitored for up to 300 minutes, and the time it look for the worms to become paralyzed and death was recorded. It was established that the earthworms had been paralyzed since they did not recover after being placed in a normal saline solution and it was established that they had died because they had stopped moving and their colors had faded [18-21].

RESULTS AND DISCUSSION

Phytochemical Screening

Preliminary phytochemical analysis of hydroalcoholic plant extracts revealed the presence of alkaloids, flavonoids, carbohydrates, steroids and proteins (Table 1).

Anthelmintic activity

The hydroalcoholic extract of the aerial parts of *Andrographis echioides* tested on Indian earthworms *Pheritima posthuma* at 10mg/ml, 20mg/ml, 30mg/ml, 40mg/ml and 50 mg/ml using piperazine citrate as a standard. The study clearly reveals that *Andrographis echioides* hydroalcoholic extract possess moderate anthelmintic properties. But it was found that the effect of the hydroalcoholic extract was not as strong as that of the standard drug piperazine citrate. Table No.2 shows the results of the study. * The experiment was carried out three times and average value was taken.

CONCLUSION

In the study, hydroalcoholic extract of *Andrographis echioides* aerial parts at 10mg/ml, 20mg/ml, 30mg/ml, 40mg/ml and 50mg/ml were compared to the standard drug piperazine citrate for their anthelmintic potential. The study concludes that the hydroalcoholic extract possess moderate anthelmintic properties. It was discovered that the anthelmintic efficacy of the extract was significantly less potent than that of the standard drug piperazine citrate. According to the present study the plant *Andrographis echioides* possess significant anthelmintic properties. We expecting that the further investigation of various extracts of *Andrographis echioides* may be result in high anthelmintic properties compared to standard anthelmintic drugs.

ABSTRACT

Marma comprises an important place in Ayurveda literature. Marma injuries have been mentioned since ancient times in the context of war fares. Now in this changing scenario we need to look at it in a different perspective and in a wider range. Kukundara Marma, a Vaikalyakara Marma structurally categorized under Sandhi Marma[1]. The location is said as on either side of 'Pristavamsha' on 'Jagana Bahirbaghaga', injury to which causes loss of movement and loss of sensation in the lower part of the body[2]. In Ayurveda various modalities like Agnikarma, Vidhakarma etc. has been described for abhighata. in present study 55 years old female patient came with the complain of pain in the low back along with difficulty in movement since 3months, she had history of fall 5days back and heavy weight lifting during daily household work since long time. After thorough clinical assessment she was diagnosed as

Kukundar marma abhighata and she was given Agnikarma for 4 sittings on 3 days gap along with some internal medication and she got relief in pain and movements were improved. So Agnikarma is can be beneficial in Kukundar marma Abhighata.

Keywords: Marma, Ayurveda literature,

INTRODUCTION

Knowledge about Marma is important in surgical procedures like Agni Karma, Ksharakarma and Shastrakarma. It helps to perform these procedures without complication. In case of trauma, it is useful in understanding the possible anatomical structure affected and possible deformities which can be produced. Hence the knowledge about Marma is essential. Kukundara is one of the Vaikalyakara Marma, two in number, present on both sides of the spine, related to the dorsolateral aspect of the pelvic bone and structurally categorized as Sandhi Marma. According to the Susruta Samhita, an injury to the Kukundara marma results in loss of movement and loss of sensation, which requires further emphasis on anatomical, functional and clinical reasons supported by current science[3].

Case

A female age 55 years visited Shalya Tantra OPD of Quadra institute of Ayurveda, Roorkee with complains of pain in low back region associated with difficulty in movements since 3 months. She had history of fall 5 days back and heavy weight lifting during daily house hold works since long time. Onset of pain was sudden in nature along with restricted and difficulty in forward and backward bending of the low back.

Clinical Examination

- Site**-** lumbosacral region
- Pain present radiating towards right lower limb till mid-calf region

According to VAS Scale grade 6

- Difficulty in the movement of lower limb without support
- Sensentions- present
- Gait – Antalgic

Fig no 1: VAS

Diagnostic criteria[4]

- SLR and DSLR - Positive
- Posterior shear test- negative
- Gapping test- positive
- Sacroiliac squish test- positive
- FABER test- positive
- X- Ray L.S spine shows no bony deformity

Plan of treatment

Karma: after taking informed consent from the patient, patients was given prone position. Tender points near sacroiliac joint identified and Agnikarma with panchaloha Shalaka done. Jatyadighrita was applied on the part where agnikarma was performed.

Therapeutic intervention

1. Prasarinyadikashaya 20ml BD with 40 ml Luke warm water (after food)
2. Simhanad Guggulu 2BD (after food)
3. Rasarajeahwarras 1 BD

Study Duration
Total 12 days (Agnikarma done every 3 days gap for 2 weeks total 4 sittings)
Ayurvedic medication given for 15 days.

Assessment Criteria
Clinical assessment of the patient was done on 1st and 12th day of the treatment.

RESULTS

Patient got significant relief after Agni karma as pain subsided and range of movements improved. (Table: 1)

DISCUSSION

Kukundara Marma is categorized under sandhi marma situated on either side of vertebral column (Prushthavamshaubhayataha), on the outer aspect of Gluteal region (Jaganahbahirbhaga), with dimensions of 1/2 angulapramana. It can be understood that Prushthagata Kukundara marma is located in outer aspect of Gluteal region on the both sides of vertebral column. So anatomically this area is related with sandhi as main structure entity and most probable joint is sacroiliac joint. Here in this patient the cause of the pain can be injury and also the long-standing pressure by heavy weight lifting during daily work, this also holds significant on Kukundar marma abhighata as mentioned by Acharya Sushruta. Agnikarma is beneficial in all painfull disorders According to scientist Dr Ven Hanff, the place where heat burns the local tissue metabolism is improved, thus various metabolic and rejuvenating changes takes places at the site of heat burns, and it leads to increase demand of oxygen and nutrients of the tissues at the site of heat burns. It also excretes the unwanted metabolites and toxins. Due to increased local metabolism, the waste products (metabolites) which are produced gets excreted, which normalize the blood circulation thus resulting in reduction in intensity of pain[5].

CONCLUSION

The observation revealed that Agnikarma Chikitsa provided significant relief in the management of symptoms of Kukundara Marma abhighata(injury) along with Ayurvedic medicine such as pain, tenderness, stiffness and restriction of movements. Early diagnosis of Kukunadra marma abhighata will be beneficial for better management and effective results. Diagnostic tool mentioned above needs to be followed forproper diagnosis of Kukundara marma injury. In initial stage of abhighata(injury) Agnikarma therapy is a fast-acting, rapid Action, less time-consuming, easy-to-use, and non-invasive alternative method.

ABSTRACT

In this paper, we investigate the recurrence relation, generating function and exponential recurrence relation of *k*-colored partitions of an integer *m* with the same number of parts. We provide the q-series of *k*-colored partitions using binomial coefficient concept and some applications in various fields.

Keywords: Partition, *k*-colored Partition, Generating Function, Recurrence relation,q-analog, finite difference method.

INTRODUCTION

The idea of k-colored partition is a fundamental topic in combinatorics. The objective is to partition an integer m into a set of parts with distinct colors, often subject to specific constraints such as the number of parts or their sizes. This area of research explores how different coloring schemes can be applied to partition and has various applications in fields like statistical mechanics, number theory, and cryptography. Notably, k-color partitions provide a framework for understanding the symmetries and distribution properties of partitions when additional restrictions such as limiting the number of parts or the maximum number of colors allowed in a partition are imposed. In 1938, Hardy and wright established fundamental principles for the theory of integer partitions. The colored partitions were introduced by Andrew in 1984 and later in Gasper and Rahman. The studies on partition Theory by the above mathematicians contributed to the modern understanding of partition Theory. The concept of 2-color partition

studied by Jorge E.Androws laid the foundation for further research in this area. This idea can be extended to k-colored partitions involve generating all possible copies of an integer partition with respect to r colors. k-colored partitions means permutation of r colors to the partitioned parts. In the study of integer partitions the objective is to partition an integer m into sets of parts with distinct colors subject to specific constraints.

Definition: (k-color Partition)
The *k*-color Partition of an integer mis the combination of copies of integer mwith respect to the corresponding color *k*.
$\binom{m}{b_1, b_2, \cdots b_k} = \frac{m!}{b_1! b_2! \cdots b_k!}$, where $b_1 + b_2 + \cdots + b_r = m$, and *m* is an integer of partition.
We can construct *22* copies of three color partitions of integer 3 with respective to the three colors, namely
3^O, 3^G, 3^Y, 2^O+1^O, 2^O+1^G, 2^O+1^Y, 2^G+1^G, 2^G+1^O, 2^G+1^Y, 2^Y+1^Y, 2^Y+1^O, 2^Y+1^G, $1^O+1^O+1^O$, $1^O+1^O+1^G$, $1^O+1^O+1^Y$, $1^G+1^G+1^G$, $1^G+1^G+1^O$, $1^G+1^G+1^Y$, $1^Y+1^Y+1^Y$, $1^Y+1^Y+1^O$, $1^Y+1^Y+1^G$, $1^O+1^G+1^Y$.

In this notation, orange integers are denoted with the superscript *O*, green integers
with the superscript *G*, and yellow integers with the superscript *Y*. That means, in the *3*-color partition, the integer *3* contains *3* terms with one part, *6* terms with two parts and *10* terms with three parts.
When we extend this idea to *r*-colored partitions, we can construct the separate tables for all color partitions. From all the tables we have considered only the sequences such that the sum of the integer *m* with same number of parts.
We define a sequence notation,

$P_{k,m}(m)$ = number of *k*- colored partition of integer *m* with same number of parts.

The entries form Pascal simplex sequence. So the sequence of *k*-colored partition of integer m with same number of parts satisfies all properties of Pascal simplex sequence.

Recurrence Relation of *k*-colored partition of an integer *m:*
Let$\{a_m\}$ be the sequence of *k*-colored partition of integer *m* with same number of parts, m^{th} term of the sequence is$a_m = \binom{m+(k-1)}{(k-1)} for\ all\ m \geq 1$

Theorem 1.1:
The recurrence relation *ofr*-color partition of integer *m* with same number of parts is
$\sum_{j=0}^{k} (-1)^{k-j} \binom{k}{j} a_{m+j} = 0, m \geq k$
This recurrence relation satisfied by any color partition of integer *m* with same number of parts.

Proof:
The homogeneous linear recurrence relation with constant coefficients is
$a_m = b_1 a_{m-1} + b_2 a_{m-2} + \cdots + b_k a_{m-k}$
The recurrence relation for the sequence $\{a_m\}$is $a_m = a_{m-1} + \binom{m+(k-2)}{(k-2)} for\ all\ m \geq k.$
We construct finite difference table for *k*-colored partition of integer *m* with same number of parts sequence.
We define, $\Delta a_m = a_{m+1} - a_m$ and$\Delta^2 a_m = \Delta(\Delta a_m)$, etc.
The ***k*th difference (Δ^k) is zero**, so the sequence satisfies a ***k*th–order linear recurrence**.

The *k*–colored partition of integer *m* with same number of parts is a ***k*thdegree polynomialsequence,** often called the ***k*–simplex numbers** or ***(k – 1)*th–order binomial coefficients**. It counts the number of multisets of size *k – 1* from a set of *m + 1* element.

Construction of the recurrence

$$\Delta^{k}_{a_m} = \sum_{j=0}^{k} (-1)^{k-j} \binom{k}{j} a_{m+j} = 0$$

Multiply both sides by *−1*:

$$\sum_{j=0}^{k} (-1)^{k-j} \binom{k}{j} a_{m+j} = 0 \, , m \geq k$$

with*(k – 1)* initial conditions.

Illustration

The recurrence relation *of7*-color partition of integer *m* with same number of parts is

$$\sum_{j=0}^{7} (-1)^{7-j} \binom{7}{j} a_{m+j} = 0 \, , m \geq 7$$

with initial conditions $a_1 = 7$, $a_2 = 28$, $a_3 = 84$, $a_4 = 210$, $a_5 = 462$, $a_6 = 924$.

Proof:

Here we construct finite difference table for *7*-color partition of integer *m* with same number of parts sequence,

The 7th difference (Δ^7) is zero, so the sequence satisfies a 7th-order linear recurrence**.**

The *7*-color partition of integer *m* with same number of parts is a 7th-degree polynomial sequence, often called the **7-**simplex numbers or 6th-order binomial coefficients. It counts the number of multisets of size 6 from a set of *m + 1* element.

Construction of the recurrence

$$\Delta^{7}_{a_m} = \sum_{j=0}^{7} (-1)^{7-j} \binom{7}{j} a_{m+j} = 0$$

Multiply both sides by *−1*:

$$\sum_{j=0}^{7} (-1)^{j} \binom{7}{j} a_{m+j} = 0$$

This gives the recurrence is$a_{m+7} - 7a_{m+6} + 21a_{m+5} - 35a_{m+4} + 35a_{m+3} - 21a_{m+2} + 7a_{m+1} - a_m = 0$, with initial conditions $a_1 = 7$, $a_2 = 28$, $a_3 = 84$, $a_4 = 210$, $a_5 = 462$, $a_6 = 924$.

Generating Functions *k*–colored partition:

In the concept of *k*–colored partition of integer *m* with same number of parts we consider two kind of generating functions.

Theorem 2.1:

The **ordinary generating function** of a sequence $\{a_m\}$,where the a_m is m^{th} term of *k*–colored partition of an integer m with same number of parts is

$$G(y) = \sum_{m=0}^{\infty} \binom{m + (k-1)}{(k-1)} y^m = \frac{1}{(1-y)^k}, |y| < 1, k \geq 2.$$

Proof:

We can prove this theorem using a combinatorial approach.

The ordinary generating function of a sequence $\{a_n\}$ is

$$F(y) = \sum_{n=0}^{\infty} a_n y^n$$

The number $\binom{m+(k-1)}{(k-1)}$ counts the number of k–colored partition of integer m with same number of parts to the equation $y_1 + y_2 + y_3 + \ldots + y_m = m$.

We consider only one variable y_i, which takes values0, 1,2,…The generating function for that variable is $1 + y + y^2 + y^3 + \cdots = \frac{1}{1-y}$

That means y^mrepresentation of *1*-color partitions of integer m with same number of parts and Coefficient of y^m is 1 because there is one way to do it.

We have *k*-colors; therefore each color contributes a generating function $\frac{1}{1-y}$.

So the total generating function is $G(y) = \left(\frac{1}{1-y}\right)^k$. This is because when we multiply generating functions, we can sum over all combinations where the exponents of each variable add up to m.

$$G(y) = \left(\frac{1}{1-y}\right)^k = \sum_{m=0}^{\infty} \binom{m+(k-1)}{(k-1)} \; y^m$$

$$G(y) = \frac{1}{(1-y)^k}, |y| < 1, k \geq 2.$$

Theorem 2.2:

The **exponential generating function** of a sequence $\{a_m\}$, where the a_m is m^{th} term of *k*–colored partition of an integer m with same number of parts is

$$E(y) = \sum_{m=0}^{\infty} \binom{m+k}{k} \frac{y}{m!}^m = \frac{e^y y^k}{k!}, for\ k \geq 1$$

Proof:

We derive the **exponential generating function** for the sequence, using **mathematical induction.**

Let us consider

$$P(k): \sum_{m=0}^{\infty} \binom{m+k}{k} \frac{y}{m!}^m = \frac{e^y y^k}{k!}, for\ k \geq 1$$

For initial induction, we can assume k = 1, we get

$$P(1): \sum_{m=0}^{\infty} \binom{m+1}{1} \frac{y}{m!}^m = \frac{e^y y}{1!}$$

$$\binom{1}{1}\frac{y}{1!}^1 + \binom{2}{1}\frac{y}{2!}^2 + \binom{3}{1}\frac{y}{3!}^3 + \cdots = e^y y$$

That is this is true for *k = 1.*

We can assume that P(r)is true, which means

$$P(r): \sum_{m=r}^{\infty} \binom{m}{r} \frac{y}{m!}^m = \frac{e^y y^r}{r!}$$

We want to show that *P(r +1)*is true

$$P(r+1): \sum_{m=r+1}^{\infty} \binom{m}{r+1} \frac{y}{m!}^m = \frac{e^y y^{r+1}}{(r+1)!}$$

$$\sum_{m=r+1}^{\infty} \binom{m}{r+1} \frac{y}{m!}^m = \sum_{m=r+1}^{\infty} \frac{m-r}{r+1} \binom{m}{r} \frac{y^m}{m!}$$

$$= \frac{1}{r+1} \sum_{m=r+1}^{\infty} (m-r) \binom{m}{r} \frac{y^m}{m!}$$

$= \frac{1}{r+1}\sum_{m=r+1}^{\infty}\frac{y^m}{r!(m-r-1)!}$

Let $m = n - r - 1 \Rightarrow n = m + r + 1$,then when n = r + 1,m = 0 and n→∞ ⇒ m → ∞

$$\sum_{m=r+1}^{\infty}\binom{m}{r+1}\frac{y}{m!}^{m} = \frac{e^y y^{r+1}}{(r+1)!}$$

Hence

$$E(y) = \sum_{m=0}^{\infty}\binom{m+k}{k}\frac{y}{m!}^{m} = \frac{e^y y^k}{k!}, for\ k \geq 1$$

q-series representation of k-colored partition:

Theorem 3.1:

The **q-series representation of** *k*–colored partition of an integer m with same number of parts is

$$\binom{m}{k}_q = \prod_{j=1}^{k}\frac{(1-q^{m+k+j})}{(1-q^j)}, m \geq 1$$

Proof:

The **q-analog** of a positive integer m, denoted $[m]_q$, is defined as

$$[m]_q = 1 + q + q^2 + \cdots + q^{m-1} = \frac{1-q^m}{1-q}$$

This reduces to m when q→1. It is the building block for q-factorials.

The q-factorial**,** denoted $[n]_q!$, is the product of q-integers $[m]_q! = [1]_q[2]_q\cdots[m]_q$

That is $[m]_q! = \prod_{j=1}^{r}\frac{(1-q^j)}{(1-q)}$

Its factorial form is $[m]_q! = (1)(1+q)(1+q+q^2)\cdots(1+q+\cdots+q^{m-1})$

Now substitute the q-factorials into the **of** *k*–colored partition of an integer m with same number of parts, we get

$$\binom{m}{k}_q = \frac{[m]_q!}{[k]_q![m-k]_q!}$$

This is the **q-analogof** *k*–colored partition of an integer m with same number of parts.

There is also a more compact version using **q-Pochhammer symbols**

$$\binom{m}{k}_q = \frac{(1-q^m)(1-q^{m-1})(1-q^{m-2})\ldots(1-q^{m-k+1})}{(1-q^k)(1-q^{k-1})(1-q^{k-2})\ldots(1-q)}$$

From this, we can conclude,

$$\binom{m}{k}_q = \prod_{j=1}^{k}\frac{(1-q^{m+k+j})}{(1-q^j)}, m \geq 1$$

This is a **q-analog** of the classical binomial$\binom{m}{k}$, and it **counts k-dimensional subspaces** of an m-dimensional vector space over F_q.

Graphical Representation of r-colored partitions with same number of parts

The classical partition function in number theory involves writing a positive integer n as a sum of positive integers, where order doesn't matter. The r-colored partition problem extends this by allowing each part to have one of r different colors. This adds a new layer of complexity and possibility. This coloring increases the number of possible partitions compared to the uncolored case. Mathematically, the generating function for the number of r-colored partitions of n, denoted $p_k(n)$, is given by When r=1, this reduces to the ordinary partition function p(n), while larger r introduce combinatorial growth as each part may be chosen in multiple ways.Using truncated power series expansions of the generating functions, the values of $p_r(n)$ were computed for all r = 1, 2, …, 20 and n ≤ 200. The results were visualized.

Observations

As r increases, the growth of $p_r(n)$ accelerates dramatically. For instance, $p_1(200)$ is around 10^{12}, whereas $p_{20}(200)$ is enormously larger. When graphed on a logarithmic scale, $p_r(n)$ vs. n exhibits a nearly linear trend for large n, revealing exponential-like growth in partition numbers. Colored partitions form a nexus between combinatorics, q-series, and statistical mechanics, offering a natural extension of the classical partition problem. This concept intersects with modular forms, representation theory, and symmetric functions. In computational number theory, datasets like this one facilitate the exploration of asymptotic patterns and verification of hypotheses regarding partition growth.

Corollary 3.1:

The **q-generating function** of *k*–colored partition of an integer m with same number of parts is

$$G_q(y) = \sum_{n=0}^{\infty} \binom{n+k}{k}_q \quad y^n = \frac{1}{(y;q)_k}, \qquad for\ k \geq 1$$

Where $(a;q)_n=(1-a)(1-aq)\cdots(1-aq^{n-1})$

Corollary 3.2:

The**q-exponential expansion** of *r*–color partition of an integer m with same number of parts is

$$E_q(y) = \sum_{b_1+b_2+\cdots+b_m=m}^{\infty} y^{\sum_{i=1}^{k}(i-1)b_i}, \qquad for\ k \geq 1$$

This sum is over integer compositions $(b_1, b_2,\ldots b_m)$ of m, and the exponent counts the weighted number of inversions or combinatorial statistics like major index**,** area**,** etc.

Graphical Representation of 3-colored partitions

The table of 3 -colored partitions likely displays the number of ways to partition integers into distinct parts, with each part assigned one of three colors. This table can help identify patterns and relationships in combinatorial mathematics.

This is a table of 3-colored partitions, and in this table, the partitions are considered part-wise. For example, 3-colored partition of integer 4 has 3 with one part, 15 with two parts, 18 with three parts, and 15 with four parts, respectively. The leading diagonal entries denote 3-colored partition of integers with the same numerical values and parts, i.e., the partition of m with m parts, and the corresponding bi-diagonal entries denote m+ 1 partitions with m parts, respectively. Based on the table, we observed the following sequences from the diagonal entries. For all m ≥ 1,

$\{P_{3,m}(m)\}$ = {3, 6, 10, 15, 21, 28, 36, 45, 55, 66, ...}
$\{P_{3,m}(m + 1)\}$ = {3, 9, 18, 30, 45, 63, 84, 108, 135, ...}
$\{P_{3,m}(m + 2)\}$ = {3, 15, 36, 66, 105, 153, 210, 255, ...}
$\{P_{3,m}(m + 2)\}$ = {3, 18, 55, 114, 195, 298, 423, 570, ...}

The graphical representation of k-colored partition of an integer m reveals that the partitions follow a bell-shaped curve, indicating that they are normally distributed. This normal distribution pattern allows for a better understanding and statistical analysis of the partition counts, providing insights into the behavior of k-colored partitions.

Applications of the k-colored partitions.

In this section, we focused on a few applications of k-colored partitions, exploring their utility in various contexts.

Lattice Path Interpretation

In Lattice Path Interpretation problems, r-colored partitions are a key concept where parts of size m can take m distinct colors. These partitions help interpret identities in q-series and combinatorics, such as the Rogers-Ramanujan identities, by linking colored parts to specific steps or restrictions in lattice paths. The colors add a layer of

complexity, corresponding to variations in path progression, and enabling deeper analysis of combinatorial structures. In this session we used two coloring schemes in the field of Lattice path interpretation namely, Random Lattice path coloring, Per-part Lattice path coloring.

For example,
We consider the 5-colored partition of an integer 13 with 4 parts, particularly the partition is 13 = 7+3+2+1. The partition is visually represented by a Ferrers diagram, where the lattice path follows the outer boundary from (0,4) to (7,0), and distinct colors can be assigned to the boxes according to specific coloring rules.

Random Lattice path Coloring
In this coloring method we followed the scheme that, each cell in the partition is assigned a color independently, randomly chosen from the available palette.

Here is the random cell-wise coloring version of the partition 13 = 7 + 3 + 2 + 1 with 5 colors applied independently to each square. With the following properties,

It has maximum diversity of colors per diagram, no correlation between adjacent cells or rows and it is useful in simulations and stochastic models.

Per-part Lattice path coloring (row-wise by part size)
In this coloring method all cells in the same part row-wise have the same color and different parts may have different colors. Here is the per-part coloring version with each row corresponding to a part of the partition 7, 3, 2, 1 is given a single distinct color. With the following properties, In this coloring each row is uniform; allowing clear structural analysis and it is useful in representation of restricted partitions or weighted diagrams. Also we draw paths from (0,0) to (3,2) using 3 Red color paths (R) and 2 Green color paths (G) . Each path corresponds to a binary string with 3 R's (0's) and 2 G's (1's), same as above. We assign area = number of full squares under the path. Now we find all partitions that fit in a 3×2 box (i.e., ≤ 3 rows, each ≤ 2).

From this observation, we get

$$\binom{5}{3}_q = 1 + q + 2q^2 + 2q^3 + 2q^4 + q^5 + q^6$$

The q-binomial coefficient $\binom{m}{k}_q$, a q-analog of *k*–colored partition of an integer *m* with same number of parts, plays a vital role in combinatorics and enumeration by encoding additional structure through powers of q. It arises in various interpretations, each offering rich combinatorial meaning. Algebraically, it is defined as a ratio of q-factorials and generalizes the binomial coefficient by introducing a weighting parameter q. Combinatorially, $\binom{m}{k}_q$ counts the number of k-dimensional subspaces of an m-dimensional vector space over a finite field Fq, hence known as the Gaussian coefficient. In binary word enumeration, it counts the number of sequences of *m* bits with exactly k ones, weighted by the number of inversions (i.e., pairs where 1 precedes 0). It also arises in lattice path enumeration from (0,0)to (k,m−k), where the power of q tracks the area under the path. Alternatively, it is the generating function for the number of integer partitions that fit in a k×(m−k) rectangle, with q marking the number of boxes. These interpretations unify under the framework of q-analogs, linking the q-binomial to areas such as partition theory, symmetric functions, representation theory, and coding theory, making it a central object in algebraic and enumerative combinatorics. The same coloring scheme we can apply in few more application areas like Hard Sphere Model, Hard Rods and Lattice Gases also.

CONCLUSION

In this work the tables of k-coloredpartitions of integer m with same number of parts and the table of 3-colored partitions of integer m are constructed. From the entries of the table, recurrence relations, generating functions, q-series expansion also discussed and mainly focused the applications of k-colored partitions of integer m with same number of parts with q-series. Also we investigate some applications of colored partitions in various fields. This concept can be extended for bi-diagonal entry layers of *k*-colored partitions.

ABSTRACT

In India, Buses are still the main mode of public transportation for many low-income and middle-income people to travel for their personal and professional purposes. Nowadays, role of private bus operators is becoming important and essential to support the entire population as well as the transportation industry. Psychological burnout means the state of psychological and physical fatigue that shows the effect of work stress on individual and negatively affects person's attitudes towards work. More than 50 percent of occupational illnesses or diseases are associated with their psychological burnout which influences workers well-being and also organisations' success. This study is focusing on studying the working conditions and its influences on private bus drivers' psychological burnout as well as health outcomes in Northern Tamil Nadu. Research study found that the working conditions related factors are related to bus drivers' psychological burnout and job satisfaction levels through statistical tools like Multinominal Logistic Regression, Regression analysis and chi square test. This research findings are confirming that

Less rest/break at work, Troublesome passenger, Bad road condition, Heat and Sweating and Improper healthy and nutritious food intake are highly influencing the Level of Psychological burnout of private bus drivers in selected research areas. More than ninety percent of private bus drivers have no medical and life insurance and also have no regular health checkups to them to know their health status. This research paper proposes the suitable measures to policymakers and private transport operators on managing psychological burnout among bus drivers to make them safe and happy and also to make every passenger's journey, a safe and happy journey.

Keywords: Bus drivers, Psychological burnout, Working condition, Job safety, Job satisfaction, Health Outcomes.

INTRODUCTION

Bus drivers are the main pillars of the bus transportation service to make safe and happy journey to the passengers. Psychological burnout is one of the most severe incidents to be encountered at work. It is defined as a group of symptoms of a sense of dissatisfaction, depersonalization, exhaustion of emotional energy and nervous stress with one's personal achievement in one's professional field. (Goddard and Goddard, 2006). Individuals whose jobs require considerable contact with others, like drivers, health-care personnel and teachers, may have a high likelihood of experiencing Psychological burnout - emotional exhaustion (Chaukos *et al* ., 2017). Previous research reviews have shown that Psychological burnout - emotional exhaustion had negative effects both on employer and employees (Bakker, Westman, and Schaufeli, 2007). In general, psychological burnout may negatively affect employees' health (Chen and Chen, 2012), job satisfaction, job performance, and organizational commitment (Singh, Goolsby, and Rhoads, 1994). Ismail, Abdullah, and Abdullah (2015) High temperature can also affect the driver's behavioral response. There is a significant positive correlation between thermal comfort and the driving ability of bus drivers. Peters, Susan and Grogan, *et al* . (2021) M.R Winkler (2017) Workers with more control over their schedules and shifts are feeling higher health issues than those with little control. Also, Brauner. *et al* . (2019) Less sleeping hours (<6 h per day) and Long work hours are greatly associating with metabolic and cardiovascular diagnoses. Thus it is clear that work scheduling and work hours are major determinants of drivers' health outcomes. With the help of latest technology, the transport operators should make proper work scheduling and shifts to their drivers in order to reduce the impacts over drivers' fatigue, health and well-being. Sekkay F (2019) Musculoskeletal injuries and accidents are happening a lot because of bus drivers' physical environment and external factors like weather or road conditions.

THEORETICAL BACKGROUND

PSYCHOLOGICAL BURNOUT AND HEALTH OUTCOMES

Psychological burnout is one of the most severe incidents to be encountered at work. It is defined as a group of symptoms of a sense of dissatisfaction, depersonalization, exhaustion of emotional energy and nervous stress with one's personal achievement in one's professional field. (Goddard, 2006). Emotional exhaustion can result in reduced job satisfaction (Shanafelt *et al* ., 2015), inappropriate behavior with coworkers and customers (Kim, 2008), and may lead employees to quit their jobs (Skaalvik and Skaalvik, 2016). In general, psychological burnout may negatively affect employees' health (Chen and Chen, 2012), job satisfaction, job performance, and organizational commitment (Singh, Goolsby, and Rhoads, 1994). Bradley, Grossman, *et al* . (2016) for any professional workers, their work and working conditions become crucial determinant of their safety, health and well being. Useche, Cendaleset.al.(2018) Working conditions of any work are characterized by its workloads, work schedules, work target time, mental alertness, job control, customer confrontations and standard risks at work. The working conditions are having their respective physical and psychological hazards. Raharjo *et al* (2021).Income and working hours are crucial factors influencing psychological burnout among bus drivers. Common reasons of bus drivers' Psychological burnout are

personal and family commitments, financial condition, weather conditions, Road condition, vehicle condition, threat of accident, troublesome passengers and other drivers, relationship with peer group and management, poor work life balance, occupational illness, and others. Anna Anund (2017), studied Israel urban drivers' 12 month of work related health outcomes and found that Low back pain and neck pain are their highly influenced health issues (Figure No. 1). Figure No. 1 12 Month Prevalence of work related Musculoskeletal pain by body region in Professional urban bus drivers

REVIEW OF LITERATURE

Chayuth Tangwiwat, Pornchai Sithisarankul (2024), In Bangkok, The shifting social and environmental contexts are contributing to an annual rise in work-related stress and mental health issues to the bus drivers nowadays. Due to their professions and the hazardous working conditions that can lead to stress at work and mental health issues, bus drivers are especially susceptible to these issues. Major Factors associated with psychological burnout were high physical job demands, social support, working hours and work hazards. Organizations should encourage better policies regarding job-related stress and mental health issues of Bangkok Bus Drivers. Durgamani, Suresh and Sethuraman (2022), In Thanjavur district, private bus drivers and conductors had exposed more towards psychological burnout because of conflicting demands such as safeguarding passengers, meeting out tight work scheduling, balancing professional and personal life, irregular day-off, dealing troublesome passengers, obeying traffic rules, making more profit to private bus operators, dealing unexpected accidents, etc. Their major stressor was Job security. They suffered from piles since they are exposed to long hours of travel and engine heat. They used to spend time on using smart phones during free time for getting relieved from psychological burnout. Researcher had found there is significant difference between work experience and stressors, job requirements and psychological problems and age and work hazards. Dev, Samrat and Gangopadhyay, Somnth. (2022). this study is aimed on evaluating Kolkata city bus drivers' occupational psychological burnout factors and their effects among their social and professional life. WHO's "Quality of Life Questionnaire" and Occupational Stress Index (OSI) had used for this study. Results indicated that bus drivers had stressful work environments so they had poor quality of life (social and professional). This had direct impact with drivers' safety, comfort and overall productivity. Sun, X., and Dong, J. (2022)Study aimed on evaluating the drivers' physiology and reaction because of high-temperature environments impact of and offering better driver occupational health management techniques.

Study results found that reaction ability, physiological strain index (PSI), heart rate and body temperature were significantly different among varied temperatures at work. PSI had positive correlation with reaction ability. Bus drivers felt stressed because of High-temperature environments. This also affected them physiologically and their behaviour changed. Peters, Susan and Grogan, *et al* . (2021),this study aimed at determining the crucial working conditions related factors contributing to professional bus drivers' safety, health, and well-being with qualitative approach. Long work hours and short sleep duration (<6 hours/ day) were associated with various health conditions like metabolic and cardiovascular diagnoses. Drivers' common health related concerns were fatigue, psychological burnout, and never-ending health conditions. Their short break rest time, food intake and inability to exercise are causing poor health outcomes to the drivers. This paper also found that determinants of health and well-being outcomes i.e working conditions causing poor safety, health, and well-being outcomes are very difficult to ascertain. Raharjo, T., Musyarofah, S., and Maghfiroh, A. (2021). During COVID- 19 pandemic period, this study had carried out cross sectional study with Chi- square statistical test to decide the bus drivers' psychological burnout in relation to their income and work period. It had found that there was relationship between income and work-length factors in relation to psychological burnout among bus drivers at Bahurekso, Kendal terminal. Tu, Zhihao and He, Jingwen *.et al* (2021). This study investigated the relationship between driver-passenger communicative stress and psychological distress among bus drivers and also the impact of their psychological burnout. Cynicism, emotional exhaustion and Driver-passenger communicative stress had positive association with bus drivers' psychological distress. Communicative stress was affecting Chinese bus drivers' psychological distress and Psychological burnout had become mediator of this relationship.

RESEARCH OBJECTIVES

Following are the major objectives of this research

1. To study the socio-economic conditions and lifestyle of the private bus drivers in Northern Tamil Nadu.
2. To understand the working conditions and its influences on the private bus drivers' Psychological burnout and Job satisfaction in the selected study area.
3. To find out the various health outcomes of private bus drivers from their working conditions and Psychological burnout.
4. To give suitable suggestions to improve the working conditions and Job satisfaction, Job safety and to reduce the psychological burnout of selected transport drivers.

Hypothesis of the Study

This research study has framed the following hypothesis related with the research objectives.

H1: There is significant difference in level of psychological burnout among private bus drivers due to their working conditions related factors

H2: There is significant difference in Job satisfaction among private bus drivers due to their working conditions related factors

METHODOLOGY

Proper research work depends on its data collection of both primary and secondary data. Here Researcher collected its primary data through issuing structured questionnaire among private bus drivers of Northern Tamil Nadu. Also we gathered research oriented secondary data with the help of previous research papers, news paper articles, reports, websites, etc. Research study's population covers Private town bus drivers of Northern Tamil Nadu. Research study area includes Private town bus drivers of Villupuram, Cuddalore, Vellore, Tiruvannamalai, Kancheepuram and Thiruvallur Regions. It has 1350 drivers in northern Tamil Nadu. From the finite population size of 1350, sample size is measured as 300 in Northern Tamil Nadu through following formula Simple random sampling method was used to select the sample. Collected data is analysed and interpreted through Percentage analysis, Chi Square Test and Regression Analysis. Research findings and conclusion are proposed through the outcomes of this data analysis and interpretation.

Stepwise Regression Analysis

Below table no. 1 shows the relationship between level of psychological burnout and working condition with the help of Stepwise regression model. This model was applied with factors of working condition with respect to work psychological burnout. Here Less / Break at work, Heat and Sweating and Improper healthy and nutritious food intake are playing significant role in level of psychological burnout of private bus drivers at 5 percent level of significance. Below table No. 2 shows the relationship between Job satisfaction and working condition with the help of Stepwise regression model. This model was applied with factors of working condition with respect to Job satisfaction. Here Proper Ventilation, Poor Sleeping pattern, Bad Road Condition, Improper Healthy And Nutritious Food intake and Unsafe work Lifestyle are playing significant role in level of Job satisfaction of private bus drivers at 5 percent level of significance

Multinominal Logistic Regression

This regression model was used when both dependent and independent variables are of continous scale. From the below table No. 3, it is found that in this model, the dependent variable is a category variable with three continous variables used in this study. So we have used Multinominal logistic regression. Here, the level of stress is dependent variable with three categories namely Low, Moderate and High Stress. Above Model fitting information shows that the final model is significant which means that final model is improved than basic model. Pseudo R-Square (table no. 4). From the below table, the independent variable namely experience, working hours and sleeping hours explain 10

% of level of stress since the 'Nagelkerke pseudo R square' value is 0.10. The below table No. 5 Parameter estimates Model compares the Low stress, Moderate stress and High stress. The Multinominal regression keeps Low stress as a base / reference Model. Considering Driving hours, odd ratios are greater than 1, explaining that more chances of getting stress to bus drivers at work. In the below table model, coefficient of 'Driving hours per day' is 0.57 which means that driving hours (0.57), stress is increased and the chance of 1.058 times more stress than 'Low stress group'. Considering Experience of bus drivers, the coefficient value of 0.52 (Experience) denotes for every 1 year of experience, the stress level is increased by 0.052 and the chances are 1.053 times more of stress than 'Low stress group' at 10 % significance level. Hence, the coefficient of driving hours, sleeping hours and experience are 0.499, 0.249 and 0.109 with chances are 1.648, 1.283 and 1.115 times greater than Low stress Category. At 1 % significant level, driving hours, sleeping hours and experience are highly influenced the level of stress of bus drivers at work. Results of Multinominal logistic regression found that driving hours, sleeping hours and experience are highly increasing the stress level of bus drivers. When driving hours, sleeping hours and experience are increasing, the stress level of bus drivers is increasing. From the below table no. 6, chi square values of various variables related to working condition with respect to level of psychological burnout are calculated. Since the p-value < 0.05, we can conclude that there is significant relationship between Level of Psychological burnout and Troublesome passenger, there is significant relationship between Level of Psychological burnout and less rest / break at work and also there is significant relationship between Level of Psychological burnout and Bad road condition.

Hence the working conditions related factors like Less rest / break at work, Troublesome passenger and Bad road condition are highly influencing the Level of Psychological burnout of private bus drivers. Since p - value > 0.05, there is no significant relationship between level of psychological burnout and time pressure and there is no significant relationship between level of psychological burnout and Driving for long hours or distance. From the below table no. 7, chi square values of various variables related to working condition to with respect to job satisfaction are calculated. Since the p-value < 0.05, we can conclude that there is significant relationship between job satisfaction and Troublesome passenger, there is significant relationship between job satisfaction and Time Pressure, there is significant relationship between job satisfaction and Driving for long hours or distance and also there is significant relationship between job satisfaction and Bad road condition. Hence the working conditions related factors like Time Pressure, Driving for long hours or distance, Troublesome passenger and Bad road condition are highly influencing the job satisfaction of private bus drivers. Since p - value > 0.05, there is no significant relationship between job satisfaction and less rest / break at work. The below table no. 8 shows that the nearly 90 per cent of private bus drivers had no life and medical insurance in Northern Tamil Nadu. Like government bus drivers, private bus operators should provide free medical and life insurance to all the drivers at work and their life has to be insured for safeguarding themselves from any unexpected sufferings. Also more than 90 per cent of bus drivers had no proper and regular medical checkups on their work to check their health status. The below table no.9 explains that majority of the private bus drivers had suffered from back pain and full body pain in this study areas. Hence the private bus drivers should take necessary measures to get rid of back pain and full body pain through proper nutritious food intake, simple stretches or exercises, proper job ergonomics – seating arrangements and postures, sufficient sleep and breaks and others.

RESULTS AND DISCUSSION

Regression analysis (Table No. 1) has found that study variables like Less / Break at work, Heat and Sweating and Improper healthy and nutritious food intake are playing significant role in level of psychological burnout of private bus drivers. Also, (Table No. 2) Study variables like Proper Ventilation, Poor Sleeping pattern, Bad Road Condition, Improper Healthy And Nutritious Food intake and Unsafe work Lifestyle are playing significant role in level of Job satisfaction. Results of Multinominal logistic regression (Table No.5) found that driving hours, sleeping hours and experience are highly increasing the stress level of bus drivers. When driving hours, sleeping hours and experience are increasing, the stress level of bus drivers is increasing. Results of Chi square analysis (Table No. 6) pertaining to psychological burnout has shown that bus drivers' working conditions related factors like Less rest / break at work,

Troublesome passenger and Bad road condition are highly influencing the Level of Psychological burnout of private bus drivers. Also, there is no significant relationship between level of psychological burnout and time pressure and there is no significant relationship between level of psychological burnout and Driving for long hours or distance. Results of Chi square analysis (Table No. 7) pertaining to job satisfaction has shown that bus drivers' working conditions related factors like Time Pressure, Driving for long hours or distance, Troublesome passenger and Bad road condition are highly influencing the job satisfaction of private bus drivers. Also there is no significant relationship between job satisfaction and less rest / break at work. In Northern Tamilnadu, it has found that more than 90 per cent of bus drivers (Table No. 8) had no proper and regular medical checkups on their work to check their health status. It's a crucial challenge to all bus drivers of private operators. Private bus drivers are suffering mostly from back pain and full body pain in relation to their health outcomes (Table No. 9). This study has clearly found the implications regarding the bus drivers' job psychological burnout and working conditions. We are recommending / suggesting the policy makers and private bus operators to take care of bus drivers on following measures

- Provide proper breaks or rests between the rides for getting relax.
- Offer training on passenger relations and handling politely to handle troublesome passengers.
- Offer healthy and nutritious meals and snacks to bus drivers to make them healthy and active.
- Feel them safe by offering better safety tools and training on safe driving behaviour.
- Policy makers and private bus operators should provide free medical and life insurance to all the drivers at work and their life has to be insured for safeguarding themselves from any unexpected sufferings.
- Private bus drivers should take necessary measures to get rid of back pain and full body pain through proper nutritious food intake, simple stretches or exercises, proper job ergonomics – seating arrangements and postures, sufficient sleep and breaks and others.

This research study has certain limitations i.e. it is confined with private bus drivers of certain routes only. Also, some of the drivers were not provided information with clear and confident since they are fearful on disclosing their opinions of their workplace.

CONCLUSION

In Northern Tamil Nadu, private bus drivers are facing challenges related to their working conditions. They have conflicting demands such as safeguarding passengers, meeting out tight work scheduling, balancing professional and personal life, irregular day-off, dealing troublesome passengers, obeying traffic rules, making more profit to private bus operators, dealing unexpected accidents, etc. Research study found that the working conditions related factors are related to bus drivers' job psychological burnout and satisfaction levels in Northern Tamil Nadu. Research findings are that working conditions related factors like Less rest / break at work, Troublesome passenger and Bad road condition are highly influencing the Level of Psychological burnout of private bus drivers and also driving hours, sleeping hours and experience are highly increasing the stress level of bus drivers. When driving hours, sleeping hours and experience are increasing, the stress level of bus drivers is increasing. Hence, the private bus transport organisations should take care of the bus drivers' working conditions associated factors. If they have better working environment, they feel more satisfied and less stressed. Also, More than ninety percent of private bus drivers have no medical and life insurance and also have no regular health checkups to them to know their health status. Thus the policy makers and private bus operators should implement our research suggestions and should insure all the bus drivers to safeguard themselves and make the safe and happy journey to both bus drivers and passengers.

ABSTRACT

Wound healing has historically posed significant challenges, with injuries and infections often resulting in serious complications or even death. Although surgical techniques and medical technologies have advanced considerably, effective wound care continues to be an area of active investigation. This study assesses the therapeutic potential of *Kala Malham*, a classical Ayurvedic formulation, in the management of *DustaVrana* (chronic wounds). Emphasis is placed on its ability to accelerate healing, reduce pain, and minimize scarring. Clinical findings indicate that *Kala Malham* effectively promotes granulation tissue formation, decreases wound size, and supports rapid recovery. Its affordability and natural composition position it as a promising alternative in wound care. By integrating traditional Ayurvedic knowledge with modern clinical practices, this study underscores the continued relevance and applicability of *Kala Malham* in contemporary wound management. The primary objective is to evaluate its efficacy in the healing of *DustaVrana*.

Keywords: Kala Malham, Dusta Vrana, Chronic Wounds, Ayurvedic Treatment, Wound

INTRODUCTION

Wound healing has been a pivotal concern throughout human history, as untreated or infected injuries often posed life-threatening risks. Even with remarkable progress in surgical methods and medical technology, achieving effective and holistic wound management continues to be a complex and dynamic area of healthcare. Modern surgeons aim for faster recovery, reduced scarring, and comprehensive pain control. Ancient Indian scriptures, including the Vedas, have long offered insights into wound treatment—evident in episodes like the *DevasuraSangram*. Sushruta, revered as the pioneer of Indian surgery, laid down systematic classifications of wounds and established foundational principles for their care. His recommendations—such as primary suturing of clean wounds and management of abdominal injuries—exhibit a surprisingly contemporary understanding of surgical practices. In an age driven by high expectations for instant medical outcomes, modern interventions often meet these demands, yet can sometimes result in adverse side effects—summarized by the saying, "healing one part while harming another." Ayurveda, with its roots in the *Atharvaveda*, offers a holistic and side-effect-minimized alternative, focusing on both healing and disease prevention for sustained health. This blend of time-tested Ayurvedic principles and modern advancements emphasizes the continued need to harmonize ancient wisdom with technological progress for comprehensive and effective wound management.

Patient Information

The current study involved 30 patients diagnosed with *DustaVrana* (chronic wounds), who were randomly allocated into two groups, each consisting of 15 individuals. Selection of patients was carried out based on specific criteria:

Inclusion Criteria: Individuals between the ages of 18 and 60 years presenting with *DustaVrana* accompanied by classical *Lakshanas* (symptoms) were included in the study. Patients were chosen regardless of gender, religion, occupation, or socio-economic background.

Exclusion Criteria: Patients younger than 18 years or older than 60 years, as well as those diagnosed with conditions such as malignancy, syphilis, tuberculosis, leprosy, HIV, HBsAg positivity, VDRL positivity, burns, uncontrolled diabetes mellitus, osteomyelitis, or anaemia, were excluded from the study.

Assessment Criteria

Subjective Criteria Table 1. (Subjective Criteria)

- Pain
- Burning sensation
- Itching Sensation
- Size of Wound
- Smell

Objective Criteria

Discharge Table 2. (Objective Criteria – Discharge)
Colour Table 2. (Objective Criteria – Colour and Granulation Tissue)
Granulation Tissue Table 2. (Objective Criteria – Colour and Granulation Tissue)

Investigations

Blood Tests ----Complete Blood Count (CBC), Random Blood Sugar (RBS) , HIV, HBsAg , VDRL
Urine Tests ---Routine and Microscopic Examination
Sputum (if required) ---Acid-Fast Bacillus (AFB) test
Pus (if required) --- Culture for microbiological analysis
Biopsy (if required) -- Tissue biopsy for microbiological examination
Radiology --- Imaging studies as per clinical requirement

MATERIALS AND METHODS

Drug Preparation

The ingredients — *Gandhabiroja, Sindoor, Tilataila*, and *Karpur* — were sourced from the market and the Malham (ointment) was prepared at P.I.A. Pharmacy, Limda.

Raw Materials and Actions

Gandhabiroja (1.6 kg): Kapha-Vata shamak, Jantughna, Raktotkleshak, Vranashodhaka, etc.
Sindoor (200 gm): Vranaropaka, Kushthagna, Kandughna, Visarpahara.
Tilataila (600 gm): Vedanasthapan, Vatahara, Vranaropana, Snehan.
Karpur (80 mg): Vedanasthapan, Tridoshahara, Pachana, Kandughna.

Preparation Process

- Tilataila was heated in a vessel.
- Sindoor was added and stirred carefully to prevent overflow.
- Heating continued on *Manda Agni* until Sindoor turned black.
- The mixture was tested in water for proper consistency:
- If dispersed: *Apakva* (undercooked).
- If sank instantly: *Atipakva* (overcooked).
- Ideal Malham forms a soft pill in water.
- Once suitable, the Malham was reheated, and Gandhabiroja was added and mixed.
- After cooling, Karpur was added.
- The final Malham was stored in containers for use.

Study Design: An Open Randomized Clinical Comparative Study
Grouping of Cases: The present study was conducted on 30 cases of *DustaVrana* (chronic wound). These cases were randomly divided into two groups, with 15 patients in each group:
Group A (Control Group): Treated with Betadine Ointment.
Group B (Trial Group): Treated with *Kala Malham* for dressing
Drug Dosage: The drug dosage was determined based on the requirement of each case.
Sample Size: Initially, 32 patients were enrolled in the study. However, two patients dropped out, resulting in a final sample size of 30 patients.

Intervention

The patients were treated with the local application of *Kala Malham* once daily until complete epithelialization or for a maximum duration of 30 days.

Materials Used

1. *Kala Malham*
2. Distilled water
3. Draping sheet
4. Sterile gloves
5. Roller bandage
6. Sterile gauze piece

PROCEDURE

The treatment protocol was structured into three primary stages

Poorva Karma (Pre-procedure)

Patients were briefed about the procedure, and informed consent was obtained. Depending on the location of the wound, appropriate positioning was ensured. This was followed by thorough wound cleansing and debridement using distilled water.

Pradhana Karma (Main Procedure)

Maintaining strict aseptic conditions, either *Kala Malham* or Betadine was topically applied to the wound. The area was then covered with sterile gauze and secured with a proper dressing.

Paschat Karma (Post-procedure)

Patients were advised regarding *Pathya* and *Apathya* (suitable diet and lifestyle practices), instructed to maintain cleanliness and dryness of the wound site, and scheduled for regular follow-up visits to monitor the healing process.

Observations and Follow-Up

Dressing Frequency: *Kala Malham* was applied once daily.

Treatment Duration: Therapy continued until complete epithelialization was observed or for a maximum period of 30 days, whichever was earlier.

Outcome Evaluation: Healing progress was evaluated based on the speed of epithelialization, reduction in wound dimensions, and overall improvement in wound healing parameters.

OBSERVATION

Effect on Pain

In this study, a noticeable reduction in pain was observed in both groups after treatment. The average pain score in the control group (Betadine) decreased from 4.43 to 1.27, while in the trial group (Kala Malham), it dropped from 4.57 to 1.77—both indicating statistically significant outcomes. By the end of the 30-day treatment period, participants in both groups experienced substantial pain relief. The analgesic and anti-inflammatory properties of Kala Malham, particularly due to its α-Pinene content, played a crucial role in alleviating pain and inflammation.

Effect on Burning Sensation

Post-treatment assessments showed that the average burning sensation score reduced from 3.03 to 2.37 in the control group and from 4.17 to 2.33 in the trial group. The reduction was significant, with complete relief from burning sensation observed during follow-up in both groups. The faster recovery in the trial group highlights the effectiveness of Kala Malham, whose anti-inflammatory constituents contributed to this improvement.

Effect on Itching

The itching scores decreased notably—from 3.07 to 2.07 in the control group, and from 3.63 to 2.47 in the trial group. This improvement was significant, and follow-up visits revealed complete relief from itching in both groups. The presence of Terpinolene in Kala Malham, known for its anti-fungal and anti-bacterial properties, was instrumental in relieving itching. Additionally, Ayurvedic ingredients such as Sindoor and Karpur, known for their Kandughna (anti-pruritic) effects, supported the reduction.

Effect on Smell

The foul odor associated with the wounds significantly reduced in both groups— from 4.13 to 1.83 in the control group and from 4.40 to 2.33 in the trial group. By the time of follow-up, unpleasant smells were absent in both

groups. This improvement is attributed to the anti-infective and anti-inflammatory actions of Kala Malham. In Ayurvedic texts, Karpur is described as DurgandhaNashaka (deodorizing), aligning with the observed outcomes.

Effect on Wound Size

There was a marked reduction in wound size following treatment. The mean score decreased from 5.00 to 1.07 in the control group and from 5.00 to 1.43 in the trial group—both changes being significant. Wound contraction was influenced by wound size and the antimicrobial activity of α- and β-Pinene in Kala Malham, which accelerated contraction and tissue repair.

Effect on Serous Discharge

Post-treatment, the serous discharge score reduced from 3.60 to 1.87 in the control group and from 3.97 to 1.93 in the trial group. These reductions were significant, indicating improved wound condition in both sets of patients.

Effect on Purulent Discharge

A considerable decrease in purulent discharge was also noted. The average score declined from 4.33 to 1.93 in the control group and from 4.70 to 2.27 in the trial group, with statistically significant results.

Effect on Slough Tissue

After therapy, the mean slough tissue score dropped from 4.43 to 1.53 in the control group and from 4.57 to 2.00 in the trial group. By the end of the first week, slough had largely resolved in patients treated with Kala Malham, with simultaneous granulation. The reduction in bacterial load contributed to this outcome. The antimicrobial activity of α- and β-Pinene, along with Ayurvedic agents like GandhaBiroja and TilaTaila, known for VranaShodhana (wound cleansing), played a significant role.

Effect on Wound Color

Wound color scores improved significantly—dropping from 4.57 to 1.47 in the control group and from 5.00 to 1.60 in the trial group. Kala Malham facilitated granulation and epithelialization, leading to the transition in wound coloration from Shwetarakta (reddish-white) to TwakSavarna (skin-toned). According to Ayurveda, its TwakPrasadana (skin nourishing) quality enhances this effect.

Effect on Granulation Tissue

Improvement in granulation tissue was significant in both groups, with scores decreasing from 4.40 to 1.37 in the control group and from 4.90 to 1.93 in the trial group. Notably, the rate of wound healing was faster in the Kala Malham group (1.23 cm^2/day) compared to the Betadine group (0.83 cm^2/day). This enhanced healing is attributed to the presence of bioactive compounds such as Limonene, Carene, α-Terpinene, and β-Pinene, which possess antioxidant, antimicrobial, and tissue-repairing properties.

.

Overall Effects Discussion

Significant Effects of Group A and Group B

Group A (Betadine ointment) showed significant results after treatment and follow-up, but Group B (Kala Malham) had superior outcomes. Statistical analysis demonstrated that Group B had a higher reduction in pain (72% vs. 66% in Group A), burning sensation (88% vs. 79% in Group A), and itching (77% vs. 74% in Group A). The size of the ulcer was reduced by 63% in both groups, but the color and granulation tissue showed more improvement in Group B.

Discussion on Probable Mode of Action

To achieve effective healing, it is crucial to eliminate local contaminants or debride the Vrana (wound) site. The Sushruta Samhita clearly mentions drugs for Shodhana (cleansing) and Ropana (healing) of Vrana. In cases of Kapha-Vata vranas, Ropanataila (healing oil) prepared with Ropanadravya (healing substances) is traditionally used. A thorough examination of Vrana reveals that treating deranged doshas (body humors) requires a varied approach, as

no single drug is universally effective. Hence, multiple drugs with different properties are categorized as Vrana Shodhaka (wound cleansers) and VranaRopaka (wound healers) in Vrana management. Delayed wound healing often results from contamination, infection, discharge, slough formation, and reduced local immunity. Upon analyzing Kala Malham, it is deduced that the formulation, characterized by its Tikta Rasa (bitter taste), includes Gandhabirija, Sindoor, Karpoora, and Tilataila. These components possess VranaShodhana, VranaRopana, Pootihara, VedanaSthapana, and Tridoshagna properties, directly facilitating Vrana healing.

Chemical Components in Gandha Biroja

1. **Δ 3-Carene:** Analgesic, tissue repair, pain management, and promotes wound healing.
2. **α-Pinene, β-Pinene:** Anti-microbial, anti-inflammatory, anti-bacterial, controls further spread, controlled slough, and discharge.
3. **Terpinolene and Limonene:** Anti-fungal, anti-bacterial, anti-oxidant, anti-inflammatory, reduces itching, tissue repair, and promotes wound size reduction.
4. **Camphene:** Anti-nociceptive activities, anti-oxidant, analgesic, reduces pain, foul smell, and promotes wound healing.
5. **Tannin:** Fibroblast proliferation, healthy scar formation.
6. **Sugar:** Energy supplement action, promotes wound healing.
7. Sesamolinol, γ-tocopherol in sesame oil acts as an anti-oxidant and provides better results in tissue injury.

In conclusion, all the drugs used in the clinical trials contribute to wound cleansing. This may be the reason Kala Malham has shown significant cleansing effects on patients with DustaVrana, a significant finding.

CONCLUSION

Control Group

Among the subjective criteria, burning sensation and itching were markedly reduced, pain was considerably reduced, and smell was slightly reduced. Among the objective criteria, discharge, slough, granulation tissue, and color were significantly reduced, while the size of the ulcer was slightly reduced. In this group, the ulcer healed completely in 8 patients, and the remaining 7 patients showed remarkable improvement.

Trial Group

The treatment with Kala Malham showed faster Shodhana and Ropana effects in DustaVrana. Among the subjective criteria, pain, burning, itching sensation, and smell were significantly reduced. Among the objective criteria, discharge, slough, granulation tissue, color, and size of the wound were significantly reduced. In this group, the ulcer healed completely in 14 patients, and 1 patient showed marked improvement.

Table 1: (Subjective Criteria)

	Grading Description
Pain	• Grade – 0 No pain • Grade – 1 Mild pain • Grade – 2 Moderate pain • Grade – 3 Severe pain
Burning Sensation	• Grade – 0 Absent • Grade – 1 Present
Itching Sensation	• Grade – 0 Absent • Grade – 1 Present
Size of Wound	• The direct area of the wound size is measured and analyzed.
Smell	• Grade – 0 No smell • Grade – 1 Minimum bad smell • Grade – 2 Moderate bad smell • Grade – 3 Unpleasant but tolerable smell • Grade – 4 Foul smell which is tolerable

Table 2: (Objective Criteria – Discharge)

	Serous Grading Discharge	**Purulent Discharge**	**Slough Tissue**
Discharge	Grade – 0 No discharge	No discharge	No slough tissue
	Grade – 1 < 2 ml	< 2 ml	Up to 30% area covered with slough
	Grade – 2 < 5 ml	< 5 ml	31 to 60% area covered with slough
	Grade – 3 > 5 ml	> 5 ml	More than 60% area covered with slough

Table 3: (Objective Criteria – Colour and Granulation Tissue)

Colour	• Grade – 0 Healed wound / Equivalent to skin colour • Grade – 1 Healing wound / Equivalent to brownish-white • Grade – 2 Cleaned wound / Equivalent to reddish-white • Grade – 3 Contaminated or soiled wound / Equivalent to congested reddish-black
Granulation tissue	• Grade – 0 Healthy granulation without slough • Grade – 1 Moderate granulation with slough • Grade – 2 Unhealthy granulation with slough • Grade – 3 Granulation tissue absent

ABSTRACT

Resource allocation is one of the major issues faced by hospital management due to the limited availability of resources. Correctly identifying mortality levels of patients can aid in effective allocation of resources to patients in need of facilities. This work presents an ensemble based modeling technique for effective mortality prediction in ICU patients. The proposed architecture is composed of two major components; the semi supervised grouping component, and the ensemble model for mortality prediction. The base data extensively analyzed and preprocessed to improve the quality of the data. Experiments and comparisons indicate that the proposed model depicts high performances of 91% accuracy levels. The overall sensitivity levels record 86% and specificity levels record 94%. These performances show that the proposed ensemble modeling technique is highly suitable for mortality prediction in hospitals.

Keywords: Ensemble modeling; Semi Supervised Learning; Mortality Prediction; Multilevel Modeling; Decision Tree

INTRODUCTION

ICUs have effectively increased life span of people to a large extent. Patient admitted in the ICU's are considered to be critical and their health status is continuously monitored. General monitoring methods include analysis of medical complications and the critical health status of the patient. Patients in ICU's generally require special care compared to other patients. They also require time sensitive medical responses, as their health status is very critical in nature.

Mortality levels of patients are mainly dependent on the quality of care provided to them in ICU [1]. Prognostic decision-making is one of the major qualities requirements in hospital administration, especially in ICUs. APACHE and SAPS are some of the mainly used case based reasoning methods in ICU's [2]. However, several issues were observed in these models. Some of them include, ambiguous interpretation of the results [3], poor generalization, and bias [4]. Increasing digitalization has resulted in electronic health record maintenance systems. These systems record every single process from admission to treatment details of the patient. This ensures that personalized and data driven predictions are made possible [5]. Availability of all these details has provided the advantage of using machine learning models for mortality prediction. Demand for hospital beds are increasing at enormous rates [6] due to the unhealthy lifestyle and food habits of people. The increase in demand mandates an equivalent increase in hospital facilities. However, beds, medical staff and medical equipment are still limited in nature [7]. Decisions made in critical times impact heavily on the health and survivability levels of patients, due to the limited available facilities [8]. Resource allocation is a huge issue faced by hospital management [9]. Correctly identifying surviving patients and non-surviving patients can aid in effective allocation of resources and equipment. This work proposes a multi-level based modeling technique that can be used for accurate mortality detection in ICU patients.

RELATED WORKS

Mortality prediction has become an essential requirement of a hospital management system. Effective health care can be provided by accurate prediction of mortality levels. This section discusses some of the existing mortality prediction models for health care system. An unstructured mortality prediction model was proposed by Hashir *et al* [10]. This model was developed by performing analysis based on textual clinical notes. A hierarchical architecture has been created composed of convolutional and recurrent layers. The two models concurrently provide predictions for an individual patient. The model uses unstructured data for the prediction process. Multiple machine learning model based mortality prediction technique was proposed by Chia *et al*. [11]. This model uses white box feature selection methods like logistic regression and decision tree, and also extreme gradient boosted trees for improved performance. An interpretable deep learning model for mortality prediction in ICU was proposed by Torres *et al*. [12]. A deep convolutional architecture proposed by this model. The concept of game theory was used to create visual explanations that makes this model highly interpretable. The interpretable nature of this model ensures better understanding by medical practitioners. A deep autoencoder model for clinical analysis it was proposed by Lasko *et al*. [13]. This is an unsupervised technique that uses measurements to analyse and provide the results. A feedforward deep learning model for mortality prediction was proposed by Che *et al*. [4]. The model uses sigmoid activations to predict the survivability levels. A stacked denoising auto encoding model for paediatric intensive care unit to detect mortality rates was proposed by Kale *et al*. [15]. A neural network based model that uses recurrent neural networks to provide an interpretable mortality risk prediction technique was proposed by Ho *et al*. [16]. This technique aims to improve the interpretability levels by using learned binary masks, and by applying KernelSHAP. Both the techniques are used to generate the predictions. The predictions are finally aggregated to identify the mortality levels. Other similar techniques that use deep learning models for interpretable predictions include works by Cerna *et al*. [17], Choi *et al*. [18], Zhang *et al*. [19], Sangdeh *et al*. [20] and Ding *et al*. [26]. A sampling in feature selection based model using neural networks for mortality prediction was proposed Steinmeyer *et al*. [21]. The model mainly concentrates on creating a generalizable architecture that is flexible and can utilize large volumes data. The model also uses an extensive preprocessing pipeline to ensure high quality data. Other feature selection based models you perform mortality prediction includes an automated technique by Celi *et al*. [22],and a free text based feature construction method by Ghassemi *et al*. [23] which performs in hospital, 30 day post discharge, and one year post discharge mortality. A mortality prediction model that uses relationships between the health care processes was proposed byMandalapu *et al*. [24]. The work uses for machine learning models, decision tree, gradient boosted tree, logistic regression and random forest. The significance factors were identified from these models and the mortality levels were predicted. An ensemble based model for predicting mortality levels was proposed by Guo *et al*. [25]. This is a dynamic ensemble based modelling technique, which selects one of the existing ensemble models for the prediction process. K-Means sampling and distance based dynamic ensemble technique are used for this process.

Semi Supervised Ensemble Integrated Model (SEIM)

Mortality prediction is one of the much required analysis that is to be performed for patients getting admitted in ICU. Effectively predicting mortality levels can aid in the process of determining the medicines and treatments to be provided for patients. This work presents a semi-supervised ensemble integrated model for mortality prediction. The proposed model is composed of two major sections; the patient grouping model and ensemble model for prediction.

Patient Detail Integration

The proposed model has been implemented based on the MIMIC III dataset. Data is divided into multiple files and stored in the mimic data set. The data files are created based on the departments from which the data has been recorded. Hence, the initial process is to identify the required data features that are to be used for modeling. This mandates the need for integrating multiple data files. The process of integration is based on patient ID, which is used as the unique identifier for each patient. The medical history of each of the patients can be determined using the patient ID. The length of stay of a patient in the ICU can be determined from the ICU details dataset. The current treatments administered to a patient can be obtained from the admission ID. Mortality levels is usually predicted with the current treatment, and the patient's disease history. Processes that are performed during the current treatment Are you stash are used as the major components in the current production mechanism. Expiry flag is the feature that contains value which determines the mortality state of a patient. The expiry flag is used as the class variable.

Data Cleaning and Preprocessing

The training data is determined by margin merging multiple files, as discussed in the previous section. Each file is composed of a different identifier. Some data files are based on patient ID, while others are based on admission ID. Personal details of a patient and the medical history pertaining to patients is determined using the patient ID. Current treatments performed on the patient and their stay details are determined using the admission ID. The details are accumulated unintegrated from several files. Hence, that is a huge possibility of occurrence of a large number of null values. Hence the first process performed in the preprocessing phase is to separate the numerical and the categorical attributes. The null values contained in numerical values are imputed using median based imputation techniques. Null values in categorical attributes are imputed using mode based imputation techniques. The next preprocessing step is to convert the categorical attributes to numerical features. Analysis of the data shows that the diagnosis feature contains large number of distinct values. Categorical encoding methods create a single feature for each existing unique value. Hence, it is required to reduce the number of distinct values in the diagnosis attribute. Value based counting shows that several unique treatments were provided for one or two patients only. Hence, treatments that were provided for less than 20 patients are grouped into a single value. This process was observed to effectively reduce the number of unique values. The attribute determining the treatment process is coded with ID numbers. These values are numerical, however, they are logically categorical entities. Hence the two features are converted to numerical values using one hot encoding technique.

Patient Grouping for Semi Supervised Learning

The next process is to group similar patients into single entities to ensure data similarity, which can in turn in better predictions. The expiry flag feature is removed from the data and is passed to the clustering algorithm. K means clustering is used as the grouping algorithm of choice. The number of clusters for the K means algorithm is set to two. In the initial iteration, two random points are selected from the data set and are set as the cluster centroids. For each point, its distance from the centroids is measured. The process of measuring the centroid distance is given by,

$$D = \sqrt{\sum_{x=1}^{n} (x_2 - x_1)^2}$$

Where $x_1$and x_2 are the values contained in the two compared points in the feature x, and n is the total number of features.

The points are grouped to the centroid that exhibits lowest distance levels. Two groups of data are found. Formed. Centroid for each group is again identified. The process of distance identification with the new centroids is performed. This is followed by distance based grouping and identification of new centroid. The process is repeated until the centroids do not change. The cluster labels for each of the data points is identified and is appended to the training data.

Bagging Based Second Level Analysis

Data updated with the cluster information is passed to the bagging model for second level prediction. Bagging is an ensemble based modeling technique. This technique creates multiple subsets of data for the training process. Each data subset is composed of 60% of the entire training data. Selection of data for creation of the data subsets is done in random. Decision tree model is used as the base learner for the bagging model. Decision tree is it three based modeling technique. Decision rules are modeled using entropy levels of the features. Decision rules are identified by traversing the tree, beginning at the root, and moving through the parts of the tree up to the leaves. The leaf nodes contain the final predictions. Multiple decision tree models are created for the ensemble learning process. Each decision tree model is trained with a different subset of the data. Hence, each model is composed of a different set of decision rules. The test data is passed to the clustering model to identify the cluster label. The identified cluster label is integrated with the data and the updated test data is passed to the bagging model for prediction. Every instance of the test data is predicted by by every model. Hence multiple predictions are obtained for each of the instances. Mean based prediction aggregation is performed to integrate the predictions, and the final prediction set is obtained.

RESULTS AND DISCUSSION

Mortality prediction performance of the proposed SEIM model is validated using the MIMIC III data set. Classification report depicting the performance of the SEIM model is shown in table one. The classification report shows precision, recall and F1-score of the model. Class based metric analysis is shown in the table. Class 0 represents negative mortality (patient was alive) and class 1 represents positive mortality (patient was not alive). It could be observed that the precision, recall and F1 score levels of both the classes shows high performance. Further, the accuracy level of the model was observed to be 0.91. This depicts that the proposed SEIM model exhibits effective detection rates. Roc curve representing the sensitivity and specificity levels is plotted on metrics obtained from SEIM and Ding *et al*. [26] (Figure 1). High sensitivity and specificity levels represent effective performances in the classification process. Highest point in the graph depicts the best performance. It could be observed that performance of the SEIM model occupies the highest point compared to the model by Ding *et al*. This shows is that SEIM model exhibits high sensitivity and high specificity levels indicating effective identification of mortality levels. Comparison of the aggregate metrics, accuracy, sensitivity and specificity as shown in figure 2. The comparison shows that SEIM model exhibits improved accuracy levels, and also improved sensitivity and specificity levels. Efficiency in accuracy indicates that the model exhibits overall good performance. High sensitivity and specificity indicates that the model exhibits high detection levels for both the classes. Comparison of the positive predictive value and the negative predictive value is shown in figure 3. Positive predictive value indicates efficiency in predicting patients who have high probability of mortality. Negative predictive value indicates efficiency in predicting patients you have low probability of mortality. Although the SEIM model indicates slightly reduced NPV levels, the PPV levels of SEIM shows that it exhibits very high performances of greater than 90%. This indicates that the model is highly suitable in predicting mortality in patients. Tabular view of the performance comparison is shown in table two. The best performances are highlighted in bold. It could be observed that the SEIM model exhibits high performance is in all the other metrics other than NPV levels. A slight reduction of 3% in NPV levels was observed, however, improvement levels of 24% in accuracy levels, 20% in sensitivity levels, 28% specificity levels, and 37% in PPV levels were observed. The highest level of improvement in performance levels indicates that the model is suitable for usage in predicting mortality levels among patients in real time.

CONCLUSION

Effectively identifying mortality levels is one of the major requirements of a hospital management system. Correct identification of mortality levels can aid in determining the correct treatment process. Hospitals can also perform efficient allocation of resources by accurate prediction of mortality levels. This work presents a two level model that can be used for effective mortality prediction. The architecture of the proposed model begins with identifying the correct features required for the training process. The proposed SEIM model is composed of two phases. The initial data grouping phase, groups similar patient data. The second level analysis is performed by the bagging based model that provides the final prediction. Experimental results and comparisons indicate high efficiency in identifying mortality levels at 90% accuracy. However, a slight reduction in NPV values shows that the model still exhibits scope for improvement.

ABSTRACT

In today's world Mental health care has seen a significant evolution in the use of technology. In recent times machine-based systems for diagnosis, treatment planning, and patient engagement have been more widely used.Yet, this shift in technology has occurred faster than its accompanying legal and ethical considerations, particularly in developing regions where mental health laws are still formative. This paper seeks to critically analyze the legal and ethical implications with respect to the employment of technology in mental health care. It attempts to fill the gap in the relevant legislative framework created by the Mental Healthcare Act 2017 and raises ethical questions concerning the use of automation for therapeutic interaction. The study utilizes qualitative, doctrinal research methods. It includes analysing legislation and published works on the intersection of mental health law and digital health technology.It also analyzes other jurisdictions to determine best and benchmark practices and standards. The issue of responsibility and accountability, harming a person, and use of closed algorithms, remain untouched in contemporary legal discourse and is sub neglectus. Affective and algorithmic biases due to lack of representative data along with diminishing human involvement in mental health care delivery increase ethical scrutiny. The absence of comprehensive data protection provides further and aggravates concerns over patient privacy and trust. To ensure the responsible integration of digital systems into mental health care, a comprehensive regulatory framework is indispensable. This framework should comprise modernized legal provisions, ethical surveillance, and data protection safeguards. Balancing accountability with innovation will be key to safeguarding the rights and welfare of people seeking mental health services.

Keywords: Healthcare, Diagnostic tools, Algorithmic transparency, Technology development, Algorithmic bias

INTRODUCTION

Good mental health is directly proportional to mental and psychological welfare. WHO's work to improve the mental health of individuals and society at large includes the promotion of mental well-being, the prevention of mental disorders, the protection of human rights and the care of people affected by mental disorders. Mental, neurological and substance use disorders make up 10% of the global burden of disease and 25.1% of non-fatal disease burden[1]. In India, the mental health workforce faces a significant shortage, with only 0.7 mental health professionals per 100,000 people, far below the recommended ratio of three per 100,000[2]. This shortage is expected to worsen, with projections indicating a growing gap in the availability of mental health professionals.[3] Regarding depression and anxiety, the rates have also seen a sharp increase. During the pandemic, the prevalence of depression and anxiety among Indian adults rose to 14%, compared to 5.3% before the pandemic. This highlights the urgent need for more mental health resources and support in the country[4]. The integration of artificial intelligence (AI) in mental health care is revolutionizing the field, offering innovative tools to enhance diagnosis, treatment, and accessibility. However, as these technologies become more prevalent, they raise critical legal and ethical concerns that must be addressed. AI has significantly transformed various aspects of human life. Its primary goal is to create intelligent systems capable of learning, understanding, and providing guidance to users. Machine learning (ML), a subset of AI, uses statistical models and algorithms to extract features and recognize patterns from extensive data sets. Artificial intelligence (AI) significantly impacts healthcare, especially through machine learning (ML). Three main types of ML are utilized: supervised learning, unsupervised learning, and deep learning. Supervised learning involves training models with labeled data for applications like disease diagnosis by identifying patterns in medical images and predictive analytics to forecast patient outcomes based on historical data. Unsupervised learning uses unlabeled data to discover hidden patterns, aiding in tasks such as grouping patients with similar traits for customized treatments and detecting anomalies in patient data that might indicate errors or rare conditions. Deep learning, a branch of ML, employs multi-layered neural networks for analyzing data, proving effective in tasks like detecting abnormalities in complex medical images, understanding clinical notes through Natural Language Processing (NLP) for informed clinical decisions, and accelerating drug development by predicting molecular behavior and drug interactions. These ML techniques are enhancing healthcare by improving diagnostic accuracy, personalizing treatments, and streamlining administrative processes, marking an exciting era for AI in the medical field. AI tools such as predictive analytics, chatbot-based therapies, and virtual mental health assistants have transformed how care is delivered. Despite these advancements, issues surrounding data privacy, algorithmic bias, and accountability highlight the urgent need for a robust legal and ethical framework. This paper examines the implications of AI in mental health, while proposing solutions to ensure that innovation aligns with legal and ethical principles.

AI in Modern Life

AI has become a significant part of our daily lives. The term "artificial intelligence" was coined by computer scientist John McCarthy, who described it as the science of creating intelligent machines. Another key figure, Alan Turing, discussed the criteria for machine intelligence in his 1950 paper "Computing Machinery and Intelligence." While intelligence is traditionally associated with humans, the term "artificial" highlights that this type of intelligence is computer-based. AI is now widespread in modern western society, assisting with information access, social media interactions, and security systems. Although AI is starting to be utilized in clinical settings, such as medical imaging and genetic testing, its routine use in healthcare is still limited due to the high stakes and potential risks compared to its application in everyday conveniences.

AI in Health-Care

AI has revolutionized healthcare by enhancing early disease detection, understanding disease progression, optimizing treatment dosages, and discovering new therapies through rapid analysis of large datasets. In fields like ophthalmology, cancer detection, and radiology, AI algorithms can identify patterns and subtleties undetectable by humans. Although AI won't completely replace human doctors, it supports clinical decision-making by synthesizing vast amounts of medical information quickly. Large datasets, such as Electronic Health Records (EHRs), enable AI to reveal trends and associations in human behaviors that are challenging for humans to extract, ultimately augmenting healthcare professionals' capabilities and enabling more precise, personalized medical care. Moreover, Virtual consultations allow patients to receive medical care remotely, which is particularly useful for those in remote locations or with mobility challenges. AI also plays a crucial role in medication management by analyzing prescription histories and vital signs, reducing the risk of adverse drug events and enhancing patient safety. Furthermore, AI fosters transparency by providing patients with detailed information about their health and treatments, empowering them to make informed decisions and fostering trust with healthcare providers. Three core principles for the successful integration of AI in healthcare are data security, analytics and insights, and collaborative expertise. Ensuring data security involves maintaining full transparency and trust in the training processes of AI systems, as well as in the data and knowledge utilized to train them. As humans and AI systems increasingly collaborate, it is crucial to have confidence in the outcomes produced by these systems[5]. AI algorithms can analyze data and generate predictions, uncovering insights that were previously out of reach. In the healthcare sector, AI-powered diagnostic tools have demonstrated high accuracy and efficiency in disease detection. By scrutinizing vast amounts of medical data, these technologies can identify patterns and make predictions with notable precision. For instance, AI algorithms can assess medical images, such as MRIs or X-rays, to detect abnormalities that human experts might miss. This technology improves early detection rates and has the potential to prevent numerous fatalities.

AI in Mental Health-Care

AI's development can be traced back to the mid-20th century when initial models and algorithms started to imitate human cognitive processes. The British Computer Scientist Alan Turing is considered a pioneer of artificial intelligence (AI) and the father of modern cognitive science. A key moment in this evolution was the development of the program named ELIZA (Electronic Linguistic Analyzer) by Joseph Weizenbaum in the 1966, who was highly influenced by the Turin's work of machine intelligence and whether machines can exhibit human like behaviour. ELIZA used a basic natural language processing (NLP) system designed to emulate conversation and make structured dialogue to mimic human interaction. ELIZA's response was based on program scripts and patterns rather than true comprehension of the conversation. During the 1980s and 1990s, expert systems were introduced to assist with mental health diagnosis and treatment planning, aiming to mirror human decision-making. However, these early AI applications faced limitations, including insufficient computational power, limited data, and the underdevelopment of machine learning techniques[6]. More than 150 Million people in 2021 in the WHO European Region were suffering from serious mental health condition, which got aggravated by the covid scenario. Loss of employment, professional and academic stress, lacking access to health services turned the mental health condition of the people vulnerable. As AI has revolutionized health care facility where it helps to identify and monitor health problems [7]. In the 21st century, AI's role in mental health saw a major shift, driven by advancements in machine learning, NLP, and the rise of digital health data. AI systems evolved from rigid, rule-based models to ones that could learn from data, enabling them to make predictions and derive insights. This period saw the development of AI applications for mental health assessment, diagnosis, and even initial clinical interventions, forming the basis for contemporary AI use in the field of mental health. As a branch of artificial intelligence, machine learning (ML) entails developing algorithms that let systems learn from data and gradually get better at what they do without explicit programming. It encompasses methods like deep learning, reinforcement learning, supervised learning, and unsupervised learning. Mental health issues including schizophrenia, anxiety, and depression can be diagnosed with the aid of machine learning algorithms using patient data, including behavioral patterns and electronic medical records[8]. Another branch of artificial intelligence that enables machines to analyze, understand, interpret, and generate human language is called natural language processing, or NLP. Researchers enhance and use these

methods in practical applications, like creating speech-to-speech translation engines and spoken dialogue systems, searching social media for financial or health information, and identifying sentiment and emotion toward goods and services[9]. Clinicians can keep an eye on their patients' mental health through text, chat, or speech by using natural language processing (NLP) to evaluate written or spoken language and identify emotional states and changes. Additionally, this potential is increased by using AI-powered chatbots, which engage users in text-based conversations and provide real-time assistance, coping mechanisms, and even recommendations for mental health specialists to consult. In India the Ministry of Electronics and Information Technology launched Tele MANAS (Tele Mental Health Assistance and Networking Across States) under The National Tele Mental Health Programme (NTMHP) on 10th October 2022. Its aim was to provide 24/7 affordable and quality free mental health care assistance to every citizens of India specially to vulnerable groups and in remote areas. The service includes phone based consultation and counseling. It served over 14.7 lakh calls till today[10].

Legal Challenges of AI in Metal Health-Care

Mental health and issues related to it have been considered to be a taboo in Indian society for a long time. It includes a vibrant stigma attached to those who suffer from it. This stigma has led to mistreatment, abuse, and isolation of individuals with mental health related issues, mostly in backward sections of the country where they are sometimes labelled as "lunatics." India's legal administration for AI is still in its nascent stages. As exploration of AI in different fields is very new, Its administration is mostly based on existing regulations that are not adapted to the specific issues which comes along AI systems. Data is the foundation of this technology, so effective data handling, including privacy and security, is critical. Challenges include data collection without consent. The quality of data used to train AI models if inaccurate then it can lead to critical problem in real world application. AI systems often rely on large amounts of data, which many times include sensitive personal information, the breach of which may lead to serious problems. AI algorithms can provide biased output if the input data they are trained on is also biased. This can lead to discriminatory outcomes. AI systems can occasionally become targets for hackers seeking illegitimate access to personal information. Highest critical component of AI regulation is protection of personal data. The Digital Personal Data Protection Act, 2023 mandates that the gathering and subsequent utilization of personal data need to be lawful, fair, and transparent. It emphasizes the need for data minimization and the prevention of discriminatory outcomes. It promotes transparency by requiring data fiduciaries to provide individuals with clear information about how their data is being used, indirectly addressing algorithmic bias concerns. It establishes a framework for the protection of personal data, emphasizing consent, data minimization, and accountability but does not provide a dedicated AI regulation. But it acts as a foundational framework for responsible AI development and use in India by focusing on the ethical and lawful handling of personal data. The Information Technology Act, 2000 in India was enacted before the extensive adoption of AI. As a result, it faces several challenges in effectively regulating AI-related issues in today's world. Though the IT Act provides a framework for data protection, addresses cybersecurity concerns, provides a legal framework for e-commerce transactions.

But it lacks specific provisions explicitly addressing AI-related issues. The rapid evolution of AI technologies presents a significant challenge for the IT Act, which may not keep pace with the latest advancements in the fast changing world. Moreover, the IT Act does not directly address the issue of algorithmic bias, which can lead to discriminatory outcomes in areas. Thus the Act does not specifically address AI centric problems with respect to applications of AI, leaving gaps for a more comprehensive legal framework to address the unique challenges evolved with AI technologies. This may require amendments to the IT Act or the enactment of new legislation specifically AI centric. The core legislation that deals with mental health in India in Mental Healthcare Act, 2017. This Act replaced the Mental Health Act 1987 The previous Mental Health Act of 1987 was outdated and did not provide for adequate protection or curative treatment to the individuals suffering from mental illness. The Act primarily focused on institutional care of the patients in psychiatric hospitals, neglecting community-based treatment. This prevented these people with mental illness to live independently and intricately participate in society. The concept of confinement, including the use of chains and other extreme measures, were seen as a way to protect society from persons with mental illness rather than providing them with proper care and provide a reformative treatment. With the aim to align the mental healthcare domain with United Nations Convention on the Rights of Persons with

Disabilities (UNCRPD) in 2007, the previous Act of 1987 got repealed, leading to the introduction of the new Act. The Act does not have any explicit provision relating to protection of patient's data used by AI system which can lead to breach of confidentiality. The Act does not addresses any concern regarding development and use of AI technique in mental healthcare. The Act also does not provide for any provision which ensures AI technological access to remote areas. India's legal landscape for AI is still in its beginning stages, with fragmented legislation and a lack of a specific AI regulatory framework. While AI has been recognized as a transformational technology, its administration is mostly based on existing regulations that are not adapted to the specific issues brought by AI systems. The National Institution for Transforming India (NITI Aayog) issued the "National Strategy on Artificial Intelligence" in 2018. Though technology has the transformative capability yet it is in its initial stage, so it provides India to define its own area in AI leadership. This document recognizes artificial intelligence as a crucial path maker of India's progress and focuses on five sectors that are considered to benefit the most through the use of AI in solving societal problems. These five sectors are healthcare, agriculture, education, smart cities and infrastructure, and smart mobility and transportation. It covers issues like data privacy, security, and ethics and underlines the significance of ethical AI usage, governance, and responsible AI deployment. However, the approach is largely concerned with boosting AI adoption and does not include extensive regulatory systems to handle ethical, legal, and social issues[11]. The foremost legal challenges in integrating AI into mental health care is data privacy. Mental health data is highly sensitive, and its misuse can have profound consequences for individuals. Current Indian laws, including the Information Technology Act, 2000, and the Mental Healthcare Act, 2017, offer limited guidance on regulating AI applications and ensuring data protection. Additionally, issues of liability remain unresolved. For instance, determining accountability in cases where an AI system provides inaccurate diagnoses or advice is a complex legal question. Another key difficulty is the absence of transparency in algorithms used by AI, which makes it impossible to determine how judgments are reached and whether they are bias-free.

Ethical Implication of AI in Mental Health-Care

One of the foremost ethical challenges of use of AI in Mental Healthcare is application of Black Box AI in mental Healthcare. This technology is used for many purposes like Chatbots and Virtual Assistant in places where Mental Health Professionals are scarcely accessible or accessibility is limited. It is used in the field of Research and Drug Development and Discovery, firstly to analyze any type of biological data like blood test or physiological responses and also to analyze psychological data like questionnaires responses, therapy session outcomes, facial expression etc. It is used in identifying the biomarkers related to mental health conditions by scrutinizing the data. After analyzing the data and identifying the biomarker for a particular patient it can specific treatment that will allow the patient to respond quickly. The AI can also analyze the plethora of chemical compounds which can be used to cure the mental problem of that patient and also the possible side effects. Now this Black Box Ai uses a complex algorithm and calculation to calculate and analyze the large amount of data and to provide unique solutions to the problems which are generally not easily solvable by human intelligence. The logic and data used to reach the output by this Black Box AI are not accessible, making how they operate becomes unclear. The other ethical challenge includes privacy and confidentiality of large amount of sensitive data of public. For instance the Unique Health Identification (UHID) system initiated by All India Institute of Medical Sciences (AIIMS) to provide randomly generated 14 digit number under the Ayushman Bharat Digital Mission regardless of whether they have visited AIIMS or any other specific hospital. Now after 2016 AIIMS asked the Gov. to link the same number with Aadhar for centralized storage of patient's health record.

Though it is still not mandatory and is under consideration but implementing it will primarily attack the confidentiality of patient's data and moreover private hospitals may be reluctant to share their patient's data. Apart from these diagnosis by machines having artificial intelligence instead of humans with their human intelligence makes the process very mechanical and not empathetic. The human-machine interaction will be looked down in place of long practice of human-human interaction. Though the AI can be super accurate and efficient in diagnosis and detecting ailments but it lacks the compassionate and empathetic nature which can never be achieved by robotic doctors. So the inclusion of AI can cause disturbance the therapeutic relationship, which is crucial for effective mental health care. The automated care delivery raises questions about the erosion of the human connection, which is central

to mental health treatment. It also must be taken into consideration that while training the the AI models the data they are fed on for a particular work may sometimes not sufficient to represent the total diverse society. It sometimes lead to incorrect diagnosis and treatment. On a serious note humans do express their emotions and wellbeing through their way to speaking. For instance patients suffering from depression is more monotonous and express them slowly. While a person with anxiety disorder may have higher pitch and talks nervously. These humanistic behavior may sometimes be overlooked by automated machine centric systems which understand and take the input problem based upon a particular training. which many times lacks the intelligence and compassion to understand human moods[12].

RECOMMENDATIONS

Chatbots in mental healthcare provide immediate support and assistance any time anywhere especially to those who are reluctant to get traditional mental healthcare. However, incorporating chatbots in mental healthcare must be combined with strong ethical criteria to assure the usefulness and safety of these digital solutions[13]. It is vital to safeguard the user's privacy, anonymity, and data security. Furthermore, it is crucial that the system used to handle this data maintains transparency regarding their collection, storage, and utilization. This transparency builds trust between users and chatbots. There must be a Global Standard about privacy and confidentiality of what information are stored in the AI generated machines after the diagnosis and treatment of a particular patient. Moreover how such information are being communicated to the patient as compared to the communication by a doctor to his/her patient needs to be taken care. The Oviedo Convention, known as the Convention for the Protection of Human Rights and Dignity of the Human Being with respect to the Application of Biology and Medicine, is an international legally binding instrument which talks about the protection of human rights in biomedical fields. Though this convention is a legally binding instrument for Council of Europe and India is not a part of it and though it does not expressly talks about Artificial Intelligence related issues and its administration but it provides a framework for protection of human rights that can be applied with respect to Artificial Intelligence. In order to tackle the AI Algorithm bias the data which is fed on while training the AI generated machines must be representative of a range of demographic groups, economic strata, language, socioeconomic conditions. Such data must be balanced and cover the underrepresented population. The AI centric diagnostic machines must be programmed to understand diverse languages and dialects. Data labeling must take into account several views and cultural conventions.

It must be ensured that the AI algorithm can identify potential disparities across different demographic groups separately. Developers must evaluate AI models on a regular basis to update them when new data becomes available. The AI machines must also be programmed to understand human emotions to get accurate diagnosis and treatment, as the tone of a patient talks plethora about his current condition[14]. When AI makes any decision regarding the mental health of a patient, it uses the data that was previously programmed and fed in to analyze and make proper observation to give adequate treatment. But due to the use of black-box AI the factors upon which the diagnosis and treatment is made remains under suspicion and not intelligible. Thus in such cases use of Explainable AI (XAI) can reveal the factors and the reason behind the decision. It can also provide insights about the decision making process which will help the developers to make necessary improvements in the system. By understanding the rationale behind AI predictions, healthcare providers can provide effective treatment plans to individual patients. XAI is used in various systems that monitor an individual's behavior and well-being through data collected from wearable devices, apps, or other digital tools like smartwatches. It helps to explain the significance of monitored data and its consequences on that individual’s health. The use of XAI in mental healthcare is still in nascent stage in India but there are some applications of it in mental healthcare. Different AI powered mental healthcare apps like Wysa, Woebot, Joyable, and Talkspace are gaining popularity.

They provide round the clock support and makes mental healthcare easily accessible specially in remote areas[15]. As AI relies on a tremendous amount of personal data about an individual, protecting the privacy and confidentiality of those data is crucial. As data related to mental health of a person is highly sensitive data, so its protection is not only

a legal obligation but also an ethical concern. The Digital Personal Data Protection Act, 2023 and Mental Healthcare Act, 2017 both needs more refinement regarding accountability of AI centric decision, algorithm transparency. Though The Digital Personal Data Protection Act, 2023 talks about Data Minimization, it may provide explicit provisions regarding collection and storage of data with respect to mental health. The Act can provide provisions for informed consent i.e how the data collected by AI will be used. The Act can make strict provisions regarding auditing and monitoring of AI driven systems to ensure its compliance with data protection and ethical standards. Apart from such amendments, Data Encryption should be made mandatory to protect the personal data from unauthorized usage. The encryption will ensure that even if the data is accessed unauthorizedly, it will still remain unreadable. The access to such data must be protected with a multi-layered verification system. There must be strict provisions regarding limited and optimum data to be used and stored by the AI centered machines with respect to mental healthcare which will be needed for diagnosis and treatment. If treatment of a patient gets complete and the patient gets cured then there must be an integrated system of auto-deletion of the personal data related to that person.

The Mental Healthcare Act 2017 on the same note primarily focuses on the personal rights with mental illness, access to mental healthcare, provides a comprehensive framework for mental healthcare but does not provide any provision relating to AI or digital technologies directly. Thus provisions are required regarding bias mitigation, data minimization and informed consent. Transparency in AI systems is essential with respect to the outcomes is essential to allow both patient and authorities to understand the decision making process. For effective integration and application of AI in mental healthcare, a skilled workforce and Research and Development wing is necessary. Thus funding for AI education and training is essential for developing and deploying AI powered mental health tools. The AI developers must be trained to adhere to the ethical consideration of mental healthcare related matter and the health professionals must be trained to effectively use AI generated system. Providing scope for interdisciplinary research among AI experts, Legal professionals and mental health professionals is essential to ensure development and integration of artificial intelligence must at par with ethical, legal and social dimension of mental healthcare.

CONCLUSION

The integration of AI powered tools and systems into mental health care has revolutionized the accessibility, diagnosis mechanism and treatment recommendation in a country like India where there is an acute shortage of mental healthcare facilities. India is also a country where mental health related problems are looked down upon and also stigmatized. Thus inclusion of AI powered tools can facilitate individuals to make primary self diagnosis. But some areas must be addressed proactively while developing these technologies and these are data privacy, transparency and algorithm bias. It must be kept in mind that Virtual therapists rely on the data r=they are fed on by a human intelligence. Thus it can only go up to a certain point which its program supports and not beyond that. Though the integration of Ai in mental healthcare provides easy access to users to share and get personalized opinions regarding their mental health related problems without disclosing it to the family members and protecting anonymity but ironically this technology is also encouraging them to segregate themselves socially. As positive social interaction is one of the primary weapons to improve psychological well being. India's current legal framework is not sufficient to cope up with the emerging legal and ethical challenges that pop up with these new technologies. Digital Personal Data Protection Act, 2023 and the Mental Healthcare Act, 2017 though gives primary foundation but they require further refinement and amendments to specifically address AI related issues. Even if AI offers quick analysis and efficient solutions to the mental health related problems but it must be kept in mind that human empathy, compassion and therapeutic relation between doctors and patients are mostly preferred in any type of treatment from time immemorial. The former must not overshadow the latter. India must include mental health under health laws and provide a regulative privacy protection framework which also needs to be updated on a regular basis. Lastly on one hand the stigmatization of mental health related problems must be erased from the mind of the general public through several campaigns., and on the other hand faith must be generated in their mind with respect to the use of AI in mental healthcare emphasizing improved outcomes and increased access for remote

population. The population must endeavored trust in the system concerning the privacy and confidentiality of their personal data. The AI and the machines must be an aid to human intelligence but not a master of it.

ABSTRACT

Surface engineering plays a very important role in improving the wear resistance, hardness, and performance of engineering components. Amongst various surface modification techniques, hardfacing has emerged as an efficient technique for extending component life by deposition of hard, wear-resistant materials onto softer substrates. This work deals with the surface hardening of Al using SiC as the reinforcing material via the friction surfacing technique. Al was selected owing to its excellent mechanical and thermal properties with limited tribological performance. SiC powder was preplaced on the Al substrate and friction surfaced using a die steel tool on a universal milling machine. The mechanical characterization was performed by Vickers microhardness testing. Experimental results indicated a substantial improvement in hardness: the hardfaced Al surface exhibited a Vickers microhardness of around 345 HV, approximately eight times that of untreated Al substrate (40 HV). The present study reveals that friction surfacing with SiC reinforcement enhances the surface properties of Al effectively, thus making it suitable for industrially demanding applications in the automotive, aerospace, and energy systems. Process parameter optimization and studies on coating microstructural evolution can be subjects of future investigations for further coating performance improvements.

INTRODUCTION

Surface degradation in the form of wear, corrosion, and fatigue is a critical challenge that limits the service life and efficiency of engineering components. In most cases, failure of machine parts occurs not due to bulk fracture but because of surface deterioration caused by frictional wear or chemical attack. Therefore, improving surface performance without altering the bulk material properties has become a vital engineering necessity. This has led to the evolution of surface engineering, a multidisciplinary field that focuses on modifying or enhancing the surface characteristics of materials to achieve superior mechanical, tribological, and chemical performance. The techniques used in surface engineering can significantly enhance component durability, reduce maintenance costs, and improve overall system efficiency. One of the most prominent surface modification methods is hardfacing, which involves depositing a layer of hard, wear-resistant material over a relatively softer substrate to improve its surface properties. Hardfacing is commonly applied using processes such as arc welding, plasma transferred arc (PTA), laser cladding, and thermal spraying. The resulting coatings improve resistance to wear, corrosion, and fatigue while extending component life in demanding environments such as mining, power generation, cement, and automotive industries. However, these conventional techniques typically involve melting and solidification of materials, which may cause undesirable effects such as dilution, residual stresses, microcracking, and thermal distortion. These challenges have encouraged the development of solid-state surface modification techniques, which operate below the melting point of the substrate, thereby minimizing such defects. Among solid-state processes, friction surfacing has emerged as a promising and environmentally friendly surface modification technique. Derived from the principles of friction welding, this process employs a rotating consumable rod, termed a "mechtrode," that is pressed against a stationary substrate. The frictional heat generated at the interface softens the mechtrode material, enabling it to plastically deform and deposit onto the substrate surface. The resulting coating forms through solid-state bonding, characterized by a fine-grained microstructure, strong adhesion, and minimal dilution.

The process offers several advantages, including high deposition efficiency, low distortion, and the ability to produce dense, defect-free coatings without the use of filler metals or shielding gases. Furthermore, friction surfacing is a green and sustainable technology due to its low energy consumption and absence of harmful emissions. Aluminium and its alloys are widely used in industries such as aerospace, automotive, and marine due to their low density, high strength-to-weight ratio, and excellent corrosion resistance. Despite these advantages, their low surface hardness, poor wear resistance, and high coefficient of friction restrict their application in high-wear environments. Enhancing the surface properties of aluminium through appropriate surface modification techniques can therefore expand its usability in critical engineering applications. Conventional approaches such as anodizing, thermal spraying, and laser cladding have been used for this purpose, but these methods often suffer from limitations like weak adhesion, surface cracking, and high processing costs. In this context, friction surfacing offers a potential solution for surface hardening of aluminium without melting or thermally damaging the substrate. To further enhance the wear and hardness characteristics, reinforcement with hard ceramic particles, such as silicon carbide (SiC), is an effective strategy. SiC possesses high hardness, excellent thermal stability, low density, and strong chemical inertness, making it an ideal reinforcement material for aluminium-based surface composites. Incorporating SiC particles into aluminium through friction surfacing can produce a composite surface layer exhibiting superior hardness and wear resistance suitable for severe operating conditions. Although numerous studies have investigated friction surfacing on ferrous substrates, research on friction surfacing of aluminium using SiC reinforcement remains relatively limited. The development of a SiC-reinforced surface layer on aluminium via friction surfacing could therefore open new avenues for lightweight, wear-resistant material systems, particularly for automotive, aerospace, and structural applications where both high strength and low weight are desired.

Earlier Works

Wear is one of the most common factors affecting the service life of machinery parts. It is usually wear, rather than fracture, which causes the dimensional inaccuracy and eventual loss of a metal part. There are several types of wear: abrasive, impact, adhesive-metal-to-metal, thermal, and corrosive. In many applications, the actual operating

conditions involve several of these modes. The development of methods and materials to combat wear has hence been an important field in materials engineering. Hardfacing is a surface modification technique that has gained widespread attention within recent decades toward achieving wear performance and thereby increasing component life. Indeed, several materials and processes have been tested to develop appropriate hardfacing alloys, coating composition, and deposition techniques for optimum wear behavior. As specified by Berns *et al*. (1997), hardfacing alloys can be grouped into four major categories based on their composition: Low-alloy iron-base alloys contain alloying elements like chromium, molybdenum, and manganese up to a total of about 12% and are used for increased wear and corrosion resistance. High-alloyed iron-based alloys have alloy content in the range of 12-50%; the addition of chromium, nickel, and cobalt are common. These materials have enhanced hardness and exhibit resistance to oxidation (EL Mansori *et al*., 2007; Fouilland *et al*., 2009).There are several base-cobalt alloys, such as Stellite, which enjoy excellent resistance to wear and corrosion at high temperatures. They retain high hardness up to 800°C (Riddihough, 1970; Fouilland *et al*., 2009).Nickel-based alloys, such as Ni–Cr–B–Si systems, demonstrate low friction and excellent oxidation resistance at high temperatures (EL Mansori *et al*., 2007).According to Blombery and Perrott (1974), tungsten carbide (WC) is one of the hardest industrial materials used for hardfacing applications. Generally, it is embedded in a metallic matrix as cermets for enhanced wear resistance. More recently, tube rods filled with tungsten and vanadium carbides have been developed to ensure more uniform surface coverage and improved performance. Presently, steel remains the most used base material for hardfacing applications, constituting around 85% of the total industrial consumption. The suitability of a steel substrate for hardfacing depends on its carbon and alloy content. Low-carbon and low-alloy steels (AISI C-1008 to C-1020) are generally used because of their excellent weldability.

According to Wang *et al*. (2008), medium-carbon steels (AISI C-1025 to C-1050) offer better hardness and strength. However, their welding operations require greater care in controlling the respective parameters. High-carbon steels (AISI C-1050 to C-1095) require special precautions during welding due to their brittle nature, which might result in their cracking (Kwok *et al*., 2001).Other categories of steel used in hardfacing include low-nickel chrome steels, low-manganese steels, and low-alloy chromium steels such as AISI 5015–5160, among others. Material selection is based on the combination of weldability and wear resistance. Therefore, current research has shifted concentration to microstructural optimization in pursuit of better mechanical and wear properties of hardfacing coatings. Buchely *et al*. (2005) stated that the abrasive wear resistance is directly influenced by its microstructure. Chang *et al*. (2003) showed that with an increase in the fraction of complex carbides, high-temperature wear performance increases. Chieh Fan *et al*. (2006) and Chia-Ming Chang *et al*. (2010) also concluded that morphology and distribution of carbides like $(Cr,Fe)_3C_2$ and $(Cr,Fe)_{23}C_6$ are of paramount importance for achieving superior hardness and wear properties. Comparative studies by John Coronado *et al*. (2009) and Vernon Buchanan (2009) evaluated different deposition techniques, such as Shielded Metal Arc Welding (SMAW), Gas Tungsten Arc Welding (GTAW), and electric arc spraying, concluding that microstructural refinement and lower dilution significantly improve wear resistance. Navas *et al*. (2006) and D'Oliveira *et al*. (2002) highlighted that laser and plasma transferred arc coatings offer improved metallurgical bonding and high-temperature stability compared to conventional methods. Hardfacing of Aluminum Whereas a large amount of work has been done on steels, the studies related to aluminum and its alloys are rather recent. Aluminum is a material of choice due to its favorable properties such as low density, high thermal conductivity, and good corrosion resistance. However, the poor tribological properties of aluminum restrict its usage in wear-related applications. In this context, friction surfacing has emerged as one of the most promising solid-state, cost-effective, and eco-friendly techniques for surface hardening of aluminum substrates. Reinforcement by ceramic particles, especially SiC, can enhance the hardness and wear resistance remarkably.

MATERIALS AND METHODOLOGY

Material

Commercially pure aluminium (Al) was selected as the substrate material due to its widespread industrial use, lightweight nature, and excellent corrosion resistance. However, its low surface hardness and wear resistance

necessitate surface modification. The aluminium plates used in this study had dimensions of 140 mm × 100 mm × 10 mm. Prior to processing, the substrates were cleaned thoroughly using acetone to remove any surface impurities such as oil, dust, or oxide layers that could affect bonding quality. Silicon carbide (SiC) powder of 320 mesh size was chosen as the reinforcing material for hardfacing because of its high hardness, chemical inertness, and excellent thermal stability. The fine SiC particles were preplaced on the aluminium substrate surface before friction surfacing to facilitate uniform distribution within the surface layer during deposition. The friction tool was fabricated from die steel of 20 mm diameter, machined to the desired dimensions on an HMT NH22 lathe using tungsten carbide (WC–Co) inserts. The tool was designed to sustain the high frictional heat and pressure generated during surfacing without deformation or loss of strength. The friction tool was mounted on the vertical spindle of auniversal milling machine.

Equipment Setup

A 4 kW Universal Milling Machine (Model HPS 6336) was used to perform the friction surfacing operation. The setup allowed vertical rotation of the friction tool and controlled linear motion of the worktable to maintain a uniform traverse speed during the surfacing process. Before surfacing, slots of about 2 mm depth and 3 mm width were made on the aluminium substrate surface using the milling machine. These slots served as reservoirs to hold the SiC powder in place during the friction surfacing process. The SiC powder was gently packed into the slots to ensure uniform filling and even distribution. Fig. 1 shows the experimental setup.

Friction Surfacing Procedure

The friction surfacing process was performed by rotating the die steel tool at a specified speed while maintaining a constant downward axial force on the aluminium substrate. The friction between the rotating tool and the SiC-preplaced substrate generated sufficient heat to plasticize the surface layer of the aluminium without melting it. The softened aluminium, along with SiC particles, was then deposited and consolidated, forming a dense, metallurgically bonded surface layer.Schematic diagram of SiC placed in the slots of Alsubstrate shown in Fig. 2.

Sample Preparation and Characterization

After the friction surfacing process, the surface-hardened samples were sectioned, ground, and polished for characterization. The surface and cross-sectional morphology were examined visually to ensure the uniformity of the coating. The microhardness of the friction-surfaced zone was measured using a Vickers Microhardness Tester (Wolpert-Wilson, Germany). The test was conducted with a load of 50 g and a dwell time of 10 seconds. Measurements were taken at multiple points across the hardfaced surface and at different depths below the surface to determine hardness distribution. The average value was reported to minimize random variation. The Vickers hardness number (HV) was calculated using the standard relation:$HV = 1.854 \times (P / D^2)$where P is the applied load in kilograms-force (kgf) and D is the mean diagonal length of the indentation in millimeters (mm).The microhardness results of the friction-surfaced aluminium were compared with those of the as-received aluminium substrate to evaluate the effectiveness of the surface hardening process.

RESULTS AND DISCUSSION

The friction surfacing process was used in this experimental study to enhance the surface properties of commercially pure aluminum with the hardfacing agent SiC. The major emphasis was given to studying the improvement in the surface hardness and quality after deposition. Friction surfacing was performed using a die steel tool on a 4 kW universal milling machine, with SiC powder strategically placed in grooves on the aluminum substrate. Four distinct process parameter combinations were examined, altering the table feed rate (30 mm/min and 55 mm/min) and tool rotational speed (2000 rpm and 3220 rpm). The surface impressions obtained post-surfacing displayed a continuous and uniform layer with few visible defects, signifying effective adhesion and bonding between the coating and substrate. Surface hardness was measured by a Vickers microhardness tester (Wolpert-Wilson, Germany). The raw aluminum substrate exhibited an average hardness of about 40 HV, consistent with its naturally soft and ductile

nature. In contrast, the SiC-reinforced hardfaced aluminum surface exhibited a significant rise in hardness, reaching up to an average of 345 HV, reflecting an eightfold increase over the base material without treatment. Such significant enhancement could be related to the strong metallurgical bonding developed within the friction surfacing process and to the distribution of hard SiC particles that are well dispersed over the surface area. This improved hardness is essentially due to work hardening, a refined microstructure, and dispersion strengthening provided by the SiC particles embedded in the surface. The large rotational speed and frictional heat generated during surfacing resulted in localized plastic deformation associated with grain refinement and dislocation density increase in the aluminum matrix. In addition, the hard reinforcement of SiC acted as a barrier to plastic flow, thus providing increased resistance against indentation and wear. Surface morphology showed very limited porosity and a strong metallurgical bond, confirming the solid-state characteristic of friction surfacing that minimizes dilution and thermal distortion compared to fusion-based hardfacing methods. Results confirm that friction surfacing is a viable process for depositing hard, wear-resistant coatings onto lightweight metals such as aluminum without compromising structural integrity. In short, the friction-surfaced aluminum had superior mechanical properties for high-performance applications. The results reveal that friction surfacing with SiC hardfacing greatly improved the surface hardness, wear resistance, and service life of the aluminum parts. This process offers an economical and eco-friendly route compared to the conventionally used coating and welding techniques for several end-use industries such as aerospace, automotive, and power plants.

CONCLUSION

The present study successfully demonstrated the feasibility of surface hardening of aluminium using the friction surfacing process with silicon carbide (SiC) as reinforcement. The solid-state nature of the process enabled metallurgical bonding between the aluminium substrate and the deposited surface layer without melting or introducing thermal defects. The incorporation of SiC particles resulted in a composite surface with significantly improved mechanical performance.

The major findings of the work can be summarized as follows

- Friction surfacing provided a dense, uniform, and metallurgically bonded coating on the aluminium substrate using pre-placed SiC powder as reinforcement.
- The process parameters such as tool rotational speed and table traverse speed had a noticeable influence on the quality and surface finish of the hardfaced layer.
- The Vickers microhardness of the friction-surfaced aluminium reached approximately 345 HV, which is nearly eight times higher than that of the as-received aluminium substrate (~40 HV). This remarkable improvement is attributed to the presence of hard SiC particles and the fine-grained structure produced by the solid-state process.
- The use of friction surfacing, being a low-energy and eco-friendly process, minimizes material wastage and emissions, aligning well with the principles of sustainable manufacturing.

Overall, the study confirms that friction surfacing using SiC reinforcement is an effective and sustainable technique for enhancing the surface properties of aluminium. The developed surface layer exhibits superior hardness and potential wear resistance, making it suitable for applications in automotive, aerospace, and structural components where lightweight materials with high surface durability are required.

ACKNOWLEDGEMENTS

We want to express our sincere gratitude to each and every author for their significant contributions to this work.

ABSTRACT

In this paper, we introduce the concept of Possibility Plithogenic Hesitant Fuzzy Soft Sets (PP-HFSS),a hybrid model that combines hesitant fuzzy sets, soft sets, plithogenic theory and possibility measures along with some of their properties.Also, a decision making approach is developed with this framework to effectively handle uncertainty,hesitation and contradiction in complex environments.

Keywords: Hesitant Fuzzy Soft Set,Plithogenic soft set, Plithogenic Hesitant Fuzzy Soft Set, Possibility Plithogenic soft set,Possibility Plithogenic Hesitant Fuzzy Soft Set.

INTRODUCTION

In 1965, Zadeh [1] proposed the notion of fuzzy sets, which deals with probabilistic uncertainty and has been used in decision-making. Molodtsov presented soft set theory [4] in 1999 as a generic mathematical tool for dealing with uncertainties that standard mathematical approaches are unable to handle.Molodtsov has demonstrated several uses of this theory to address numerous real-world challenges in the fields of engineering, economics, social science, medicine, and more.Later on, Maji *et al*. [5] introduced fuzzy soft sets and developed various operations on soft sets and investigated their theoretical properties in [6]. Aktas and Cagman [8], Roy and Maji [9], Yang *et al*. [10], Majumdar and Samanta [11], Xiao *et al*. [12], and many more researchers have worked on this soft set theory concept, with a range of beneficial outcomes.In various real-world scenarios involving expert systems, belief systems,

information fusion, and other domains, it is necessary to consider both truth-membership and falsity-membership in order to represent an item in an unclear, ambiguous context. In this case, neither interval-valued fuzzy sets [2] nor fuzzy sets are appropriate. In such cases, Atanassov's intuitionistic fuzzy sets [3] are appropriate.Intuitionistic fuzzy sets can only handle incomplete data that includes both truth-membership (and simply membership) and falsity-membership (or non-membership) values. It does not address the ambiguous and conflicting information that exists in belief systems. Smarandache [7] developed the neutrosophic set, a mathematical technique for dealing with inconsistent, imprecise, and ambiguous data. Neutrosopic sets deal with three components such as membership, indeterminacy and non-membership. Torra and Narukawa [13] and Torra [14] proposed the concept of a hesitant fuzzy set to address the problem of defining the degree of membership of an element in a set.This new hesitant fuzzy set can handle situations where our hesitation among a few different values causes the difficulty in determining the membership degree.Thus, in contrast to the fuzzy set and its several classical extensions, the hesitant fuzzy set is better able to capture people's hesitancy when expressing their object preferences. The hesitant fuzzy element (HFE), first proposed by Xu and Xia [15] in 2011, is a simple and practical method for conveying the hesitating preferences of decision makers during the decision-making process. Several researchershave carried out a number of studies on decision-making with uncertain fuzzy data, clustering analysis, aggregation, distance, similarity and correlation metrics, and more.

Accuracy is one of the most crucial aspects of everyday decision-making. In order to improve accuracy, Smarandache's plithogenic [17] theory is characterized as a broader approach when compared to the existing theory which include intuitionistic, fuzzy, crisp, and neutrosophic sets. Plithogenic sets include degrees of appurtenance and contradiction with respect only to the dominant attribute. In 2017, Smarandache described a plithogenic set P as a set with elements specified by one or more attributes, each of which can have multiple values. A plithogenic set serves as the foundation for all plithogenic functions (plithogenic set, plithogenic probability, plithogenic statistics, and plithogenic logic), each of which is specified by a single plithogenic set appurtenance. Crisp sets have only one value (membership), fuzzy sets have two characteristics (membership and non-membership), intuitionistic sets have three characteristics (membership, indeterminacy, and non-membership), and plithogenic sets have four or more.Also, Alkhazaleh [18] made significant contributions to the theoretical development of Plithogenic soft sets, operations, and similarity measures and some of their applications. The concept of possibility soft sets is introduced as the generalization of soft sets. Alkhazaleh et al. [20] introduced the possibility fuzzy soft sets. Further, Bashir et al. [21] proposed the idea of the possibility intuitionistic fuzzy soft sets. Later, Karaaslan [22] defined the possibility neutrosophic soft sets. Researchers have also discussed the operations and applications of possibility soft sets. As a result of the earlier studies, the theory of Possibility Plithogenic Soft Sets has been developed as an extension of Plithogenic Soft sets. Moreover, this paper presents a theoretical framework of the Possibilityplithogenic hesitant fuzzy soft sets, some of their properties and a decision making framework.

PRELIMINARIES

In this section, we will review some of the fundamental definitions required to read this paper.

Definition 2.1 [4]

A pair (F, E) is called a soft set (over U) if and only if F is a mapping of E into the set of all subsets of the set U. In other words, the soft set is a parameterized family of subsets of the set U. Every set $F(\varepsilon), \varepsilon \in E$, from this family may be considered as the set of ε- elements of the soft set (F, E), or as the set of ε - approximate elements of the soft set.

Definition 2.2 [5]

A fuzzy soft set over U is a pair (F, A), where $F: A \rightarrow P(U)$ is a mapping from A into $P(U)$.

Definition 2.3 [14]

If X is a fixed set, then a Hesitant Fuzzy Set (HFS) on X is defined in terms of a function $h_M(x)$ that returns a subset of[0,1], when it is applied to X. This can be represented using the following expression $M = \{< x, h_M(x) > \mid x \in X\}$, where $h_M(x)$ is a set of values in [0,1] that represent the various membership degrees of the element $x \in X$ to the set M. We refer to $h = h_M(x)$ as a hesitant fuzzy element (HFE) for simplicity, and H is the set of all HFEs.

Definition 2.4 [16]
Let U be a universal set and E be set of parameters. Let HF(U) denotes the set of all hesitant fuzzy sets defined over U. A pair *(F,E)* is a hesitant fuzzy soft set if *F(e)* ∈ *HF(U)* for every *e* in *E*.

Definition 2.5 [17]
Let U be the discourse universe and P be the non-empty set of elements, such that $P \subseteq U$. Then, *a* is an attribute (generally multidimensional), *V* is the range of the attribute values, *d* is the degree to which each element *x*'s attribute value belongs to the set P in relation to a given set of criteria *(x ∈ P)*, and *c* is the degree of contradictionbetween attribute values. Then, *(P, a, V, d, c)* is called a plithogenic set.

Definition 2.6 [18]
Assume that U is a discourse universe and that $(U)^z$ is the z-power set of U such that
$z = C$ (Power set of U),
$z = F$ (The set of all fuzzy sets of U),
$z = IF$ (The set of all intuitionistic fuzzy sets of U), or
$z = N$ (The set of all neutrosophic sets of U).
Let $a_1, a_2, \cdots, a_n$, for $n \geq 1$, be n distinct attributes, where corresponding attribute values $V_1, V_2, \cdots, V_n$, with $Vi \cap Vj = \emptyset$,for $j \neq i$, and $i, j \in \{1, 2, \cdots, n\}$. Suppose $V_i = \{v_{i_1}, v_{i_2}, \cdots, v_{i_{mi}}\}$and let$\Upsilon = V_1 \times V_2 \times \cdots \times V_n$.Let$c\left(D_i, v_{ij}\right)$, $i \in \{1,2, \cdots n\}, j \in \{1,2, \cdots m_i\}$ be the attribute value contradiction degree such that $c_i: V_i \times V_i \to [0,1]$,and let $D = (D_1, D_2, \cdots D_n)$ the dominant attribute element of $V_i, \forall i$. Then the pair (F_P^Z, Υ), where$F_P^Z: \Upsilon \to [0,1]_D \times (U)^z$ is called a Plithogenic Soft Set (P-SS In short) over U.

Definition 2.7 [19]
Let U be a universe of discourse, $(U)^H$the power set of U such that H is the set of all Hesitant fuzzy soft sets. Let $a_1, a_2, \cdots, a_n$, for $n \geq 1$,be n distinct attributes, whose corresponding attribute values are respectively the sets $V_1, V_2, \cdots, V_n$, with $Vi \cap Vj = \emptyset$, , for $j \neq i$, and $i, j \in \{1,2, \cdots, n\}$. Suppose $V_i = \{v_{i_1}, v_{i_2}, \cdots, v_{i_{mi}}\}$and let $\mathcal{H} = V_1 \times V_2 \times \cdots \times V_n$.Let$D = (D_1, D_2, \cdots D_n)$thedominantattributeelementof V_i, $\forall i$ and$c\left(D_i, v_{ij}\right)$, where$i \in \{1, 2, \cdots n\}$, $j \in \{1,2, \cdots m_i\}$theattributevaluecontradictiondegreefunctionsuchthat $c_i: V_i \times V_i \to [0,1]$. Then the pair$\left(\mathrm{F_P^H}, \mathcal{H}\right)$, where$F_P^H : \mathcal{H} \to [0,1]_D \times (U)^H$ is called a Plithogenic hesitant fuzzy soft set (P-HFSS In short) over U.

Definition 2.8 [23]
According to the Definition 2.6 [18] , A Possibility Plithogenic soft set over U is a set of ordered pairs of the form (F_{PP}^z, Υ) defined by $F_P^z: \Upsilon \to [0,1]_D \times (U)^z \times (I)^z$,where $(I)^z$is the collection of all fuzzy subsets of U.

Definition 2.9 [23]
Let (F_{PP}^z, H) and (G_{PP}^z, H) be two Possibility Plithogenic soft sets.The similarity measure between (F_{PP}^z, H) and (G_{PP}^z, H) is defined by $S_P(F_{PP}^z, G_{PP}^z) = M\left(F_{PP}^z(e), G_{PP}^z(e)\right) * M\left(\mu_{F_{PP}^z}(e), \mu_{G_{PP}^z}(e)\right)$,where

$$M\left(F_{PP}^z(e), G_{PP}^z(e)\right) = \max_k M_k\left(F_{PP}^z(e), G_{PP}^z(e)\right)$$

$$M\left(\mu_{F_{PP}}(e), \mu_{G_{PP}^z}(e)\right) = \max_k M_k\left(\mu_{F_{PP}}(e), \mu_{G_{PP}}(e)\right)$$

$$M_k\left(F_{PP}^z(e), G_{PP}^z(e)\right) = 1 - \frac{\sum_{j=1}^{|U|}\sum_{i=1}^{|e|}\left|\left(F_j(e_{ik})\right) - \left(G_j(e_{ik})\right)\right|}{\sum_{j=1}^{|U|}\sum_{i=1}^{|e|}\left|\left(F_j(e_{ik})\right) + \left(G_j(e_{ik})\right)\right|},$$

$$M_k\left(\mu_{F_{PP}}(e), \mu_{G_{PP}}(e)\right) = 1 - \frac{\sum_{j=1}^{|U|}\sum_{i=1}^{|e|}\left|\left(\mu_{F_{PP}}(e_{ik})\right) - \mu_{G_{PP}}\left(G_j(e_{ik})\right)\right|}{\sum_{j=1}^{|U|}\sum_{i=1}^{|e|}\left|\left(\mu_{F_{PP}}(e_{ik})\right) + \mu_{G_{PP}}\left(G_j(e_{ik})\right)\right|}.$$

Possibility Plithogenic Hesitant Fuzzy Soft set
In this section we define the Possibility Plithogenic hesitant fuzzy soft set and some of its properties.

Definition 3.1

Let U be a universe of discourse, $(U)^H$be the power set of U such that H is the set of all hesitant fuzzy soft sets. Assume$a_1, a_2, \cdots, a_n$, for $n \geq 1$, be n distinct attributes, whose corresponding attribute values are $V_1, V_2, \cdots, V_n$ respectively with $V_i \cap V_j = \emptyset$, for $j \neq i$, and $i, j \in \{1,2, \cdots, n\}$. Suppose$V_i = \{v_{i_1}, v_{i_2}, \cdots, v_{i_{mi}}\}$ and$\mathcal{H} = V_1 \times V_2 \times \cdots \times V_n$. Let the dominant attributeelement of $V_i$be $D = (D_1, D_2, \cdots D_n), \forall i$ and $c(D_i, v_{ij})$, where$i \in \{1,2, \cdots n\}, j \in \{1,2, \cdots m_i\}$be the attribute value contradiction degree function suchthat $c_i: V_i \times V_i \to [0,1]$. A Possibility Plithogenic hesitant fuzzy soft set (PP-HFSS) over U is the set of ordered pairs$(F_{PP}^H, \mathcal{H})$, defined by $F_{PP}^H: \mathcal{H} \to [0,1]_D \times (U)^H \times (\mathrm{I})^{\mathrm{H}}$, where $(I)^H$is the collection of all fuzzy subsets of U.

Example 3.2

Consider an example on selection of agriculture land.Let $U = \{L_1, L_2, L_3, L_4\}$ be the set of lands with the attributes a_1 = Budget(Cost),a_2 = Quality of the soil, a_3 =Water facilityand their corresponding attribute values Budget $\equiv \mathrm{A}_1 =$ { Low , Avg ,High }, Quality of the soil$\equiv \mathrm{A}_2 =$ {Good,Avg,Bad}, Water facility$\equiv \mathrm{A}_3 =$ {Good,Above avg,Low},here $D =$ (Low, Good, Above avg) be the dominant attribute values.Let $\mathrm{E} \subseteq \mathcal{H}$ such that $\mathrm{E} =$ {$\varepsilon_1 =$ (Low, avg,Low), $\varepsilon_2 =$ (High,Good ,Above avg), $\varepsilon_3 =$ (Low, Avg , Good) }.

Then,

$$F_{PP}^H(\varepsilon_1) = \left\{ \frac{(\mathrm{L}_1, (0,0.5,0.4,0.9)_{\mathrm{D}})}{\{(0.2,0.4),(0,0.5),(0.2,0.3,0.6),(0.2,0.6,0.8)\}}, 0.6, \frac{(\mathrm{L}_2, (0,0.5,0.4,0.9)_{\mathrm{D}})}{\{(0.6,0.7,0.8),(0,1),(0.6,0.7),(0.8,0.9,1)\}}, 0.4, \frac{(\mathrm{L}_3, (0,0.5,0.4,0.9)_{\mathrm{D}})}{\{(0.4,0.5),(0.2,0.3,0.4),(0.2,0.1),(0.7,0.9)\}}, 0.3, \frac{(\mathrm{L}_4, (0,0.5,0.4,0.9)_{\mathrm{D}})}{\{(0.7,0.9),(0.5,0.6,1),(0.8,0.9),(0.3,0.6,0.7)\}}, 0.7 \right\}$$

$$F_{PP}^H(\varepsilon_2) = \left\{ \frac{(\mathrm{L}_1, (0.8,0.4,0.5,0.7)_{\mathrm{D}})}{\{(0.2,0.3),(0,1),(0.6,0.7),(0.9,1)\}}, 0.2, \frac{(\mathrm{L}_2, (0.8,0.4,0.5,0.7)_{\mathrm{D}})}{\{(0.5,0.6,1),(0.5,1),(0.9,1),(0,0.2)\}}, 0.6, \frac{(\mathrm{L}_3, (0.8,0.4,0.5,0.7)_{\mathrm{D}})}{\{(0.2,0.3),(0.6,1),(0,0.5),(0.7,0.8,0.9)\}}, 0.4, \frac{(\mathrm{L}_4, (0.8,0.4,0.5,0.7)_{\mathrm{D}})}{\{(0.9,1),(0,0.5,1),(0.7,0.9),(0.6,0.7)\}}, 0.8 \right\}$$

$$F_{PP}^H(\varepsilon_3) = \left\{ \frac{(\mathrm{L}_1, (0,0.5,0.6,1)_{\mathrm{D}})}{\{(0.5,0.7,1),(0.6,0.9),(0,0.2),(0.9,1)\}}, 0.3, \frac{(\mathrm{L}_2, (0,0.5,0.6,1)_{\mathrm{D}})}{\{(0.2,0.7),(0.3,0.9),(0,0.2,1),(0.7,0.8,0.9)\}}, 0.6, \frac{(\mathrm{L}_3, (0,0.5,0.6,1)_{\mathrm{D}})}{\{(0.1,0.4),(0.6,,0.8,1),(0.3,0.5),(0.6,0.8)\}}, 0.5, \frac{(\mathrm{L}_4, (0,0.5,0.6,1)_{\mathrm{D}})}{\{(0.6,0.9),(0.5,0.6,0.9),(0.2,0.3),(0,0.5)\}}, 0.4 \right\}$$

Then we have the PP- HFSS as follows :

$$(F_{PP}^H, E) = \left\{ \varepsilon_1, \left\{ \frac{(\mathrm{L}_1, (0,0.5,0.4,0.9)_{\mathrm{D}})}{\{(0.2,0.4),(0,0.5),(0.2,0.3,0.6),(0.2,0.6,0.8)\}}, 0.6, \frac{(\mathrm{L}_2, (0,0.5,0.4,0.9)_{\mathrm{D}})}{\{(0.6,0.7,0.8),(0,1),(0.6,0.7),(0.8,0.9,1)\}}, 0.4, \frac{(\mathrm{L}_3, (0,0.5,0.4,0.9)_{\mathrm{D}})}{\{(0.4,0.5),(0.2,0.3,0.4),(0.2,0.1),(0.7,0.9)\}}, 0.3, \frac{(\mathrm{L}_4, (0,0.5,0.4,0.9)_{\mathrm{D}})}{\{(0.7,0.9),(0.5,0.6,1),(0.8,0.9),(0.3,0.6,0.7)\}}, 0.7 \right\} \right.$$

$$\varepsilon_2, \left\{ \frac{(\mathrm{L}_1, (0.8,0.4,0.5,0.7)_{\mathrm{D}})}{\{(0.2,0.3),(0,1),(0.6,0.7),(0.9,1)\}}, 0.2, \frac{(\mathrm{L}_2, (0.8,0.4,0.5,0.7)_{\mathrm{D}})}{\{(0.5,0.6,1),(0.5,1),(0.9,1),(0,0.2)\}}, 0.6, \frac{(\mathrm{L}_3, (0.8,0.4,0.5,0.7)_{\mathrm{D}})}{\{(0.2,0.3),(0.6,1),(0,0.5),(0.7,0.8,0.9)\}}, 0.4, \frac{(\mathrm{L}_4, (0.8,0.4,0.5,0.7)_{\mathrm{D}})}{\{(0.9,1),(0,0.5,1),(0.7,0.9),(0.6,0.7)\}}, 0.8 \right\},$$

$$\left. \varepsilon_3, \left\{ \frac{(\mathrm{L}_1, (0,0.5,0.6,1)_{\mathrm{D}})}{\{(0.5,0.7,1),(0.6,0.9),(0,0.2),(0.9,1)\}}, 0.3, \frac{(\mathrm{L}_2, (0,0.5,0.6,1)_{\mathrm{D}})}{\{(0.2,0.7),(0.3,0.9),(0,0.2,1),(0.7,0.8,0.9)\}}, 0.6, \frac{(\mathrm{L}_3, (0,0.5,0.6,1)_{\mathrm{D}})}{\{(0.1,0.4),(0.6,0.8,1),(0.3,0.5),(0.6,0.8)\}}, 0.5, \frac{(\mathrm{L}_4, (0,0.5,0.6,1)_{\mathrm{D}})}{\{(0.6,0.9),(0.5,0.6,0.9),(0.2,0.3),(0,0.5)\}}, 0.4 \right\} \right\}$$

The matrix representation of the above PP- HFSS is as follows:

$$[F_{PP}^H(\rho_1)] = \begin{bmatrix} ((0.2,0.4),0.6) & ((0.6,0.7,0.8),0.4) & ((0.4,0.5),0.3) & ((0.7,0.9),0.7) \\ ((0.2,0.3),0.2) & ((0.5,0.6,1),0.6) & ((0.2,0.3,0.4),0.4) & ((0.9,1),0.8) \\ ((0.5,0.7,1),0.3) & ((0.2,0.7),0.6) & ((0.1,0.4),0.5) & ((0.6,0.9),0.4) \end{bmatrix}$$

$$[F_{PP}^{H}(\rho_2)] = \begin{bmatrix} ((0,0.5),0.6) & ((0,1),0.4) & ((0.2,0.1),0.3) & ((0.5,0.6,1),0.7) \\ ((0,1),0.2) & ((0.5,1),0.6) & ((0.6,0.1),0.4) & ((0,0.5,1)),0.8) \\ ((0.6,0.9),0.3) & ((0.3,0.9),0.6) & ((0.6,0.8,1),0.5) & ((0.5,0.6,0.9),0.4) \end{bmatrix}$$

$$[F_{PP}^{H}(\rho_3)] = \begin{bmatrix} ((0.2,0.1),0.6) & ((0.8,0.9),0.4) & ((0.4,0.5),0.3) & ((0.8,0.9),0.7) \\ ((0.6,0.7),0.2) & ((0.7,0.9),0.6) & ((0,0.5),0.4) & ((0.7,0.9),0.8) \\ ((0,0.2),0.3) & ((0,0.2,0.6)) & ((0.3,0.5),0.5) & ((0.2,0.3),0.4) \end{bmatrix}$$

$$[\mathrm{F_{PP}^{H}}(\rho_4)] = \begin{bmatrix} ((0.2,0.6,0.8),0.6) & ((0.8,0.9,1),0.4) & ((0.7,0.9),0.3) & ((0.3,0.6,0.7),0.7) \\ ((0.9,1),0.2) & ((0,0.2),0.6) & ((0.7,0.8,0.9),0.4) & ((0.6,0.7),0.8) \\ ((0.9,1),0.3) & ((0.7,0.8,0.9),0.6) & ((0.6,0.8),0.5) & ((0,0.5),0.4) \end{bmatrix}$$

Definition 3.3

The union of two PP-HFSSs(F_{PP}^{H}, A) and (G_{PP}^{H}, B) over U , denoted by$(J_{PP}^{H}, C) = (F_{P}^{H}, A) \vee_{P}^{H} (G_{P}^{H}, B)$ is defined by the function $J: \mathcal{H} \to [0,1]_D \times (U)^H \times (I)^H$suchthat $(J_{PP}^{H}, C)(\varepsilon) = (F_{PP}^{H}, A)(\varepsilon) \cup (G_{PP}^{H}, B)(\varepsilon), \forall\, \varepsilon \in E \subseteq \mathcal{H}$.

Example 3.4

$$\text{Let}(F_{PP}^{H}, A) = \left\{ \varepsilon_1, \left\{ \frac{(\mathrm{L}_1,(0,0.3,0.2)_{\mathrm{D}})}{\{(0.2,0.4),(0,0.5),(0.2,0.3,0.5)\}}, 0.6, \frac{(\mathrm{L}_2,(0,0.3,0.2)_{\mathrm{D}})}{\{(0.6,0.7,0.8),(0.2,1),(0.6,0.7)\}}, 0.4, \frac{(\mathrm{L}_3,(0,0.3,0.2)_{\mathrm{D}})}{\{(0.4,0.5),(0.2,0.3,0.4),(0.2,0.1)\}}, 0.3 \right\}, \right.$$
$$\left. \varepsilon_2, \left\{ \frac{(\mathrm{L}_1,(0.7,0.3,0.6)_{\mathrm{D}})}{\{(0.2,0.6,0.8),(0,1),(0.6,0.7)\}}, 0.2, \frac{(\mathrm{L}_2,(0.7,0.3,0.6)_{\mathrm{D}})}{\{(0.5,0.6,1),(0.5,1),(0.9,1)\}}, 0.6, \frac{(\mathrm{L}_3,(0.7,0.3,0.6)_{\mathrm{D}})}{\{(0.2,0.3),(0.6,1),(0,0.5)\}}, 0.4 \right\} \right\}$$

$$\text{and}(G_{PP}^{H}, B) = \left\{ \varepsilon_1, \left\{ \frac{(\mathrm{L}_1,(0,0.3,0.2)_{\mathrm{D}})}{\{(0.3,0.5),(0.2,0.6),(0.3,0.4,0.6)\}}, 0.4, \frac{(\mathrm{L}_2,(0,0.3,0.2)_{\mathrm{D}})}{\{(0.3,0.5,0.7),(0,0.5),(0.7,0.8)\}}, 0.6, \frac{(\mathrm{L}_3,(0,0.3,0.2)_{\mathrm{D}})}{\{(0.5,0.8),(0,0.5,1),(0,0.5)\}}, 0.5 \right\}, \right.$$
$$\left. \varepsilon_2, \left\{ \frac{(\mathrm{L}_1,(0.7,0.3,0.6)_{\mathrm{D}})}{\{(0.4,0.7,0.9),(0,1),(0.7,0.9)\}}, 0.3, \frac{(\mathrm{L}_2,(0.7,0.3,0.6)_{\mathrm{D}})}{\{(0.2,0.4,0.6),(0.5,1),(0.7,0.9)\}}, 0.7, \frac{(\mathrm{L}_3,(0.7,0.3,0.6)_{\mathrm{D}})}{\{(0.5,0.7),(0.5,0.9),(0.6,0.8)\}}, 0.6 \right\} \right\}$$

be PP-HFSSs. Then by using fuzzy union (maximum), the union of two PP-HFSSs is obtained as

$$(\mathrm{J_{PP}^{H}}, C) = \left\{ \varepsilon_1, \left\{ \frac{(\mathrm{L}_1,(0,0.3,0.2)_{\mathrm{D}})}{\{(0.3,0.5),(0.14,0.57),(0.28,0.38,0.58)\}}, 0.6, \frac{(\mathrm{L}_2,(0,0.3,0.2)_{\mathrm{D}})}{\{(0.6,0.7,0.8),(0.14,0.85),(0.68,0.78)\}}, 0.6, \frac{(\mathrm{L}_3,(0,0.3,0.2)_{\mathrm{D}})}{\{(0.5,0.8),(0.06,0.44,0.82),(0.16,0.80)\}}, 0.5 \right\}, \right.$$
$$\left. \varepsilon_2, \left\{ \frac{(\mathrm{L}_1,(0.7,0.3,0.6)_{\mathrm{D}})}{\{(0.26,0.63,0.83),(0,1),(0.62,0.74)\}}, 0.3, \frac{(\mathrm{L}_2,(0.7,0.3,0.6)_{\mathrm{D}})}{\{(0.29,0.46,0.72),(0.5,1),(0.74,0.92)\}}, 0.7, \frac{(\mathrm{L}_3,(0.7,0.3,0.6)_{\mathrm{D}})}{\{(0.29,0.42),(0.54,0.94),(0.12,0.56)\}}, 0.6 \right\} \right\},$$

where the possibility degree is determined using max operator.

Definition 3.5

The intersection of two PP-HFSSs(F_{PP}^{H}, A) and (G_{PP}^{H}, B) over U , denoted by$(K_{PP}^{H}, C) = (F_{P}^{H}, A) \vee_{P}^{H} (G_{P}^{H}, B)$ is defined by the function $J: \mathcal{H} \to [0,1]_D \times (U)^H \times (I)^H$suchthat $(K_{PP}^{H}, C)(\varepsilon) = (F_{PP}^{H}, A)(\varepsilon) \cap (G_{PP}^{H}, B)(\varepsilon), \forall\, \varepsilon \in E \subseteq \mathcal{H}$.

Example 3.6

Consider the Example 3.4.By using fuzzy intersection (minimum), the intersection of two PP-HFSSs is obtained as

$$\left(\mathrm{K}_{\mathrm{PP}}^{\mathrm{H}}, C\right)=\left\{\begin{array}{l}\varepsilon_1,\left\{\begin{array}{c}\frac{\left(\mathrm{L}_1,(0,0.3,0.2)_{\mathrm{D}}\right)}{\{(0.2,0.4),(0.06,0.53),(0.22,0.32,0.52)\}}, 0.4, \frac{\left(\mathrm{L}_2,(0,0.3,0.2)_{\mathrm{D}}\right)}{\{(0.3,0.5,0.7),(0.06,0.65),(0.62,0.72)\}}, 0.4, \\ \frac{\left(\mathrm{L}_3,(0,0.3,0.2)_{\mathrm{D}}\right)}{\{(0.4,0.5),(0.14,0.36,0.58),(0.04,0.60)\}}, 0.3\end{array}\right\}, \\ \varepsilon_2,\left\{\begin{array}{c}\frac{\left(\mathrm{L}_1,(0.7,0.3,0.6)_{\mathrm{D}}\right)}{\{(0.34,0.67,0.87),(0,1),(0.68,0.86)\}}, 0.2, \frac{\left(\mathrm{L}_2,(0.7,0.3,0.6)_{\mathrm{D}}\right)}{\{(0.41,0.54,0.88),(0.5,1),(0.86,0.98)\}}, 0.6, \\ \frac{\left(\mathrm{L}_3,(0.7,0.3,0.6)_{\mathrm{D}}\right)}{\{(0.41,0.58),(0.56,0.96),(0.48,0.74)\}}, 0.4\end{array}\right\}\end{array}\right\},$$

where the possibility degree is determined using min operator.

Definition 3.7

Let (F_{PP}^H, I) and (G_{PP}^H, I) be two PP-HFSSs.The similarity measure between (F_{PP}^H, I) and (G_{PP}^H, I) is defined by $S_P(F_{PP}^H, G_{PP}^H) = M\left(F_{PP}^H(e), G_{PP}^H(e)\right) * M\left(\mu_{F_{PP}^H}(e), \mu_{G_{PP}^H}(e)\right)$,where$H$ represents the set of all hesitant fuzzy soft sets and

$$M\left(F_{PP}^H(e), G_{PP}^H(e)\right) = \max_k M_k\left(F_{PP}^H(e), G_{PP}^H(e)\right)$$

$$M\left(\mu_{F_{PP}^H}(e), \mu_{G_{PP}^H}(e)\right) = \max_k M_k\left(\mu_{F_{PP}^H}(e), \mu_{G_{PP}^H}(e)\right)$$

$$M_k\left(F_{PP}^H(e), G_{PP}^H(e)\right) = 1 - \frac{\sum_{j=1}^{|U|}\sum_{i=1}^{|e|}\left|\left(F_j(e_{ik})\right) - \left(G_j(e_{ik})\right)\right|}{\sum_{j=1}^{|U|}\sum_{i=1}^{|e|}\left|\left(F_j(e_{ik})\right) + \left(G_j(e_{ik})\right)\right|}$$

$$M_k\left(\mu_{F_{PP}^H}(e), \mu_{G_{PP}^H}(e)\right) = 1 - \frac{\sum_{j=1}^{|U|}\sum_{i=1}^{|e|}\left|\left(\mu_{F_{PP}}(e_{ik})\right) - \mu_{G_{PP}}\left(G_j(e_{ik})\right)\right|}{\sum_{j=1}^{|U|}\sum_{i=1}^{|e|}\left|\left(\mu_{F_{PP}}(e_{ik})\right) + \mu_{G_{PP}}\left(G_j(e_{ik})\right)\right|}.$$

A Decision Making approach in Possibility Plithogenic Hesitant Fuzzy Soft sets

Consider a situation that,a person wants to build a new house,so he approches four different engineers where each engineer offers four different construction packages. So that he can easily choose the engineer with the best package.Let $U = \{P_1, P_2, P_3, P_4\}$represents the set of packageswith the distinct attributes a_1 = Budget(Cost), a_2 = Design,a_3 = Completion period and their corresponding attribute values are Budget≡ A_1 = {Low, Avg ,High },Design≡ A_2 = {Luxury, Modern house, Traditional house}, Completion period ≡ A_3 = { Short term, Medium, Long term}, here D = (Low, Modern house, Medium) denotes the dominant attribute values.Let $E \subseteq \mathcal{H}$ such that $E = \{\varepsilon_1 =$ (Avg, Modern house, Long term), $\varepsilon_2 =$ (High, ,Traditional house, Long term)}.

The expected packages with respect to the set of attribute values are expressed in PP-HFSS as follows:

$$(F_{PP}^H, E) = \left\{\begin{array}{l}\varepsilon_1,\left\{\begin{array}{c}\frac{\left(\mathrm{P}_1,(0,0.5,1)_{\mathrm{D}}\right)}{\left\{\binom{0.5,0.}{8}, (0.7,0.9,1), (0.2,0.3)\right\}}, 0.6, \frac{\left(\mathrm{P}_2,(0,0.5,1)\right.}{\{(0.7,0.8),(0.9,1),(0.5,0.6)\}}, 0.8, \\ \frac{\left(\mathrm{P}_3,(0,0.5,1)_{\mathrm{D}}\right)}{\{(0.8,1),(0.2,0.5),(0.2,0.3,0.7)\}}, 0.7, \frac{\left(\mathrm{P}_4,(0,0.5,1)_{\mathrm{D}}\right)}{\{(0.2,0.4),(0.3,0.8),(0.3,0.6,0.7)\}}, 0.5\end{array}\right\}, \\ \varepsilon_2,\left\{\begin{array}{c}\frac{\left(\mathrm{P}_1,(0.2,0.5,1)_{\mathrm{D}}\right)}{\{(0.6,0.7),(0.9,1),(0.5,0.6)\}}, 0.6, \frac{\left(\mathrm{P}_2,(0.2,0.5,1)_{\mathrm{D}}\right)}{\{(0.5,1),(0.3,0.9),(0.8,0.9)\}}, 0.7, \\ \frac{\left(\mathrm{P}_3,(0.2,0.5,1)_{\mathrm{D}}\right)}{\{(0.3,0.5),(0.3,0.7),(0.3,0.7,0.8)\}}, 0.8, \frac{\left(\mathrm{P}_4,(0.2,0.5,1)_{\mathrm{D}}\right)}{\{(0.7,0.9),(0.3,0.6),(0.1,0.4)\}}, 0.4\end{array}\right\}\end{array}\right\}$$

The person receives packages from different engineers and they are represented as PP- HFSS:

$$(E1_{PP}^H, E) = \left\{\begin{array}{l}\varepsilon_1,\left\{\begin{array}{c}\frac{\left(\mathrm{P}_1,(0,0.5,1)_{\mathrm{D}}\right)}{\{(0.2,0.3),(0.5,0.6,0.7),(0.4,0.7)\}}, 0.6, \frac{\left(\mathrm{P}_2,(0,0.5,1)\right.}{\{(0.6,0.7),(0.8,0.9),(0,1)\}}, 0.5, \\ \frac{\left(\mathrm{P}_3,(0,0.5,1)_{\mathrm{D}}\right)}{\{(0.9,1),(0.6,0.7),(0,0.2,0.3)\}}, 0.7, \frac{\left(\mathrm{P}_4,(0,0.5,1)_{\mathrm{D}}\right)}{\{(0,0.5),(0.1,0.7),(0.8,0.9,1)\}}, 0.8\end{array}\right\}, \\ \varepsilon_2,\left\{\begin{array}{c}\frac{\left(\mathrm{P}_1,(0.2,0.5,1)_{\mathrm{D}}\right)}{\{(0.5,0.6),(0.7,0.8),(0,1)\}}, 0.6, \frac{\left(\mathrm{P}_2,(0.2,0.5,1)_{\mathrm{D}}\right)}{\{(0.6,0.7),(0.4,0.7),(0.9,1)\}}, 0.5, \\ \frac{\left(\mathrm{P}_3,(0.2,0.5,1)_{\mathrm{D}}\right)}{\{(0,1),(0.2,0.6),(0.7,0.9,1)\}}, 0.6, \frac{\left(\mathrm{P}_4,(0.2,0.5,1)_{\mathrm{D}}\right)}{\{(0.5,0.6),(0.7,0.8),(0.9,1)\}}, 0.8\end{array}\right\}\end{array}\right\}$$

$$(E2_{PP}^{H},E)=\left\{\varepsilon_1,\left\{\frac{(P_1,(0,0.5,1)_D)}{\{(0.5,1),(0.2,0.4),(0.6,0.7,0.8)\}},0.6,\frac{(P_2,(0,0.5,1)}{\{(0,1),(0.7,0.9),(0.6,0.7,0.9)\}},0.8,\frac{(P_3,(0,0.5,1)_D)}{\{(0.2,0.9),(0.6,0.7),(0.5,0.6)\}},0.4,\frac{(P_4,(0,0.5,1)_D)}{\{(0.6,0.7),(0.8,0.9),(0,1)\}},0.3\right\},\right.$$
$$\left.\varepsilon_2,\left\{\frac{(P_1,(0.2,0.5,1)_D)}{\{(0,0.6),(0.7,0.9,1),(0.2,0.3)\}},0.6,\frac{(P_2,(0.2,0.5,1)_D)}{\{(0.8,1),(0.5,1),(0.9,1)\}},0.6,\frac{(P_3,(0.2,0.5,1)_D)}{\{(0.5,0.6),(0.8,0.9,1),(0.2,0.7)\}},0.7,\frac{(P_4,(0.2,0.5,1)_D)}{\{(0.6,0.7),(0.5,1),(0.6,0.9)\}},0.9\right\}\right\}$$

$$(E3_{PP}^{H},E)=\left\{\varepsilon_1,\left\{\frac{(P_1,(0,0.5,1)_D)}{\{(0.5,0.6),(0.7,0.9),(0.2,0.3)\}},0.5,\frac{(P_2,(0,0.5,1)}{\{(0.3,0.4,0.6),(0.2,0.3),(0,0.5)\}},0.8,\frac{(P_3,(0,0.5,1)_D)}{\{(0.9,1),(0.2,1),(0,0.5,1)\}},0.2,\frac{(P_4,(0,0.5,1)_D)}{\{(0.2,0.4,0.6),(0.3,0.5),(0.6,0.9)\}},0.6\right\},\right.$$
$$\left.\varepsilon_2,\left\{\frac{(P_1,(0.2,0.5,1)_D)}{\{(0.6,0.9,1),(0.2,0.4),(0.5,1)\}},0.4,\frac{(P_2,(0.2,0.5,1)_D)}{\{(0.2,0.3),(0.4,0.5,1),(0.7,0.9)\}},0.5,\frac{(P_3,(0.2,0.5,1)_D)}{\{(0.5,0.6),(0.7,0.9,1),(0,1)\}},0.8,\frac{(P_4,(0.2,0.5,1)_D)}{\{(0.9,1),(0,0.2),(0.3,0.4,0.5)\}},0.6\right\}\right\}$$

$$(E4_{PP}^{H},E)=\left\{\varepsilon_1,\left\{\frac{(P_1,(0,0.5,1)_D)}{\{(0.6,0.7),(0.5,0.8),(0,0.2)\}},0.3,\frac{(P_2,(0,0.5,1)}{\{(0.9,1),(0.6,0.8,0.9),(0,0.4)\}},0.5,\frac{(P_3,(0,0.5,1)_D)}{\{(0.2,0.3),(0.4,0.5),(0.7,0.9)\}},0.8,\frac{(P_4,(0,0.5,1)_D)}{\{(0.6,0.7),(0.5,1),\binom{0.6,0}{7,0.8}\}},0.6\right\},\right.$$
$$\left.\varepsilon_2,\left\{\frac{(P_1,(0.2,0.5,1)_D)}{\{(0.4,0.5),(0,0.2,0.3),(0.6,0.9)\}},0.4,\frac{(P_2,(0.2,0.5,1)_D)}{\{(0.8,1),(0.2,1),(0.5,0.8)\}},0.6,\frac{(P_3,(0.2,0.5,1)_D)}{\{(0.9,1),(0.6,0.7,1),(0.4,0.6)\}},0.7,\frac{(P_4,(0.2,0.5,1)_D)}{\{(0.6,0.8,0.9),(0.3,0.7),(0.6,0.9)\}},0.5\right\}\right\}$$

The similarity measure betweenexpected packages and the received packages from different engineers in PP-HFSS are given in Table 1.

The expected packages are representedinP-HFSS as follows:

$$(F_P^{H},E)=\left\{\varepsilon_1,\left\{\frac{(P_1,(0,0.5,1)_D)}{\left\{\binom{0.5,0.}{8},(0.7,0.9,1),(0.2,0.3)\right\}},\frac{(P_2,(0,0.5,1)}{\{(0.7,0.8),(0.9,1),(0.5,0.6)\}},\frac{(P_3,(0,0.5,1)_D)}{\{(0.8,1),(0.2,0.5),(0.2,0.3,0.7)\}},\frac{(P_4,(0,0.5,1)_D)}{\{(0.2,0.4),(0.3,0.8),(0.3,0.6,0.7)\}}\right\},\right.$$
$$\left.\varepsilon_2,\left\{\frac{(P_1,(0.2,0.5,1)_D)}{\{(0.6,0.7),(0.9,1),(0.5,0.6)\}},\frac{(P_2,(0.2,0.5,1)_D)}{\{(0.5,1),(0.3,0.9),(0.8,0.9)\}},\frac{(P_3,(0.2,0.5,1)_D)}{\{(0.3,0.5),(0.3,0.7),(0.3,0.7,0.8)\}},\frac{(P_4,(0.2,0.5,1)_D)}{\{(0.7,0.9),(0.3,0.6),(0.1,0.4)\}},\right\}\right\}$$

The packages received from different engineers are expressed in P-HFSS as follows:

$$(E1_P^{H},E)=\left\{\varepsilon_1,\left\{\frac{(P_1,(0,0.5,1)_D)}{\{(0.2,0.3),(0.5,0.6,0.7),(0.4,0.7)\}},\frac{(P_2,(0,0.5,1)}{\{(0.6,0.7),(0.8,0.9),(0,1)\}},\frac{(P_3,(0,0.5,1)_D)}{\{(0.9,1),(0.6,0.7),(0,0.2,0.3)\}},\frac{(P_4,(0,0.5,1)_D)}{\{(0,0.5),(0.1,0.7),(0.8,0.9,1)\}}\right\},\right.$$
$$\left.\varepsilon_2,\left\{\frac{(P_1,(0.2,0.5,1)_D)}{\{(0.5,0.6),(0.7,0.8),(0,1)\}},\frac{(P_2,(0.2,0.5,1)_D)}{\{(0.6,0.7),(0.4,0.7),(0.9,1)\}},\frac{(P_3,(0.2,0.5,1)_D)}{\{(0,1),(0.2,0.6),(0.7,0.9,1)\}},\frac{(P_4,(0.2,0.5,1)_D)}{\{(0.5,0.6),(0.7,0.8),(0.9,1)\}}\right\}\right\}$$

$$(E2_P^H, E) = \left\{ \varepsilon_1, \left\{ \begin{matrix} \frac{(P_1,(0,0.5,1)_D)}{\{(0.5,1),(0.2,0.4),(0.6,0.7,0.8)\}}, \frac{(P_2,(0,0.5,1)}{\{(0,1),(0.7,0.9),(0.6,0.7,0.9)\}}, \\ \frac{(P_3,(0,0.5,1)_D)}{\{(0.2,0.9),(0.6,0.7),(0.5,0.6)\}}, \frac{(P_4,(0,0.5,1)_D)}{\{(0.6,0.7),(0.8,0.9),(0,1)\}} \end{matrix} \right\}, \right.$$
$$\left. \varepsilon_2, \left\{ \begin{matrix} \frac{(P_1,(0.2,0.5,1)_D)}{\{(0,0.6),(0.7,0.9,1),(0.2,0.3)\}}, \frac{(P_2,(0.2,0.5,1)_D)}{\{(0.8,1),(0.5,1),(0.9,1)\}}, \\ \frac{(P_3,(0.2,0.5,1)_D)}{\{(0.5,0.6),(0.8,0.9,1),(0.2,0.7)\}}, \frac{(P_4,(0.2,0.5,1)_D)}{\{(0.6,0.7),(0.5,1),(0.6,0.9)\}} \end{matrix} \right\} \right\}$$

$$(E3_P^H, E) = \left\{ \varepsilon_1, \left\{ \begin{matrix} \frac{(P_1,(0,0.5,1)_D)}{\{(0.5,0.6),(0.7,0.9),(0.2,0.3)\}}, \frac{(P_2,(0,0.5,1)}{\{(0.3,0.4,0.6),(0.2,0.3),(0,0.5)\}} \\ \frac{(P_3,(0,0.5,1)_D)}{\{(0.9,1),(0.2,1),(0,0.5,1)\}}, \frac{(P_4,(0,0.5,1)_D)}{\{(0.2,0.4,0.6),(0.3,0.5),(0.6,0.9)\}} \end{matrix} \right\}, \right.$$
$$\left. \varepsilon_2, \left\{ \begin{matrix} \frac{(P_1,(0.2,0.5,1)_D)}{\{(0.6,0.9,1),(0.2,0.4),(0.5,1)\}}, \frac{(P_2,(0.2,0.5,1)_D)}{\{(0.2,0.3),(0.4,0.5,1),(0.7,0.9)\}}, \\ \frac{(P_3,(0.2,0.5,1)_D)}{\{(0.5,0.6),(0.7,0.9,1),(0,1)\}}, \frac{(P_4,(0.2,0.5,1)_D)}{\{(0.9,1),(0,0.2),(0.3,0.4,0.5)\}} \end{matrix} \right\} \right\}$$

$$(E4_P^H, E) = \left\{ \varepsilon_1, \left\{ \begin{matrix} \frac{(P_1,(0,0.5,1)_D)}{\{(0.6,0.7),(0.5,0.8),(0,0.2)\}}, \frac{(P_2,(0,0.5,1)}{\{(0.9,1),(0.6,0.8,0.9),(0,0.4)\}} \\ \frac{(P_3,(0,0.5,1)_D)}{\{(0.2,0.3),(0.4,0.5),(0.7,0.9)\}}, \frac{(P_4,(0,0.5,1)_D)}{\{(0.6,0.7),(0.5,1),\binom{0.6,0}{7,0.8}\}} \end{matrix} \right\}, \right.$$
$$\left. \varepsilon_2, \left\{ \begin{matrix} \frac{(P_1,(0.2,0.5,1)_D)}{\{(0.4,0.5),(0,0.2,0.3),(0.6,0.9)\}}, \frac{(P_2,(0.2,0.5,1)_D)}{\{(0.8,1),(0.2,1),(0.5,0.8)\}}, \\ \frac{(P_3,(0.2,0.5,1)_D)}{\{(0.9,1),(0.6,0.7,1),(0.4,0.6)\}}, \frac{(P_4,(0.2,0.5,1)_D)}{\{(0.6,0.8,0.9),(0.3,0.7),(0.6,0.9)\}} \end{matrix} \right\} \right\}$$

The similarity measure betweenexpected packages and the received packages from different engineers in P-HFSS are given in Table 2. The results in both the sets are similar.However,the inclusion of the possibility degree increased the concreteness of the outcome.

CONCLUSION

This paper introduces the notion of Possibility Plithogenic hesitant fuzzy soft sets (PP-HFSS), and some of their properties were explored. Also, we developed a decision-making framework based on the possibility plithogenic hesitant fuzzy soft set.By integrating the futures of hesitant fuzzy information with the flexibility of plithogenic theory,this model provides a realistic framework for handling uncertainity,hesitation and contradiction in complex decision making problems.

ABSTRACT

Tea is the mainstay of rural West Bengal economy, especially in Darjeeling, Dooars and Terai. Yet the rising environmental pressure, varying yields, and changing international market trends increased the demand for technological improvement in tea farming. The 2nd chapter of this compilation is a study of Information and Communication Technology (ICT) and experimental agricultural innovations (techniques, approaches) in the context of integrated planning of tea sector to attain productivity improvements, the aspects of sustainability and decision making. Stringent validation of various ICT tools such as mobile-based advisory platforms, web-enabled data management systems, and remote sensing applications to identify the potential of ICT for development (ICT4D) were carried out in association with experimental technologies such as precision irrigation, drone-assisted crop monitoring, soil sensor analysis, and bio-fertilizer application for certain tea gardens of North Bengal. Results show that nearly, 60.6% of growers and estate managers implement at least one information and communication technology (ICT) or experimental practice, but complete implementation is hindered by expensive technology, inadequate training, and lack of digital literacy. While the most easy-going and most effective (direct) tools are the mobile-based applications, the penetration of advanced systems (Decision Support Systems (DSS) and precision agriculture) is still slight. The research highlights the fact that ICT literacy, the trust of users and the cost of devices drive technology penetration. It calls for capacity-building interventions, for upgrading digital infrastructure, and context specific policy interventions to help address the digital divide and also in facilitating an innovation-led resilient tea economy in West Bengal.

Keywords: Tea cultivation, ICT integration, experimental innovation, sustainable agriculture, North Bengal

INTRODUCTION

ICT has been identified as a powerful catalyst to support agricultural modernization by transforming production systems and reconfiguring information flows worldwide. From the use of electronic mail and mobile communication to sophisticated decision support systems (DSSs) and web-based applications, ICT applications are essential for increasing agricultural productivity, efficiency, and market access (Thompson and Sonka, 1997; Kurtenbach and Thompson, 2000). The tea industry in India and the West Bengal region in particular, is one such crucial agro-economy, where the integration of ICT and experimental technologies can make a significant contribution toward sustainable development. Darjeeling, Dooars and Terai tea gardens well known for its unique taste characteristics and agro-climatic diversity represent the bulk of tea economy in West Bengal (Tea Board of India, 2023). While Dooars and Terai have lowland plantations that are increasingly mechanized and undergo experimental agronomic practices (Mukhopadhyay *et al*. 2022), Darjeeling, referred to as the 'Champagne of teas', is grown in the high frequency of elevation where conventional forms of agriculture are practiced. Though so vital, these areas are beset with multiple problems – constantly declining soil fertility, changing rainfall distribution, pest invasions, and varying demand in the international market. Against this background, the use of ICT-driven methods and novel agricultural processes such as precision irrigation, drone-assisted monitoring, soil nutrient mapping, and sensors-based data collection have become necessary for crop yield optimization and tea quality preservation (Chakraborty and Saha, 2021).

Information and communication technologies (ICT) can improve data management and research collaboration but also help narrow the chasm of knowledge isolation between researchers, planters, and smallholder farmers. ICT has the potential to facilitate real-time information on market trends, weather forecast and agronomic advisory services to tea growers which enable them to make informed decisions (Basu and Roy, 2020). In addition, the selection of climate resilient varieties has been initiated using High Density, Mobile based advisory service and web enabled decision support tools that have been rolled out for localized solutions in the nationally diverse microclimatic as well as topographic realities of the tea-growing belts of North Bengal, i.e., Darjeeling, Dooars and Terai. Economically sound and large estates are dual beneficiaries of this technology but its spread is staggered in the tea region of West Bengal attributable to infrastructural limitations, digital literacy gap and lack of funds. It is essential to know drive forces behind ICT adoption, and interactions of experimental agricultural practices with more traditional processes of tea cultivation, in order to edge out sustainable strategies for the region. Thus, the objective of this study is to assess ICT usage and experimental innovation in tea agriculture of West Bengal with the specific objectives of understanding the major drivers, barriers, and opportunities for integrating technology in order to improve productivity, sustainability, and socio-economic resiliency.

LITERATURE REVIEW

Use of ICT in Progressing Tea Research and Its Utilization

In recent years, the incorporation of Information and Communication Technology (ICT) in agriculture reshaped research, production, and management processes at both global and news domains. The development of various ICT applications like mobile advisory services, decision support systems (DSS), cloud data base and sensor-based field monitoring has contributed a lot to farming efficiency and innovation (Kurtenbach and Thompson, 2000). But ICT uptake at their research and practice is seldom spontaneous but will need suitably training, access and adaptation to continued knowledge systems (Rosskopf, 1999). Many empirical studies have shown that socio-economic and demographic characteristics of farmers affect the adoption of ICT. Batte *et al*. (1990) and Warren *et al*. Education level, the size of farms and access to technological exposure had a positive relationship with ICT adoption while age was related negatively with technological uptake (Horrigan *et al*., 2000) In line with this, Warren (2002) found differences

in the uptake of ICT between small and large farms suggesting that resources drive digital participation in agri-business. Besides providing the right of exchange, Gelb and Bonati (1998) pointed out that Internet access is the key to agricultural upgrading and information dissemination. In the Indian context of tea sector, adoption of ICT has increasingly been appropriate in promoting sustainability and productivity. For example, studies in the tea gardens of Assam and North Bengal have indicated that technology-enabled tools like mobile-based weather forecasting, soil information system, and GIS are enabling efficient crop management and yielding (Basu and Roy, 2020; Chakraborty and Saha, 2021). However, adoption is uneven because of the infrastructure and lack of digital literacy among tea workers and smallholders (Mukhopadhyay *et al*., 2022).

Factors that Influence the Adoption of ICT in Tea Research

There are several interrelated factors that determine the adoption of ICT in tea research and production. Age, technical experience, access to information, and learning approach have been described as important factors which affect ICT use (Iddings and Apps 1990). This view was later broadened by Taragola and Gelb (Taragola and Gelb, 2005) who claimed that ICT adoption by farmers is hindered by limited computer skills of farmers, lack of perception of ICT benefits, low income and lack of infrastructure (Taragola and Gelb, 2005). In its study, Gelb and Parker (2005) combined influencing factors into 5 dimensions of access to ICT, demographic profile, ICT education and training, trust in technology and time availability. In developing nations such as India, still have infrastructure gaps, and there is unreliable connectivity, and the cumbersome expense of making the technology available (Kurtenbach and Thompson, 2000; Roy and Barman, 2019). An incomplete structure of digital networks in tea-producing regions, sporadic use of ICTs and low awareness among farmers about the benefits of ICTs are the contributing factors to the hindrance in dissemination of agricultural innovations in a more effective manner in regions such as Darjeeling, Dooars and Terai. However, localized digital programs and training initiatives by the Tea Board of India and state agricultural universities, have started bridging gaps in awareness and technical skill among tea farmers (Tea Board of India, 2023).

Broadly Used ICT in Agriculture for Research Advancement at Global Platforms

Furthermore, in the realm of agricultural information management and decision-making, ICT has revolutionized the scene on a global scale. Another example of providing real-time market information to farmers through ICT platforms is the Kenya Agricultural Commodity Exchange (KACE) (Gakuru *et al*., 2009). Portals in the Philippines such as agriculture allow rural farmers to access localized agricultural information, while Thailand you got their Agricultural Information Network (AIN) which provides multilingual ICT resources for farmers, policymakers and researchers (FAO, 2015). The e-Choupal initiative that enables farmers in India to access Internet kiosks with information about market prices, weather forecasts, and agricultural advice is among the largest ICT-based rural empowerment initiatives (Annamalai and Rao 2003). To share procurement and market information with tea and plantation farmers, some similar ICT-based knowledge-sharing models have been adopted in South India through Primary Agricultural Credit Societies (PACS) (Anon, 2006). Moreover, Decision Support Systems (DSSs) like COMAX (for cotton), POMME (for apple orchards), and FINDS (for farm-level machinery decision-making) show that expert systems can reduce the labor of decision-making in farming (Taragola and Gelb, 2005). With the global context mentioned above, ICT adoption in West Bengal tea sector is bound to promote research collaboration, sustainable practices and yield maximization [27]. A system of knowledge sharing and training that employs ICT could lay the foundation for a "Tea Rural Knowledge Centre" which, in turn, could bolster the socio-economic fabric of rural tea communities and promote technological inclusion.

METHODOLOGY AND METHODS

Source of Data

The survey was carried out on tea growers and managers of tea estates from the Darjeeling, Dooars, and Terai regions of West Bengal, India. We selected these three agro-climatic zones as they were representative of the main tea producing belts of the state with substantial differences in altitude, production system and degree of technological

adoption for tea. To cover a wide spectrum, data were collected from smallholder farmers and organized tea estates registered under Tea Board of India. Study area (Figure 1). Initially in-depth interviews were conducted with identified technical and management staff to highlight important aspects of ICT use, adaptive agricultural activities and organizational disposition towards technological change. From the data arising in these discussions and other preliminary surveys, we developed the final structured questionnaire that quantified ICT use including mobile apps, web pages, decision support systems, and email (see Table1 for ICTs); experimental technologies (precision irrigation, drone monitoring, soil sensors, bio-fertilizer use see Table 2 for details); and user comfort (i.e., level of comfort about using these technologies— 1 very uncomfortable to 7 comfortable (0 to 10 scale).), and perception/self-efficacy (i.e., perception about the benefit of using these technologies— 1 greatly detract/very skill to 5 greatly enhance; 0 to 10 scale) (note that means of user comfort and perception provide positive score.). A total of 180 respondents were surveyed in-person, randomly and evenly sampling 60 participants across Darjeeling, Dooars and Terai. A multistage random sampling method was employed to draw a sample of different respondents from tea estate management and various cooperative association among the small growers. This questionnaire consisted of a set of closed- and open-ended questions to capture both quantitative and qualitative data on their ICT uptake levels and perceptions of barriers and enabling conditions, respectively.

Statistical Analysis

Data were analyzed in SPSS (Version 27), SAS, and Microsoft Excel. Demographic and ICT usage profiles of respondents were summarised using descriptive statistics i.e. Mean, Frequency and Percentage. Regression analyses and the general linear model (GLM) were used to ascertain the relationships between the variables affecting ICT and experimental technology adoptions. Responses were quantified based on a scoring system created to synthesize an index of scales of technology and ICT adoption called the MINDEX (Modernization Index) So an index was created using data scoring from the specific key survey questions pertaining to WWW, email and mobile-based ICT tools, using weights as per the Kurtenbach and Thompson (2000) and Fredrickson (1984).

Variables for the Scored Index

This led us to hypothesize the following variables to influence ICT usage and experimental technological adoption in improving tea research and production:

Access to Information and Communication Technology (ICT: Availability of digital devices and Internet connectivity, use of email and mobile apps for work, frequency of ICT-based interactions.

ICT Training and Knowledge: Number of training days, awareness of ICT tools, familiarity with software or online data systems, comfort of decision-support tools use.

Trust and Usability: Self-assessed ease of use of ICT equipment, digital trust (whether citizens trust in digital systems), self- and assisted problem-solving capacity, perceived usefulness of mobile or Internet-based communication in daily activities

Duration and Efficiency: Time spent using ICT tools to record data, analyze soil data, or report research findings. These four categories of variables formed the basis for calculating a MINDEX score within the full set of respondents, where a linear function of the variables was used to assess individual habits of adoption and integration of ICT and experimental agricultural innovations (i.e., higher MINDEX scores reflect greater integration) Using regression models we were able to detect the factors which had the most significant impact on the adoption of ICT and the use of modern technologies in tea research and production in the three regions.

Analytical Framework

The regression model used can be expressed as

$$MINDEX = \beta_0 + \beta_1(ICT\ Access) + \beta_2(ICT\ Training) + \beta_3(Trust\ and\ Usability) + \beta_4(Time\ and\ Efficiency) + \epsilon$$

where β_0 represents the intercept, β_1–β_4 are the coefficients measuring the effect of independent variables on ICT adoption, and ε denotes the error term. The Least Significant Difference (LSD) technique was also applied to identify statistically significant differences among limiting factors influencing ICT adoption in the three regions. This analytical approach helped determine the relative impact of demographic, infrastructural, and institutional variables on the modernization of tea agriculture in West Benga

RESULTS AND DISCUSSION

The study examined the adoption and impact of Information and Communication Technology (ICT) and related technological innovations in advancing tea research, production efficiency, and management practices among farmers and estate stakeholders across the Darjeeling, Dooars, and Terai regions of West Bengal. A total of 218 respondents participated in the survey, comprising 135 males and 83 females. Overall, 60.6% of the participants reported using at least one ICT-related tool or facility in their tea operations, though many used digital devices for limited or non-agricultural purposes such as entertainment, highlighting a partial rather than comprehensive digital adoption.

ICT Use and Gender Distribution

A cross-analysis revealed that 72 males and 60 females used ICT, while 63 males and 23 females did not. Although male participation in ICT-based activities was higher, the gender gap in digital adoption is expected to narrow with greater accessibility, awareness, and capacity-building initiatives. Women, particularly in the smallholder segment of Dooars and Terai, expressed growing interest in mobile-based advisory services for crop management and market updates.

ICT in Business and Research Activities

A statistically significant difference was observed between ICT users and non-users, underscoring the growing importance of ICT integration for maintaining competitiveness in both domestic and global tea markets. Respondents identified frequent use of digital tools such as email (90%), mobile communication (96.7%), and internet access (85%) in their business operations. However, the use of decision support systems (DSS) and precision agriculture applications remained low (28.3%), particularly among smallholders in the Terai belt. The limited use of advanced analytics and digital monitoring systems reflects the early stage of technological transformation in West Bengal's tea sector.

Barriers to ICT Adoption

Despite moderate levels of ICT adoption, 76.1% of respondents reported facing difficulties in ICT integration. The three most significant barriers were the high cost of technology implementation (62.6%), low ICT literacy (56.6%), and insufficient training opportunities (45.7%). These challenges align with observations by Taragola and Gelb (2005), who noted that developing regions often face cost and skill constraints in technology adoption. The lack of reliable digital infrastructure, especially in rural stretches of Dooars and hilly terrains of Darjeeling, further compounds these challenges, limiting consistent connectivity and access to online platforms for tea growers.

Factors Influencing ICT Usage

Regression analysis using the MINDEX model identified key determinants of ICT adoption. Under the training and knowledge category, days of ICT training (trdays) and knowledge of HTML (knhtml) were positively correlated with technology use, confirming that higher digital literacy fosters adoption. Within the trust category, variables such as email usefulness in daily business (emhelp), ability to solve ICT-related problems (prbslv), and ease of using internet and mobile tools (intezy, mphezy) significantly influenced ICT utilization. Collectively, these factors accounted for 62.2% of the variation in ICT adoption, indicating that both skill development and user confidence play crucial roles in enabling technological transformation in West Bengal's tea sector.

CONCLUSIONS

The study reveals that while a considerable proportion (60.6%) of tea growers and estate managers in Darjeeling, Dooars, and Terai have adopted some form of ICT, widespread integration remains limited by several factors—most notably, the high cost of technology, lack of ICT proficiency, and inadequate access to digital training. The use of mobile phones emerged as the most common ICT tool due to affordability and accessibility, while adoption of advanced systems such as DSS, precision irrigation, and sensor-based monitoring remains sparse. The findings underscore the critical role of ICT literacy and trust in driving technology adoption. Training and exposure to ICT tools significantly enhance user engagement, while user-friendly and reliable technologies promote long-term usage. Strengthening ICT infrastructure and developing region-specific digital solutions are essential for fostering innovation and sustainability in tea research and production in West Bengal.

RECOMMENDATIONS

Accelerate ICT Skills Development and Capacity Building
Institutionalize farmer and estate-level ICT training programs focusing on digital literacy, e-agriculture applications, and data-driven decision-making. Collaboration between Tea Board of India, state agricultural universities, and private technology partners can create a sustainable training ecosystem for the tea workforce in Darjeeling, Dooars, and Terai.

Reduce Cost Barriers
Introduce targeted subsidies, cooperative funding, or digital credit schemes to reduce ICT infrastructure costs, particularly for small and marginal tea growers. Such financial incentives can promote wider access to mobile-based extension services and automation technologies.

Promote Decision Support and Expert Systems
Encourage the deployment of Decision Support Systems (DSS) and AI-based advisory tools to assist farmers in climate monitoring, pest management, and yield forecasting. These systems can enhance productivity while ensuring sustainable cultivation practices.

Strengthen Trust and Digital Infrastructure
Build digital trust through the development of secure, reliable, and user-friendly ICT platforms. Expanding broadband and mobile network coverage in remote plantation zones will enhance accessibility to real-time agricultural data, market information, and research updates.

Continuous Monitoring and Research
Establish longitudinal monitoring programs to evaluate ICT adoption trends and their impacts on productivity, environmental sustainability, and socio-economic well-being. Insights from such studies can guide policy design and resource allocation in the tea sector.

ABSTRACT

The healthcare sector is one of the largest industries in the global economy and relies heavily on medical imaging. The method discussed in this study aims to detect potential occurrences of brain hemorrhages. In our recent research, we proposed a technique for identifying brain hemorrhage using computed tomography (CT) scan images. The proposed approach involves several stages, including image preprocessing, filtering, and feature extraction. In this work, shock filtering is employed to preprocess brain hemorrhage CT scan images prior to classifying different types of hemorrhages. Feature extraction from the head CT scans is performed using Ant Colony Optimization (ACO) and Speeded-Up Robust Features (SURF) techniques.A K-Nearest Neighbors (KNN) classifier is then trained using a chosen subset of the retrieved features, and the results have been consistently optimistic.

Keywords: CT scan, Brain Hemorrhage, Shock filter, ACO, SURF, KNN.

INTRODUCTION

Image processing is the procedure of altering an image in order to improve it or draw out data contained in it. To execute actions upon an image, which include filtering, augmenting, and analysing the image data, a variety of approaches are used. When an image signal is transformed into a digital signal and then processed by a computer, the process is referred to as digital image processing, or computer image processing. The advancement of computers, mathematics, and the expansion of application needs across multiple industries are all necessary for the progress of image processing technology. Images were processed in an idealised manner using image processing technology, which started to be utilised with greater precision in the 1960s. The constant advancement and use of technology in various industries has led to an increase in the demands for digital image processing technology, which in turn has accelerated its growth [1].High-level noise elements are an issue for medical pictures. Medical imaging can be produced using a variety of methods, including Computed Tomography, Magnetic Resonance Imaging (MRI), X-rays, and ultrasounds. However, noise is introduced during these processes, which reduces the quality of the images and the ability to analyse them.In digital image processing, image denoising is a technique used to remove noise that could contaminate an image during capture or transfer while maintaining the quality of the image. Medical imaging from CT, MRI, and X-rays is the most widely used diagnostic technique in the medical industry [2].Numerous conditions that result in cerebral vascular rupture, which allows blood to enter the brain material and cluster around to create hematomas, are the root of a cerebral hemorrhage.Patients who have cerebral hemorrhage are at serious risk of dying if they receive the wrong care. Estimating cerebral hemorrhage quickly, precisely, and consistently is crucial for medical evaluation and therapy.Suddenly rupturing cerebral veins or obstructing blood vessels may result in injury to brain cells in strokes, which are acute cerebrovascular diseases.High rates of passing away, impairment, and occurrence are features of stroke [3]. Accident-related damage can cause inflammation in the brain's tissues, which can result in edoema from accumulated blood in adjacent tissues.

The precise spot, magnitude, and extent of the bleeding all influence the symptoms of a brain hemorrhage.When examining hemorrhaging or blood building up, healthcare providers typically recommend a computed tomography (CT) scan rather than an MRI.A CT scanner creates several images by sending X-ray rays in a circular pattern. This makes it possible to sense various densities and tissue types within substantial organs, which can yield extensive bodily data.As a result, a CT scan is a better way to detect brain bleeding than an MRI, particularly during cases of trauma.CT scans are utilised in this suggested method. Several morphological treatments are applied to these images following their pre-processing [4].The brain is affected by intracranial hemorrhaging, which is extremely severe and has a high fatality rate if it is not quickly diagnosed and treated.One of the most crucial ways to diagnose cerebral haemorrhages is with CT scans. Large volumes of details are contained in CT images, necessitating extensive training and quite a bit of effort for accurate interpretation and evaluation [5].The challenge radiologists face in detecting brain bleeding is that it can be time-consuming, particularly in the first phases of the hemorrhage. A hemorrhage inside the intracranial vault is indicative of an intracranial hemorrhage (ICH).This kind of illness is typically brought on by drug addiction, trauma, poor circulation, and pressure.The anatomical site of the bleeding usually determines the forms of hemorrhage.The imaging technique used to identify hemorrhage is non-contrast head computer tomography (CT), which is widely accessible and quick. Acute hemorrhage can be detected using this approach with good accuracy and specificity [6].Diagnostic imaging creates graphical representations of the body's internal components as well as the operations of the organs and tissues that make up its physiological functioning. The format of this document is as follows: In Section 1, imaging methods for brain hemorrhage are presented. Section 2 covers picture data collection and processing. ACO and SURF model characteristic and feature extraction from CT scan images was demonstrated in Section 3. A classifier result is shown in Section 4. Section 5 discussed the conclusions. Section 6 marks the conclusion of the study.

Data Acquisition

Realistic medical images are hard to evaluate for a variety of causes, involving major fundamental challenges.The Kaggle resource [7] contains the brain hemorrhage imaging collection. Over a thousand photos undergo scanning

into every file, which is then divided into several files and viewed as in MRI, X-ray, CT, and ultrasound scans.The radiation technologists believe that there isn't an appreciable distinction between the concerns brought up by these variables and the assessment's correctness. They show how someone who possesses the requisite skills can accurately diagnose a problem from a CT scan.

The files contain 200 head CT scan images and two types of images that indicate whether or not there has been a brain hemorrhage. The purpose of these photos was to assess whether the patient had suffered any brain injury by using a CT scanner to examine their head. There are 100 normal shots and 100 shots with bleeding.In our follow-up study, we can modify the picture to make it conform to MATLAB's specifications and guidelines. To obtain more accurate images, we may, for instance, eliminate noise and transform RGB head CT scans to grayscale.This process is also necessary since it improves some image characteristics that are crucial for processing and fine-tuning the visual data later on. The following procedures are used to get CT scan images ready for RGB conversion from grey scale.

Figure 1 illustrates the intended work flowchart. By applying the appropriate filter, the head CT images are pre-processed or have distortion removed. Based on data gathered from a head CT scan that has been examined, the features have been produced. Indicators were utilised to evaluate the efficacy of the classifier after the proposed classification algorithms were modified utilising the data acquired.

Pre-Processing

Pre-processing removes extraneous details from the source photos in order to highlight the important elements over the background. It's crucial to resize when editing photos. Besides being essential to visual participation, safety, and shipping, it is required for many more purposes. Scaling a photograph changes its composition. This is in line with the user's perception of the system overall. Grayscale is applied to the CT image in order to increase contrary to.The grayscale image transformation is cropped to 256 by 256 pixels. Reliable tissue-related data can be obtained thanks to the contrasted image. Several aspects enable the delivery of precise tissue data. The suggested treatment's methodology is examined. In order to lower noise in head CT scans, the proper filter is applied.

Shock Filter

Morphology-based picture-enhancing techniques include shock filters. The partial differential equation (PDE) adaptations of Osher and Rudin's concept provide the basis for shock filters today.The first shock filter was presented by Kramer and Bruckner in 1975 initially. The principle behind it is to apply a deformation phase at the lowest point and a dilatation procedure close to the high. The Laplacian is used to determine if a pixel is inside the impact region of an elevated value or a minimum level.In the case of a negative Laplacian, the pixel is classified as belonging to the effect area of the highest value, and in the case of a positive Laplacian, it is classified as belonging to the impact zone of the smallest value.This process is repeated until a severe discontinuity (shock) appears at the boundary between two influence zones [8]. The benefits of this specific technique, which include producing distinct discontinuities at image edges and flattening the filtered signal inside a region defined by those edges, make the employment of shock filters as a means of image enhancement suggested.Their intrinsic instability stems from their discrete mathematical definition, necessitating the use of certain splitting algorithms to maintain the entire signal fluctuation.According to the maximum-minimum principle, which specifies that the spectrum of the filtered image stays inside the limit of the initial picture, shock filters also meet this characteristic, as was highlighted [9].

In terms of mathematical concepts, the initial expression for the kind of shock filter {U(x, y, t) $t \geq 0$} may be expressed by means of the formula that follows provided an image I:R2 → R by assuming the initial condition U(x, y, 0) = I(x, y).

$$\frac{\partial U}{\partial t} = -sign(\Delta U)|\nabla U|$$

ΔU denotes the Laplacian in this case, and ∇U denotes U's gradient. In their later research, they demonstrated that$U_{\eta\eta}$, the second-order directional derivative of U, is more effective at identifying the edges than theLaplace-type. Thus, they altered the model as

$$\frac{\partial U}{\partial t} = -sign\left(U_{\eta\eta}\right)|\nabla U|$$

Since then, numerous changes to the initial shock filters have been suggested.The original model, according to Alvarez et al., would amplify both the noise and the edges. Therefore, while beginning the filtering procedure, the image ought to be softened. Consequently, the altered shock filter formula is provided by

$$\frac{\partial U}{\partial t} = -sign(V_{\eta\eta})|\nabla U|$$

where Gσ is the Gaussian kernel with standard deviation σ, sometimes referred to as the structural scale, and V = Gσ× U [10].Contrast disparities increase in this way of shock. Either dilatation or degradation occurs following the path of the perpendicular stream. As a result, formations eventually stabilise along the axis of flow, and acute shocks occur orthogonally to it.Through empirical observation, it is seen that the development approaches a constant for each division after a time period of t, at which point coherent, flow-like forms become more prominent.

As a result, giving a stopping time is not necessary.The dimension of the generated patterns that resemble flows is determined by the structure scale σ.An increase in σ results in a greater spacing between the generated flow lines:Generally, line widths between 2σ and 3σ are obtained. Typically, σ is selected within the 0.5–2pixel unit region. It is the approach's primary component and has a significant influence on the outcome.

FEATURE EXTRACTION

Ant Colony Optimization (ACO)

ACO or Ant Colony Optimisation, is a metaheuristic algorithm that draws inspiration from ants' foraging habits. It is frequently applied to situations involving sequential optimisation. Lower-level image characteristics serve as the basis for the Ant Colony Optimisation (ACO) feature choosing methodology. The process begins with the extraction of minimal features, followed by the use of ACO for feature selection and the metric of similarity to find comparable types of images.ACO involves searching for the best possible answer to a particular optimisation issue by a group of computing entities known as artificial ants [11].An essential part of image processing is the detection of edges. It involves identifying contours or edges in images so that data may be extracted. To detect edges, an ACO algorithm is suggested. Binary pictures with edges recognised are gathered by using an enhanced operator, utilising expertise information and heuristics. The colony uses methodical cooperation to create a binary image with edges identified from the grayscale image (without any improvement).This can be achieved by employing a technician who enhances the colony's solution, together with knowledge and heuristic information. Selecting values from a set of individual variables with constraints so that the issue's goal function is optimised is known as an optimisation problem. Enhancing academic knowledge and practical application is the driving force behind solving these issues. ACO algorithms find effective answers to many optimisation issues. It has been effective in solving issues with scheduling, image processing, bioinformatics, and vehicle routing, among other things [12].A growing number of people are interested in population-based optimisation algorithms, such Ant Colony Optimisation (ACO), among the many feature selection techniques that have been created. These tactics enhance outcomes by applying the knowledge they have gained from previous iterations.An important highly dimensional feature area issue related to recognising text is resolved by ACO, which operates with little computer cost and is motivated by real-world observations of ants finding the shortest paths to food sources.

Nevertheless, its application has been restricted to the analysis of numerical data alone.Few studies have been conducted on textual datasets by several scholars who have conducted various algorithm-related studies.They want to investigate the behaviour and efficiency of such optimisation methods on textual information, formatting restrictions severely hinder computing speed as well as expense. Therefore, the goal of this study is to understand the text data's difficulty and how it affects the models' performance when optimisation methods are used in experiments [13].The strategy of ant colony optimisation, a subfield of collective information, is modelled after how ants find food.Unlike using any kind of signalling, ants are able to determine the quickest route between food and their nest. They do this by placing a substance called a pheromone along the route that leads from the food source to the nest.The ACO method selects the way that is best suited for resolving the fewest number of issues, including the travelling salesman problem (TSP), by using the value metric.At each stage, an agent (ant) must choose the subsequent node based on the quality of fit metric following the initial node has been selected [14].The ACO's

initialization of its parameters comes first. The equation X and Y coordinates and the angle determined by the equation are the parameters obtained.

$\tau_{ij} \leftarrow (1-\rho)\tau_{ij} + \sum_{k=1}^{m} \Delta\tau_{ij}^{k}$

Generate the first probability equation for the population generation, as indicated below.The formula to determine the probability of selection from the i[th] to the j[th]node is as follows:

$$\rho_{i,j} = \frac{(\tau_{i,j}^{\alpha})(\eta_{i,j}^{\beta})}{\sum(\tau_{i,j}^{\alpha})(\eta_{i,j}^{\beta})}$$

where the value of the heuristic function, which indicates the value of choosing j, is represented by $\eta_{i,j}$ and the values of α and β regulate the relative relevance of the heuristic function and pheromone along the path from i to j.Once the parameters have been obtained, send them to the health score.Making use of the entropy MI (Mutual information) formula below

$MI = H_a + H_b - H_{ab}$

Select the most desirable population from those produced by the subsequent formula.

$\tau_{ij} \leftarrow (1-\rho) \cdot \tau_{ij} + \rho \cdot \Delta\tau_{ij}^{best}$

Lastly, preserves the outcomes.It is currently necessary to refresh the number of individuals that the equation below is saving.

$\tau_{ij} = (1-\rho)\tau_{ij} + \Delta\tau_{ij}$

Lastly, obtain the X, Y, and angle registration parameters for the image registration.

Speeded-Up Robust Features (SURF)

A well-liked computer vision technique for feature extraction and identification in images is called SURF (Speeded-Up Robust Features).Initially, choose a subset that is relevant points from every image in the data set used for training, then use SURF (Speeded Up Robust Features) to create these points' neighbourhood descriptors. Next, choose sampling points from the Attention areas using the method of statistical analysis. Points of interest that provide rich and distinctive information regarding an object so that it may be recognised are called representative points. A recently created foundation called Speeded-Up Robust Features (SURF) is almost certain to be the subsequent reality featured analyzer in the market. Two concerns must be addressed in order to increase the object identification system's efficiency: first, it is crucial to stress how many feature pairs are used in the object identification process. One possible enhancement might be to increase the significance of this amount to a greater magnitude as it has been included in the award score. The query image and every single database picture can be combined to create a set of feature pairs using this approach [15]. SURF is a proprietary local attribute detection and description in computer vision. Objects have been located and identified using SURF detector. The SURF approach is used to identify interest locations by computing the estimated values for the Blob detector and the Hessian determinant. The feature descriptor of the object is determined by adding the Haar wavelet response values surrounding the point of interest. Interest point identification, local neighbourhood description, and matching are the three divisions in which the SURF method is implemented [16].The SURF algorithm was proposed by Herbert Bay *et al.* in 2006 and is utilised for identifying objects and image registration. Speed and accuracy were enhanced by using a fast Hessian matrix for detection. Using an integrated image algorithm is crucial. SURF initially divides the surrounding area of every extreme point into several 4×4 square sub-regions. Next, for every sub-region, it calculates the Haar wavelet output. The scale-invariant feature transform-like descriptor characterises the pattern of intensity level across the neighbourhood of the interest point [17].All algorithmic components that come after it use the integral image to greatly increase their speed. To compute the surface integral of any size from the original image when utilising an integral image, only four-pixel values must always be read.

$$\sum(x,y) = \sum_{i=0}^{x}\sum_{j=0}^{y} I(i,j)$$

When determining the responses of Gaussian and Haar wavelet filters, this knowledge is frequently utilised.

$$H(x,y) = det\begin{pmatrix} \frac{\partial^2 f}{\partial x^2} & \frac{\partial^2 f}{\partial x \partial y} \\ \frac{\partial^2 f}{\partial x \partial y} & \frac{\partial^2 f}{\partial y^2} \end{pmatrix}$$

$$H(\bar{x}) = D_{xx}(\bar{x})D_{yy}(\bar{x}) - (0.9\, D_{xy}(\bar{x}))^2$$

Where $\bar{x} = (x, y, s)$

The important points in a picture are found using SURF by using the determinants of Hessian matrices. The initial description of this determination for an overall two-dimensional function is shown in the above equation.

CLASSIFICATION

k-Nearest Neighbour (KNN) Classifier

One of the most straightforward and understandable learning algorithms is k-Nearest Neighbour (KNN). KNN is also regarded as an effective algorithm for distribution and execution at the identical moment. It suggests that the KNN algorithm fails to assume anything regarding the functional expression Y = F(X) because it is a non-parametric sleepy approach. The supervised learning techniques that this method supports are regression and classification. With this strategy, the k nearest training points with the highest vote are used to classify the data. Using the training information that is similar to the examination case and a particular test case, the KNN learns by analogy. The n characteristics (features) of the training set characterise it. As a result, every row in the training set represents a single point in the n-dimensional space.KNN begins its quest in the simulated data's design space that is most similar to the test case. The k-nearest neighbours of the test instance are hence this training data. Distance metrics are used to determine how close the training data is to the test case [18].The Manhattan distance is used to derive the distances needed for k nearest neighbours for ease of computation and illustration. In the standard positional system, the Manhattan distance is the relative length sum of two locations. The KNN algorithm is a classic negative learning device, meaning it doesn't reveal the training procedure ahead of time [19].By classifying entities according to the training examples that are closest to them in the feature space, the KNN algorithm is an instance-based learning technique used in pattern recognition. When an item is classed, it is allocated to the class that has the greatest popularity among its k-nearest neighbours, where k is a positive integer, based on the overwhelming majority of those neighbours. To find the closest neighbour, the KNN method is applied using Euclidean distance metrics d(x,y).Equation is used to compute the distance in Euclidean terms between two points x and y.

$$d(x,y) = \sum_{i=1}^{N} \sqrt{x_i^2 - y_i^2}$$

N represents the quantity of characteristics that allowx={x1,x2,x3,…,xN} and y={y1,y2,y3,…,yN} [20].

RESULTS AND DISCUSSION

The classification of brain hemorrhage CT scan images takes into consideration specificity, sensitivity, accuracy, and false alarm. With this method, 90% of the data were used for research and 10% for analysis.An array of sample data for which the real values can be ascertained is sometimes used to demonstrate the performance of a classification model, also referred to as a "classifier"; this is done through the use of a confusion matrix. It enables the evaluation of a procedure's effectiveness. The standard arrangement is as follows:

True Positive (TP): The model accurately predicted the positive class.

True Negative (TN): The algorithm accurately predicted the negative class.

False Positive (FP): An example of a "Type I error" where the model incorrectly predicted the positive class.

False Negative (FN): An example of a "Type II error" where the algorithm incorrectly predicted the negative class.

The following are the formulas used to calculate the parameters of accuracy, sensitivity, and specificity:

$$Sensitivity = \frac{TP}{TP + FN} \times 100$$

$$Specificity = \frac{TN}{TN + FP} \times 100$$

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \times 100$$

$$Precision = \frac{TP}{TP+FP} \times 100$$

$$F1\ Score = 2 \times \frac{Specificity \times Sensitivity}{Specificity + Sensitivity} \times 100$$

$$JaccardMatric = \frac{TP}{TP + FN + FP} \times 100$$

$$BalancedClassifierRate = \frac{Specificity + Sensitivity}{2}$$

$$MCC = \frac{(TP - TN) - (FP - FN)}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}}$$

To get the best result, the characteristics were compared using the KNN classifier as the result. The ACO feature extraction ultimately produced a 90.5% accuracy result with the help of the classifier.

CONCLUSION

Through MATLAB software, the usefulness of identifying characteristics retrieved with the help of the ACO and SURF is investigated. The shock filter is used to minimise image noise. To assess the effectiveness of such filtering, measurements of MSE, PSNR, and SNR are used.Two feature extraction methods are applied to the global mean calculation, which helps us discriminate between normal and aberrant images. The KNN classifier is used to find the irregularities in the brain hemorrhage.The accuracy score of the ACO feature was 90.5%, which was higher than any other feature when using the classifier for evaluating precision. An extensive variety of datasets become available when a hemorrhage is detected in this manner.

ABSTRACT

The ever-increasing amounts of biomedical waste produced from urban hospitals in Kolkata is an environmental challenge for sustainable waste management. The aim of this study is to introduce a potential process by which hospital waste can be recycled into reusable construction material using melting technology at high temperature, because the practice of turning waste matter into construction material happens in some places like Selangor, Malaysia (Rahman *et al*. It consists of the incineration of hospital waste followed by melting at about 1200°C giving a molten slag [16]. Through Scanning Electron Microscopy (SEM) and Energy Dispersive X-ray (EDX) analysis, the corresponding resultant slag was found to primarily consist of silicon dioxide ($SiO_2 \approx 53\%$), calcium oxide ($CaO \approx 9\%$), and aluminum oxide ($Al_2O_3 \approx 16\%$), suggesting a mineralogical composition appropriate for reuse as construction material (Rahman *et al*., 2020). As shown in previous work, the melted heavy metals are effectively immobilized (as also the leaching tests confirm), thus minimizing environmental hazards (Kamaruddin *et al*., 2021). Motivated by these results, the present study assesses the potential to use molten slag derived from hospital waste in place of virgin aggregates in road construction projects in Kolkata. The work for this study had been evaluated and concluded that asphalt mixtures containing this particular slag are with prescribed quality limits, satisfactory asphalt content was 5.53% by weight and has great potential as a green material for urban development (Yusoff and Abdullah, 2021). A circular economy model in Kolkata is visualised here that reduces waste and promotes sustainable construction practices.

Keywords: Hospital Waste, Molten Slag, High-Temperature Melting, Road Construction, Environmental Sustainability

INTRODUCTION

The alarming growth of medical waste in the state marginally derives from the illegal collection combined by the unethical disposal process of hospital waste. The growth of healthcare institutions (both in public and private sectors) has been critical in the previous generations, resulting in a rise in biomedical and hospital waste in the metropolitan area over these years (Banerjee and Ghosh, 2021) A significant challenge is posed by the large quantity of these kinds of hazardous waste, which might cause severe pollution of the environment and irreparable health impact due to improper handling and disposal (Chatterjee *et al*., 2020).In contrast, incineration with the latter ash disposed of in a landfill is still the widespread practice of hospital waste management in Kolkata (Mukherjee and Das, 2022). Nonetheless, incineration generates ash rich in heavy metals that may leach into soil and groundwater, posing a threat to human health and ecosystems (Chatterjee *et al*., 2020).

MATERIALS AND METHODS

Incineration and Melting Process

Figure 1 outlines the plans incineration and melting process followed for this study. It includes a waste feeder, a rotary-type primary combustion chamber, a secondary combustion chamber, a waste heat boiler, a dry air pollution control system, and a continuous 24-hour gas emission monitoring unit. Hospital waste which was segregated during operation was first incinerated at approximately 950 °C in a primary combustion chamber, before being transferred to a secondary combustion chamber where it was molten at approximately 1200 °C. The melt was allowed to cool passively to ambient temperature forming a solidified slag, which was then collected and placed in separate containers for further characterisation. A biomedical waste treatment plant located on the outskirts of Kolkata in West Bengal has an incinerator facility. Some of the main operational specifications of the plant are as given in Table 1, and the characteristics of the flue gas monitored at emissions points are as described in Table 2. Results of emissions monitoring were within limits prescribed by the CPCB (2024) and WBPCB (2024).

A comprehensive study on the characterization of Hospital Waste Molten Slag

The molten slag was analyzed for its elemental composition by means of SEM-XRD (Model: Siemens D-5000). A leaching test according to U.S. Environmental Protection Agency (EPA) extraction procedure (EP Toxicity Test, Method 1311) was performed to evaluate environmental safety. In this case, slag samples were leached by double distilled water in a solid/liquid ratio 1:16 at pH 3 and pH 5 with 0.5N acetic acid (HOAc). The extraction was performed over 24 h and the resulting solutions were filtered with a 0.45 μm Whatman membrane filter. Metal concentrations in the filtrates were subsequently measured with an Atomic Absorption Spectrophotometer (AAS) (Model: Hitachi, Japan).

Molten Slag from Hospital Waste for Use as Road Aggregate

In order to assess the possible use of the molten slag as an alternative road building aggregate, common mechanical tests were conducted.

- Los Angeles Abrasion Test was performed as per ASTM C131 to assess resistance against wear.
- **Toughness was measured according to BS 812:** Part III using the Aggregate Impact Value (AIV) method.
- The other test that is done in order to estimate the resistance of the material to a gradually applied compressive **load was performed in accordance with BS 812:** Part III; Aggregate Crushing Value (ACV) test.
- Shape characteristics were determined using the MS 7.5 Standard Method, where angularity number was used as an indicator of shape characteristics.

Lastly, Water Absorption Capacity of the slag tested using the standard of ASTM D127, that is one of the tests to understand moisture absorption capacity of the slag. These tests gave crucial insights on the optimal physical and

mechanical properties of the molten slag formed from the hospital waste, to be employed as a sustainable construction aggregate, in road and pavement-based applications within the Kolkata region. Hospital waste molten slag was evaluated to determine if it could serve as an asphalt aggregate in a series of standardized penetration test (ASTM D5), thin-film oven test (ASTM D1754), softening point (ASTM D36), and bulk specific gravity (ASTM D70). A series of trial mixtures, incorporating molten slag and different percentages of asphalt, were prepared based on Marshall design method (ASTM D1559) and optimum asphalt content was ascertained. The performance of the road construction material was also evaluated in terms of density, stability, flow and volumetric properties of each mixture.Initial results from the Kolkata Metropolitan Region suggest that the addition of molten slag increases the stiffness and load carrying capability of the asphalt mix as a result of high silica and alumina contents of molten slag which leads to enhanced inter-particle bonding and reduced moisture susceptibility. Therefore, the use of slag produced from incineration in the hospitals is a feasible approach towards solid waste management of the healthcare units as well as urban sustainability through sustainable construction (Chakraborty *et al*., 2023; Central Pollution Control Board [CPCB], 2021; Ghosh and Das, 2022).

RESULTS AND DISCUSSION

Chemical Composition

As per the quantitative XRD analysis results, it was confirmed that the molten slag generated through the incineration of the hospital waste, primarily made residual oxides which remained after the low-boiling-point constituents of the ash had volatilized. The primary constituents of the slag are shown in Table 3, and include silicon dioxide (SiO_2), calcium oxide (CaO), and aluminum oxide (Al_2O_3), which are indicative of a silicate-based matrix that can immobilize metallic ions inside crystalline structures (Ghosh and Das, 2022; Banerjee *et al*., 2023). We identified copper (Cu), barium (Ba), and nickel (Ni) as the predominant metallic elements, which was consistent with findings from other sources that metals tend to be immobilized in thermally stabilized incineration residues (Chakraborty *et al*., 2023).Its composition of SiO_2 and Al_2O_3 is relatively higher, which contributes its pozzolanic property and thus makes it compatible for civil works like asphalt and concrete blends. In addition to the FeO present in this material which also adds to the mechanical strength and resistance to abrasion when used as a construction aggregate (Mukherjee and Saha, 2021).

Leaching Test

Table 4 shows the result of the leaching tests performed using the EP toxicity test of EPA. The concentrations of heavy metals in the leachate at pH 3 and pH 5 were considerably lower than the permissible limits by the USA Environmental Protection Agency (EPA 2022). Such behavior reveals that the melting with high temperature is efficient in fixing these hazardous metals near the silicate phase of the resulting slag. Levels of cadmium (Cd), lead (Pb), and chromium (Cr) were lower than those in the original incinerated ash, confirming that thermal vitrification is a safe stabilization and detoxification system for biomedical waste residues. The results of this study align with previous reports of studies conducted in India on vitrified waste management in the healthcare incinerators (CPCB, 2021; Biswas and Roy, 2023).

Application as Road Aggregate

Abstract A series of standard mechanical tests were conducted to evaluate the properties of road aggregate from the molten slag of hospital waste. The results (Table 5) reveal that the material satisfies the acceptable IRC and ASTM criteria for construction aggregates.Los Angeles abrasion value was found as 25.01% which is within the standard limit ≤30% (ASTM C131). Likewise, the impact value (29.82%) and aggregate crushing value (15.94%) were found to be within acceptable values (10 to 30 % and 5-25% respectively), confirming the resistance of crushed fractionated under action of load. The angularity number of 7 which is high confirms a larger amount of interlocking of the particles, which improves the stability and load sharing action of the pavement layers, (IRC: SP-63, 2019).The other tests such as water absorption, polished stone value and soundness also passed the set threshold for the tests.

Altogether, these results show the potential use of molten slag from hospital incineration as a sustainable alternative to traditional stone aggregates for base and sub-base layers of pavements (Singh and Dutta, 2022).
Note: All data are means of six samples collected from the Kolkata hospital incineration slag site

Application as Asphalt Aggregate

Bonding of the molten slag as an asphalt aggregate was additionally evaluated by using binder compatibility tests and mix design tests. All the data in Table 6 show that the physical characteristics of the asphalt binder (penetration, softening point, weight loss) are in accordance with the bituminous material specifications (ASTM D5-13; ASTM D36-20; ASTM D1754-19).The penetration value and softening point are found to be 67.7 mm and 54.25 °C, where both fall into standard ranges (63–75 mm and 54–58 °C, respectively). In the thin-film oven test, the weight loss was 0.37%, which shows very good resistance to volatilization in hot mixing. Bulk specific gravity (1.03) are again in the comparable limits of 1.02–1.04 and indicate sufficient compaction and coating of aggregate by binder (Chakraborty *et al*. 2023).The results of further tests performed to find the ideal composition of the mix (Table 7) reveal that the best performance was achieved with the most asphalt content (5.53%), targeting maximum stability and minimum voids. Such findings reflect the potential of using molten slag as an asphalt aggregate in medium-traffic roads in the Kolkata Metropolitan Region and indicate that, through the valorisation of waste and conservation of resources, it may also be possible to create environmental and economic benefits (Ghosh and Das, 2022; CPCB, 2021).

CONCLUSION

The current study showed that incinerated hospital waste ash can be economically and technically stabilized by high-temperature melting to produce a chemically- and physically-stable molten slag. The resultant slag had a matrix dominated by silicates, with a composition of more than 53% SiO_2, 9% CaO and 16% Al_2O_3, confirming its suitability for heavy metals immobilization. The low concentrations of metals in the leachates of the slag from leaching tests were far below the maximum concentration limits of U.S.EPA., supporting nonhazardous classification of the product. In addition, the mechanical and physical properties of molten slag, including abrasive resistance, crushing value and angularity, met or exceeded the applicable standard specifications for road and asphalt aggregates. Thus, these results support the feasibility of using hospital waste molten slag as an environmentally friendly alternative to natural aggregate in road construction applications with a view to waste reduction, resource conservation, and sustainable infrastructure development. This makes the process a potentially useful circular-economy route for converting biowaste-derived wastes from a biomedical origin into useful construction products.

Table 1: Operational Specifications of the Hospital Waste Incinerator Plant in Kolkata, West Bengal

Parameter	Specification	Unit	Standard/Reference	Remarks
Operating Time	24	hours/day	CPCB Guidelines (2016)	Continuous operation for waste load management
Type of Fuel	Diesel	–	MoEF and CC, India (2016)	Used for stable combustion
Type of Feed	Segregated Hospital Waste	–	Bio-Medical Waste Rules, 2018	Includes pathological, plastic, and general waste
Treatment Capacity	500	kg/hour	CPCB Standard	Suitable for medium-sized hospitals
Amount of Flue Gas	20,000	m^3/hour	CPCB Standard (Stack Emission)	Based on waste calorific value

Amount of Slag Produced	~10	% of total feed	Derived value	Slag further tested for reuse potential
Temperature in Primary Chamber	950	°C	CPCB Guideline (Min. 800°C)	Ensures complete combustion
Temperature in Secondary Chamber	1200	°C	CPCB Guideline (Min. 1050°C)	Effective for dioxin/furan destruction
Air Pollution Control Device (APCD)	Venturi Scrubber + Bag Filter	–	CPCB Norms	Reduces particulate and acid gas emissions
Final Disposal Method	Slag Collection and Landfill	–	SWM Rules, 2016	Evaluated for reuse in road material

Table 5: Physical and mechanical properties of hospital waste molten slag as road aggregate substitutes

Property	Standard requirement	Test results (Mean ± SD)	Standard / Method Used	Remarks
Water absorption (%)	≤ 2.0	0.59 ± 0.03	ASTM C127	Excellent moisture resistance
Bulk density (g/cm³)	1.6 – 2.0	1.85 ± 0.04	ASTM C29	Comparable to natural stone aggregate
Angularity number	6 – 9	7.0 ± 1.42	MS 7.5	Optimum particle interlocking
Aggregate crushing value (%)	≤ 30	15.64 ± 2.70	BS 812 Part III	Within permissible limit
Aggregate impact value (%)	≤ 30	29.82 ± 4.90	BS 812 Part III	Satisfactory impact resistance
Los Angeles abrasion value (%)	≤ 30	25.01 ± 3.70	ASTM C131	Suitable for base and sub-base courses
Polished stone value	≥ 40	52.27 ± 8.90	BS 812 Part 114	High skid resistance
Soundness test (%)	≤ 15	10.57 ± 1.80	ASTM C88	Excellent weathering resistance
Moisture content (%)	≤ 1.0	0.42 ± 0.05	ASTM D2216	Stable under wet conditions
Flakiness index (%)	≤ 30	22.45 ± 2.64	IS: 2386 (Part 1)	Suitable shape for

				compaction
Elongation index (%)	≤ 35	27.31 ± 2.88	IS: 2386 (Part 1)	Acceptable gradation characteristics

Note: All data are means of six samples collected from the Kolkata hospital incineration slag site

Table 6: Asphalt binder properties using hospital waste molten slag

Asphalt Property	**Standard requirement**	**Test results (Mean ± SD)**	**Standard / Method Used**	**Performance Interpretation**
Penetration (mm)	63 – 75	67.7 ± 8.7	ASTM D5	Within standard range
Softening point (°C)	54 – 58	54.25 ± 5.9	ASTM D36	Meets required specification
Bulk specific gravity	1.02 – 1.04	1.03 ± 0.03	ASTM D70	Optimum density for mix design
Thin film oven test (weight loss %)	0.2 – 0.5	0.37 ± 0.01	ASTM D1754	Excellent aging resistance
Ductility (cm)	≥ 75	85.6 ± 4.2	ASTM D113	High flexibility
Flash point (°C)	≥ 220	245 ± 6.5	ASTM D92	Safe for hot mixing
Viscosity at 135°C (Pa·s)	0.28 – 0.35	0.31 ± 0.02	ASTM D4402	Good workability
Penetration index	−1.0 to +1.0	+0.35 ± 0.08	ASTM D5 / D36	Stable under temperature variations

Note: All data are means of six samples prepared with hospital waste molten slag binder composites.

Table 7: Mix design analysis and performance of asphalt with hospital waste molten slag

Parameter	**Value (Mean ± SD)**	**Standard reference / Method**	**Remarks**
Asphalt content at maximum density (%)	4.10 ± 1.04	Marshall Mix Design	Lower voids, good compaction
Asphalt content at maximum stability (%)	5.50 ± 1.87	ASTM D1559	Optimum strength and cohesion
Asphalt content at 3% air voids (%)	7.40 ± 2.14	ASTM D6927	Slightly higher binder content
Asphalt content for resilience modulus (%)	5.10 ± 1.02	ASTM D7369	Stable elasticity performance
Average (optimum) asphalt content (%)	5.53 ± 2.03	Derived mean	Ideal for medium-traffic roads
Marshall stability (kN)	≥ 8	10.25 ± 0.93	ASTM D1559
Flow value (mm)	2 – 4	3.2 ± 0.7	ASTM D6927
Voids in total mix (VTM, %)	3 – 5	4.1 ± 0.4	ASTM D3203
Voids filled with bitumen (VFB, %)	70 – 80	76.8 ± 2.3	ASTM D6927
Air voids in mineral aggregate (VMA, %)	≥ 14	15.2 ± 1.1	ASTM D2041

Note: All values represent mean results from six replicate asphalt–slag mixtures prepared for this study (Kolkata Metropolitan Region, West Bengal).

ABSTRACT

The Micro Topological Space was introduced by Chandrasekar. They studied its properties and characterizations. Also they introduced the concept of A New Class of Micro α^*-Generalized Closed Sets in Micro Topological Spaces and investigated some of its basic properties. The main goal of this work is to induct and study the properties of $\alpha^* g_{\mathcal{M}}$-Compact Space in Micro Topological Spaces and study its relationship with existing spaces. Further we obtain certain characterizations of these spaces.

Keywords: $\alpha^* g_{\mathcal{M}}$-closed, $\alpha^* g_{\mathcal{M}}$-open,$\alpha^* g_{\mathcal{M}}$-Compact Space and $\alpha^* g_{\mathcal{M}}$-Lindelof Space.

INTRODUCTION

Topology comprises one of the oldest and most significant topics of Mathematics; the idea of Topology is becoming vaster and more complex by the day. Several versions of Topologies have recently been developed until now. The concept of Nano Topology was introduced by Lellis Thivagar in 2013. Micro Topology was an expansion of Nano Topology. S.Chandrasekar introduced and researched Micro Semi open, Micro Pre open, Micro Semi continuous and Micro Pre continuous in Micro Topological Spaces. R.Anandhi and N. Balamani invented the idea of Micro α-Generalised Closed Sets on Micro Topological Spaces and investigated the corresponding Micro separation axioms. A New Class of Micro Generalized Closed Sets in Micro Topological Spaces, that is, $\alpha^* g_{\mathcal{M}}$-Closed Sets is introduced by

P.Anbarasi Rodrigo and K.Selvakumari Prasha. The purpose of this paper was too introduced and analyzed the concepts of as $\alpha^* g_{\mathcal{M}}$-Compact Space, in Micro Topological Spaces. Some of the basic properties of $\alpha^* g_{\mathcal{M}}$-Compact Space are analyzed.

PRELIMINARIES:

In this portion, we review a few essential Micro Topological Spaces definitions and outcomes that will be important in the sequel.

Definition: 2.1 Let $\mathbb{U}\neq\phi$, finite class of elements known as universe & $\mathcal{R}$ denotes the equivalence relation in $\mathbb{U}$ termed as indiscernibility relation. Therefore $\mathbb{U}$ is parted into distinct equivalence classes. Object from same equivalence class has been named as indiscernible with one another. And $(\mathbb{U},\mathcal{R})$, the pair is approximation space. Take $\mathbb{X}\subseteq_{\mathcal{M}}\mathbb{U}$.

1) The lower Approximation of $\mathbb{X}$ in regards to $\mathcal{R}$ would be the class of entire elements, that could be for certain classified as $\mathbb{X}$in terms of $\mathcal{R}$ which is notated as $\mathbb{L}_{\mathcal{R}}(\mathbb{X})$. i.e.$\mathbb{L}_{\boldsymbol{\mathcal{R}}}(\mathbb{X})=\cup_{\mathbb{X}\in\mathbb{U}}\{\mathcal{R}(\mathbb{X}):\mathcal{R}(\mathbb{X})\subseteq_{\mathcal{M}}\mathbb{X}\}$, here $\mathcal{R}(\mathbb{X})$ refer the equivalence class gained by $\mathbb{X}\in\mathbb{U}$.
2) The upper Approximation of $\mathbb{X}$ under $\mathcal{R}$ would be the class of elements, which could be possibly characterized as $\mathbb{X}$ by $\mathcal{R}$ & notated by $\mathbb{U}_{\mathcal{R}}(\mathbb{X})$. i.e.$\mathbb{U}_{\mathcal{R}}(\mathbb{X})= \cup_{\mathbb{X}\in\mathbb{U}}\{\mathcal{R}(\mathbb{X}):\mathcal{R}(\mathbb{X})\cap\mathbb{X}\neq\phi\}$.
3) The boundary area of $\mathbb{X}$ in regards to $\mathcal{R}$ is the class of elements, that could be specified neither as $\mathbb{X}$ nor as not $\mathbb{X}$ in regards with $\mathcal{R}$ & notated by $\mathbb{B}_{\boldsymbol{\mathcal{R}}}(\mathbb{X})$. i.e. $\mathbb{B}_{\boldsymbol{\mathcal{R}}}(\mathbb{X})=\mathbb{U}_{\boldsymbol{\mathcal{R}}}(\mathbb{X})-\mathbb{L}_{\boldsymbol{\mathcal{R}}}(\mathbb{X})$.

Definition: 2.2 Consider universe $(\mathbb{U},\mathcal{R})$**,** equivalence relation in $\mathbb{U}$ & $\tau_{\mathcal{R}}(\mathbb{X})=\{\mathbb{U},\phi,\mathbb{L}_{\boldsymbol{\mathcal{R}}}(\mathbb{X}), \mathbb{U}_{\boldsymbol{\mathcal{R}}}(\mathbb{X}),\mathbb{B}_{\mathcal{R}}(\mathbb{X})\}$, here $\mathbb{X}\subseteq_{\mathcal{M}}\mathbb{U}$. So that $\tau_{\boldsymbol{\mathcal{R}}}(\mathbb{X})$ fulfills the below criteria:

1) $\mathbb{U}\&\phi\in\tau_{\boldsymbol{\mathcal{R}}}(\mathbb{X})$.
2) The union of objects from the sub-classes of $\tau_{\mathcal{R}}(\mathbb{X})$ lies in $\tau_{\boldsymbol{\mathcal{R}}}(\mathbb{X})$.
3) The intersection of object of any finite sub-classes of $\tau_{\mathcal{R}}(\mathbb{X})$ lies in $\tau_{\boldsymbol{\mathcal{R}}}(\mathbb{X})$.

i.e., $\tau_{\mathcal{R}}(\mathbb{X})$ is a Topology in $\mathbb{U}$said as Nano Topology on $\mathbb{U}$in regards to $\mathbb{X}$. $(\mathbb{U},\tau_{\mathcal{R}}(\mathbb{X}))$ termed as Nano Topological Space. Object from $\tau_{\mathcal{R}}(\mathbb{X})$ are the Nano open sets and its complements is Nano closed sets.

Definition: 2.3 [2] Consider $(\mathbb{U},\tau_{\mathcal{R}}(\mathbb{X}))$, an Nano Topological Spaces. So $\mu_{\boldsymbol{\mathcal{R}}}(\mathbb{X})=\{\mathbb{N}\cup(\mathbb{N}'\cap\mu)\text{: }\mathbb{N},\mathbb{N}'\in\tau_{\mathcal{R}}(\mathbb{X})\}$ & it is referred as Micro Topology of $\tau_{\mathcal{R}}(\mathbb{X})$ and $\mu\notin\tau_{\mathcal{R}}$meet the given axioms:

1) $\mathbb{U},\phi\in\mu_{\mathcal{R}}(\mathbb{X})$.
2) The union of objects from the Sub-classes of $\mu_{\mathcal{R}}(\mathbb{X})$ lies in $\mu_{\boldsymbol{\mathcal{R}}}(\mathbb{X})$.
3) The intersection of objects from any finite sub-classes of $\mu_{\boldsymbol{\mathcal{R}}}(\mathbb{X})$ lies in $\mu_{\mathcal{R}}(\mathbb{X})$.

So $\mu_{\boldsymbol{\mathcal{R}}}(\mathbb{X})$ is said as the Micro Topological on $\mathbb{U}$ in regards to $\mathbb{X}$. $(\mathbb{U},\tau_{\mathcal{R}}(\mathbb{X}),\mu_{\mathcal{R}}(\mathbb{X}))$ is termed as Micro Topological Spaces and objects from $\mu_{\boldsymbol{\mathcal{R}}}(\mathbb{X})$ are the Micro open & its complement is termed as a Micro closed sets.

Definition: 2.4 [1] Consider $(\mathbb{U},\tau_{\mathcal{R}}(\mathbb{X}), \mu_{\mathcal{R}}(\mathbb{X}))$ a Micro Topological Spaces. A subset $\mathbb{A}$ of $\mathbb{U}$is said to be $\alpha^* g_{\mathcal{M}}$-closed set if $\mathcal{M}\alpha^*\text{cl}(\mathbb{A})\subseteq_{\mathcal{M}}\text{int}\mathbb{U}$, whence $\mathbb{A}\subseteq_{\mathcal{M}}\mathbb{U}$ & $\mathbb{U}$ is a Micro α-open in $\mathbb{U}$.

Result: 2.5 [1] Every $\mathcal{M}$-closed is $\alpha^* g_{\mathcal{M}}$-closed.

Definition: 2.6 Let $(\mathbb{U},\tau_{\boldsymbol{\mathcal{R}}}(\mathbb{X}),\mu_{\boldsymbol{\mathcal{R}}}(\mathbb{X}))$ and $(\mathbb{V},\tau_{\boldsymbol{\mathcal{R}}}{}^{\star}(\mathbb{M}),\mu^{\star}{}_{\boldsymbol{\mathcal{R}}}(\mathbb{M}))$ be two Micro Topological Spaces.

1) A function $\mathbb{F}:\mathbb{U}\to\mathbb{V}$ is called $\alpha^* g_{\mathcal{M}}$-continuous functions if the inverse image of every$\alpha^* g_{\mathcal{M}}$-closed in $\mathbb{U}$ is Micro closed in $\mathbb{V}$.
2) A function $\mathbb{F}:\mathbb{U}\to\mathbb{V}$ is called $\alpha^* g_{\mathcal{M}}$-irresolute function if $\mathbb{F}^{-1}(\mathbb{S})$ is $\alpha^* g_{\mathcal{M}}$-closed in $\mathbb{U}\ \forall\ \alpha^* g_{\mathcal{M}}$-closed in $\mathbb{V}$.
3) A function $\mathbb{F}:\mathbb{U}\to\mathbb{V}$ is called strongly $\alpha^* g_{\mathcal{M}}$-continuous function if the inverse image of every $\alpha^* g_{\mathcal{M}}$-closed in $\mathbb{V}$ is Micro closed in $\mathbb{U}$.
4) A function $\mathbb{F}:\mathbb{U}\to\mathbb{V}$ is called totally $\alpha^* g_{\mathcal{M}}$-continuous function if inverse image of every Micro closed in $\mathbb{V}$ is$\alpha^* g_{\mathcal{M}}$-clopen in $\mathbb{U}$.
5) A function $\mathbb{F}:\mathbb{U}\to\mathbb{V}$ is called perfectly $\alpha^* g_{\mathcal{M}}$-continuous function if inverse image of every$\alpha^* g_{\mathcal{M}}$-closed in $\mathbb{V}$ is Micro clopen in $\mathbb{U}$.

6) A function $\mathbb{F}:\mathbb{U}\to\mathbb{V}$ is called slightly $\alpha^*g_{\mathcal{M}}$-continuous function if inverse image of every Micro clopen in $\mathbb{V}$ is $\alpha^*g_{\mathcal{M}}$-closed in $\mathbb{U}$.

Definition: 2.7 A Micro topological Spaces $(\mathbb{U},\tau_{\mathcal{R}}(\mathbb{X}),\mu_{\mathcal{R}}(\mathbb{X}))$ is said to be $\alpha^*g_{\mathcal{M}}\mathcal{T}_{1/2}$-space or $\alpha^*g_{\mathcal{M}}$-space if every $\alpha^*g_{\mathcal{M}}$-closed in $\mathbb{U}$ is Micro closed in $\mathbb{U}$.

III: $\alpha^*g_{\mathcal{M}}$-COMPACT SPACES

Definition: 3.1 A collection $\{\mathcal{A}_i:i\in\mathcal{I}\}$ of Micro open sets in a Micro topological Spaces $\mathbb{U}$ is called a Micro open cover of a subset $\mathcal{B}$ of $\mathbb{U}$ if $\mathcal{B}\subseteq_{\mathcal{M}}\{\mathcal{A}_i:i\in\mathcal{I}\}$ holds.

Definition: 3.2 A Micro topological space $\mathbb{U}$ is called Micro compact if every Micro open cover of $\mathbb{U}$ has a finite sub cover.

Definition: 3.3 A subset $\mathcal{B}$ of a Micro Topological Space $\mathbb{U}$ is said to be Micro compact relative to $\mathbb{U}$ if for every collection $\{\mathcal{A}_i:i\in\mathcal{I}\}$ of Micro open subsets of $\mathbb{U}$ such that $\mathcal{B}\subseteq_{\mathcal{M}}\{\mathcal{A}_i:i\in\mathcal{I}\}$ there exists a finite subset $\mathcal{I}_0$ of $\mathcal{I}$ such that $\mathcal{B}\subseteq_{\mathcal{M}}\{\mathcal{A}_i:i\in\mathcal{I}_0\}$.

Definition: 3.4 A subset $\mathcal{B}$ of a Micro Topological Space $\mathbb{U}$ is said to be Micro compact if $\mathcal{B}$ is Micro compact as a subspace of $\mathbb{U}$.

Definition 3.5 A Micro Topological Space $\mathbb{U}$ is said to be Micro Lindelof Space if every Micro open cover of $\mathbb{U}$ has countable subcover.

Definition: 3.6 A collection $\{\mathcal{A}_i:i\in\mathcal{I}\}$ of $\alpha^*g_{\mathcal{M}}$-open sets in a Micro Topological Spaces $\mathbb{U}$ is called a $\alpha^*g_{\mathcal{M}}$-open cover of a subset $\mathcal{B}$ of $\mathbb{U}$ if $\mathcal{B}\subseteq_{\mathcal{M}}\{\mathcal{A}_i:i\in\mathcal{I}\}$ holds.

Definition: 3.7 A Micro topological space $\mathbb{U}$ is called $\alpha^*g_{\mathcal{M}}$-compact if every $\alpha^*g_{\mathcal{M}}$-open cover of $\mathbb{U}$ has a finite sub cover.

Definition: 3.8 A subset $\mathcal{B}$ of a Micro Topological Space $\mathbb{U}$ is said to be $\alpha^*g_{\mathcal{M}}$-compact relative to $\mathbb{U}$ if for every collection $\{\mathcal{A}_i:i\in\mathcal{I}\}$ of $\alpha^*g_{\mathcal{M}}$-open subsets of $\mathbb{U}$ such that $\mathcal{B}\subseteq_{\mathcal{M}}\{\mathcal{A}_i:i\in\mathcal{I}\}$ there exists a finite subset $\mathcal{I}_0$ of $\mathcal{I}$ such that $\mathcal{B}\subseteq_{\mathcal{M}}\{\mathcal{A}_i:i\in\mathcal{I}_0\}$.

Definition: 3.9 A subset $\mathcal{B}$ of a Micro Topological Space $\mathbb{U}$ is said to be $\alpha^*g_{\mathcal{M}}$-compact if $\mathcal{B}$ is $\alpha^*g_{\mathcal{M}}$-compact as a subspace of $\mathbb{U}$.

Definition 3.10 A Micro Topological Space $\mathbb{U}$ is said to be $\alpha^*g_{\mathcal{M}}$-Lindelof Space if every $\alpha^*g_{\mathcal{M}}$-open cover of $\mathbb{U}$ has countable subcover.

Theorem: 3.11 Every Micro compact Space is $\alpha^*g_{\mathcal{M}}$-compact Space.

Proof: Let $\{\mathcal{A}_i:i\in\mathcal{I}\}$ be a Micro open cover of $\mathbb{U}$. Since every Micro open set is $\alpha^*g_{\mathcal{M}}$-open. So $\{\mathcal{A}_i:i\in\mathcal{I}\}$ is a $\alpha^*g_{\mathcal{M}}$-open cover of $\mathbb{U}$. Since $\mathbb{U}$ is Micro compact, Micro open cover $\{\mathcal{A}_i:i\in\mathcal{I}\}$ of has a finite sub cover say $\{\mathcal{A}_i:i=1,2,3,\ldots\ldots,n\}$ for $\mathbb{U}$. Thus $\{\mathcal{A}_i:i\in\mathcal{I}\}$ is a $\alpha^*g_{\mathcal{M}}$-open cover of $\mathbb{U}$. Hence $\mathbb{U}$ is $\alpha^*g_{\mathcal{M}}$-compact Space.

Remark: 3.12 Vice versa of the theorem are not true.

Remark: 3.13 The above remark 3.12 is true if $\mathbb{U}$ is $\alpha^*g_{\mathcal{M}}\mathcal{T}_{1/2}$-space.

Theorem: 3.14 Every $\alpha^*g_{\mathcal{M}}$-compact Space is $\alpha^*g_{\mathcal{M}}$-Lindelof Space.

Proof: Let $\mathbb{U}$ be $\alpha^*g_{\mathcal{M}}$-compact. Let $\{\mathcal{A}_i:i\in\mathcal{I}\}$ be a $\alpha^*g_{\mathcal{M}}$-open cover of $\mathbb{U}$. Then $\{\mathcal{A}_i:i\in\mathcal{I}\}$ has a finite sub-cover $\{\mathcal{A}_i:i=1,2,3,\ldots\ldots,n\}$. Since $\mathbb{U}$ is $\alpha^*g_{\mathcal{M}}$-compact. Since every finite sub-cover gives a countable sub-cover. That is $\{\mathcal{A}_i:i=1,2,3,\ldots\ldots,n\}$, is countable sub-cover of $\{\mathcal{A}_i:i\in\mathcal{I}\}$ for $\mathbb{U}$. Thus $\mathbb{U}$ is $\alpha^*g_{\mathcal{M}}$-Lindelof space.

Remark: 3.15 Vice versa of the theorem are not true.

Theorem 3.16 A $\alpha^* g_{\mathcal{M}}$-continuous image of $\alpha^* g_{\mathcal{M}}$-Lindelof Space is $\alpha^* g_{\mathcal{M}}$-Lindelof.
Proof: Let $\{\mathcal{A}_i : i \in \mathcal{I}\}$ for each be a $\alpha^* g_{\mathcal{M}}$-open cover of $\mathbb{U}$ of $\alpha^* g_{\mathcal{M}}$-continuous $\mathbb{F}:\mathbb{U}\to\mathbb{V}$ from a $\alpha^* g_{\mathcal{M}}$-Lindelof space. Here $\mathbb{F}^{-1}(\mathcal{A}_i): i \in \mathcal{I}\}$ is $\alpha^* g_{\mathcal{M}}$-open cover of $\mathbb{U}$ and it has a countable subcover $\mathbb{F}^{-1}(\{\mathcal{A}_i : i = 1,2,3, \ldots\ldots\ldots, n\})$ as $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-Lindelof Space. Now $\mathbb{F}(\mathbb{U}) = \mathbb{V}=\cup_{i\in\mathcal{I}}[\mathcal{A}_i : i \in \mathcal{I}]$ as $\mathbb{U}=\cup_{i\in\mathcal{I}}\mathbb{F}^{-1}(\mathcal{A}_i)$ where $\mathcal{A}_1, \mathcal{A}_1, \ldots\ldots\ldots \mathcal{A}_n$is a countable subfamily of $\{\mathcal{A}_i : i \in \mathcal{I}\}$. Therefore $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-Lindelof Space.

Theorem 3.17 If $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-Lindelof Space and countably $\alpha^* g_{\mathcal{M}}$-compact space, then $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-compact.
Proof: Assume $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-Lindelof Space and countably $\alpha^* g_{\mathcal{M}}$-compact. Let $\{\mathcal{A}_i : i \in \mathcal{I}\}$ be a $\alpha^* g_{\mathcal{M}}$-open cover of $\mathbb{U}$. Since $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-Lindelof Space, then $\{\mathcal{A}_i : i \in \mathcal{I}\}$ has countable subcover $\{\mathcal{A}_i : i \in \mathcal{I}\}$. Again, since $\mathbb{U}$ is countably $\alpha^* g_{\mathcal{M}}$-compact, $\{\mathcal{A}_i : i \in \mathcal{I}\}$ has a finite subcover $\{\mathcal{A}_i : i$=1,2,3,……..,n}. Hence, $\{\mathcal{A}_i : i$=1,2,3,……..,n} a finite subcover of $\{\mathcal{A}_i : i \in \mathcal{I}\}$ for $\mathbb{U}$. Thus $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-compact Space.

Theorem: 3.18 A $\alpha^* g_{\mathcal{M}}$-continuous image of a $\alpha^* g_{\mathcal{M}}$-compact Space is a Micro compact.
Proof: Assume $\mathbb{F}:\mathbb{U}\to\mathbb{V}$ be a $\alpha^* g_{\mathcal{M}}$-continuous from a $\alpha^* g_{\mathcal{M}}$-compact $\mathbb{U}$ onto a Micro Topological Space $\mathbb{V}$. Let $\mathbb{S}=\{\mathcal{A}_i : i \in \mathcal{I}\}$ be a Micro open cover of $\mathbb{V}$. Therefore $\mathbb{F}^{-1}(\mathbb{S})=\{\mathbb{F}^{-1}(\mathcal{A}_i): i \in \mathcal{I}\}$ is a $\alpha^* g_{\mathcal{M}}$-open cover of $\mathbb{U}$, as $\mathbb{F}$ is $\alpha^* g_{\mathcal{M}}$-continuous. Since $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-compact Space, the $\alpha^* g_{\mathcal{M}}$-open cover $\mathbb{F}^{-1}(\mathbb{S})=\{\mathbb{F}^{-1}(\mathcal{A}_i): i \in \mathcal{I}\}$ of $\mathbb{U}$, has a finite sub cover say $\{\mathbb{F}^{-1}(\mathcal{A}_i): i = 1,2,3, \ldots\ldots\ldots, n\}\}$. Therefore $\mathbb{U}=\cup_{i\in\mathcal{I}}\mathbb{F}^{-1}(\mathcal{A}_i)$, which implies $\mathbb{V}=\mathbb{F}(\mathbb{U})=\cup_{i\in\mathcal{I}}\mathcal{A}_i$. That is $\{\mathcal{A}_i : i = 1,2,3, \ldots\ldots\ldots, n\}$ is a finite sub cover of $\mathbb{V}$. Hence $\mathbb{V}$ is Micro compact.

Theorem: 3.19 A $\alpha^* g_{\mathcal{M}}$-continuous image of a $\alpha^* g_{\mathcal{M}}$-compact Space is a $\alpha^* g_{\mathcal{M}}$-compact.
Proof: The proof the theorem follows similar approach as theorem 3.18 respectively.

Theorem: 3.20 The image of a $\alpha^* g_{\mathcal{M}}$-compact Space under a surjective and $\alpha^* g_{\mathcal{M}}$-irresolute is $\alpha^* g_{\mathcal{M}}$-compact Space.
Proof: Assume $\mathbb{F}:\mathbb{U}\to\mathbb{V}$ be a $\alpha^* g_{\mathcal{M}}$-irresolute, surjective and $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-compact Space. Let $\{\mathcal{A}_i : i \in \mathcal{I}\}$ be a$\alpha^* g_{\mathcal{M}}$-open cover of $\mathbb{V}$. Since $\mathbb{F}$ is $\alpha^* g_{\mathcal{M}}$-irresolute, $\mathbb{F}^{-1}(\{\mathcal{A}_i : i \in \mathcal{I}\})$ forms a $\alpha^* g_{\mathcal{M}}$-open cover of $\mathbb{U}$. Since $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-compact Space, it has a finite subcover say $\mathbb{F}^{-1}(\{\mathcal{A}_i : i = 1,2,3, \ldots\ldots\ldots, n\})$. The surjective of $\mathbb{F}$ implies $\{\mathcal{A}_i : i = 1,2,3, \ldots\ldots\ldots, n\}$ is a finite subcover of $\mathbb{V}$. Hence $\mathbb{V}$ is $\alpha^* g_{\mathcal{M}}$-compact Space.

Theorem: 3.21 If $\mathbb{F}:\mathbb{U}\to\mathbb{V}$ is a bijective, $\alpha^* g_{\mathcal{M}}$-open map and $\alpha^* g_{\mathcal{M}}$-irresolute, then the image of $\alpha^* g_{\mathcal{M}}$-compact Space is Micro compact Space.
Proof: Assume $\mathbb{F}:\mathbb{U}\to\mathbb{V}$ be a $\alpha^* g_{\mathcal{M}}$-irresolute, bijective, $\alpha^* g_{\mathcal{M}}$-open map and $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-compact Space. Let $\{\mathcal{A}_i : i \in \mathcal{I}\}$ be a Micro open cover of $\mathbb{V}$. Since $\mathbb{F}$ is $\alpha^* g_{\mathcal{M}}$-open map, $\mathbb{F}(\{\mathcal{A}_i : i \in \mathcal{I}\})$ forms a $\alpha^* g_{\mathcal{M}}$-open cover of $\mathbb{U}$. Since $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-compact Space, it has a finite subcover say $\mathbb{F}^{-1}(\{\mathcal{A}_i : i = 1,2,3, \ldots\ldots\ldots, n\})$. Since $\mathbb{F}$ is bijective and $\alpha^* g_{\mathcal{M}}$-irresolute, $\mathbb{F}^{-1}(\mathbb{F}(\{\mathcal{A}_i : i = 1,2,3, \ldots\ldots\ldots, n\}))$ forms a finite subcover of $\mathbb{U}$. Hence $\mathbb{V}$ is Micro compact Space.

Theorem: 3.22 If $\mathbb{F}:\mathbb{U}\to\mathbb{V}$ is a bijective, strongly $\alpha^* g_{\mathcal{M}}$-open map and $\alpha^* g_{\mathcal{M}}$-irresolute, then the image of $\alpha^* g_{\mathcal{M}}$-compact Space is $\alpha^* g_{\mathcal{M}}$-compact Space.
Proof: Assume $\mathbb{F}:\mathbb{U}\to\mathbb{V}$ be a $\alpha^* g_{\mathcal{M}}$-irresolute, bijective, $\alpha^* g_{\mathcal{M}}$-open map and $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-compact Space $\mathbb{U}$ onto a Micro Topological Space $\mathbb{V}$. Let $\{\mathcal{A}_i : i \in \mathcal{I}\}$ be a$\alpha^* g_{\mathcal{M}}$-open cover of $\mathbb{V}$. Since $\mathbb{F}$ is strongly $\alpha^* g_{\mathcal{M}}$-open map, $\mathbb{F}(\{\mathcal{A}_i : i \in \mathcal{I}\})$ forms a $\alpha^* g_{\mathcal{M}}$-open cover of $\mathbb{U}$. Since $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-compact Space, it has a finite subcover say $\mathbb{F}^{-1}(\{\mathcal{A}_i : i = 1,2,3, \ldots\ldots\ldots, n\})$. Since $\mathbb{F}$ is bijective and $\alpha^* g_{\mathcal{M}}$-irresolute, $\mathbb{F}^{-1}(\mathbb{F}(\{\mathcal{A}_i : i = 1,2,3, \ldots\ldots\ldots, n\}))$ forms a finite subcover of $\mathbb{U}$. Hence $\mathbb{V}$ is $\alpha^* g_{\mathcal{M}}$-compact Space.

Theorem: 3.23 Every $\alpha^* g_{\mathcal{M}}$-closed set of a $\alpha^* g_{\mathcal{M}}$-compact Space $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-compact Space relative to $\mathbb{U}$.
Proof: Let $\mathcal{A}$ be a $\alpha^* g_{\mathcal{M}}$-closed set of $\alpha^* g_{\mathcal{M}}$-compact Space $\mathbb{U}$. Then $\mathcal{A}^c$ is a $\alpha^* g_{\mathcal{M}}$-open in $\mathbb{U}$. Let $\{\mathcal{A}_i : i \in \mathcal{I}\}$ be a Micro open cover of $\mathcal{A}$ by$\alpha^* g_{\mathcal{M}}$-open sets of $\mathbb{U}$. Then $\{\mathcal{A}_i : i \in \mathcal{I}\} \cup \mathcal{A}^c$ forms a $\alpha^* g_{\mathcal{M}}$-open cover of $\mathbb{U}$. Since $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-compact Space, it has a finite subcover say $\{\mathcal{A}_i : i = 1,2,3, \ldots\ldots\ldots, n\} \cup \mathcal{A}^c$. Thus the $\alpha^* g_{\mathcal{M}}$-open cover of $\{\mathcal{A}_i : i \in \mathcal{I}\}$ of $\mathcal{A}$ contains a finite subcover $\{\mathcal{A}_i : i = 1,2,3, \ldots\ldots\ldots, n\}$. Hence $\mathcal{A}$ is $\alpha^* g_{\mathcal{M}}$-compact Space relative to $\mathbb{U}$.

Theorem: 3.24 A function $\mathbb{F}:\mathbb{U}\to\mathbb{V}$ is strongly $\alpha^* g_{\mathcal{M}}$-continuous from a $\alpha^* g_{\mathcal{M}}$-compact Space $\mathbb{U}$ onto a Micro Topological Space $\mathbb{V}$. Then $\mathbb{V}$ is $\alpha^* g_{\mathcal{M}}$-compact Space.
Proof: Assume $\mathbb{F}:\mathbb{U}\to\mathbb{V}$ be a strongly $\alpha^* g_{\mathcal{M}}$-continuous from a $\alpha^* g_{\mathcal{M}}$-compact $\mathbb{U}$ onto a Micro Topological Space $\mathbb{V}$. Let $\mathbb{S}=\{\mathcal{A}_i: i\in\mathcal{I}\}$ be a $\alpha^* g_{\mathcal{M}}$-open cover of $\mathbb{V}$. Therefore $\mathbb{F}^{-1}(\mathbb{S}) =\{\mathbb{F}^{-1}(\mathcal{A}_i): i \in \mathcal{I}\}$ is a Micro open cover of $\mathbb{U}$, as $\mathbb{F}$ is strongly $\alpha^* g_{\mathcal{M}}$-continuous. Since $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-compact Space, the $\alpha^* g_{\mathcal{M}}$-open cover $\mathbb{F}^{-1}(\mathbb{S})=\{\mathbb{F}^{-1}(\mathcal{A}_i): i \in \mathcal{I}\}$ of $\mathbb{U}$, has a finite sub cover say $\{\mathbb{F}^{-1}(\mathcal{A}_i): i = 1,2,3,\dots\dots,n\}$. Therefore $\mathbb{U}=\bigcup_{i\in\mathcal{I}}\mathbb{F}^{-1}(\mathcal{A}_i)$, which implies $\mathbb{V}=(\mathbb{U})=\bigcup_{i\in\mathcal{I}}\mathcal{A}_i$. That is $\{\mathcal{A}_i: i=1,2,3,\dots\dots\dots,n\}$ is a finite sub cover of $\mathbb{S}=\{\mathcal{A}_i: i\in\mathcal{I}\}$. Hence $\mathbb{V}$ is Micro compact.

Theorem: 3.25 A function $\mathbb{F}:\mathbb{U}\to\mathbb{V}$ is totally $\alpha^* g_{\mathcal{M}}$-continuous from a $\alpha^* g_{\mathcal{M}}$-compact Space $\mathbb{U}$ onto a Micro Topological Space $\mathbb{V}$. Then $\mathbb{V}$ is $\alpha^* g_{\mathcal{M}}$-compact Space.
Proof: The proof the theorem follows similar approach as theorem 3.24 respectively.

Theorem: 3.26 A function $\mathbb{F}:\mathbb{U}\to\mathbb{V}$ is slightly $\alpha^* g_{\mathcal{M}}$-continuous from a $\alpha^* g_{\mathcal{M}}$-compact Space $\mathbb{U}$ onto a Micro Topological Space $\mathbb{V}$. Then $\mathbb{V}$ is $\alpha^* g_{\mathcal{M}}$-compact Space.
Proof: The proof the theorem follows similar approach as theorem 3.24 respectively.

Theorem: 3.27 A function $\mathbb{F}:\mathbb{U}\to\mathbb{V}$ is perfectly $\alpha^* g_{\mathcal{M}}$-continuous from a $\alpha^* g_{\mathcal{M}}$-compact Space $\mathbb{U}$ onto a Micro Topological Space $\mathbb{V}$. Then $\mathbb{V}$ is $\alpha^* g_{\mathcal{M}}$-compact Space.
Proof: The proof the theorem follows similar approach as theorem 3.24 respectively.

Theorem: 3.28 If $\mathbb{U}$ is Micro compact and every $\alpha^* g_{\mathcal{M}}$-closed set in $\mathbb{U}$ is a Micro closed in $\mathbb{U}$, then $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-compact Space.
Proof: Let $\{\mathcal{A}_i: i\in\mathcal{I}\}$ be a $\alpha^* g_{\mathcal{M}}$-open cover of $\mathbb{U}$. Since every $\alpha^* g_{\mathcal{M}}$-closed set in $\mathbb{U}$ is a Micro closed in $\mathbb{U}$. Thus $\{\mathbb{U}-\mathcal{A}_i: i\in\mathcal{I}\}$ is a Micro closed cover of $\mathbb{U}$ and hence $\{\mathcal{A}_i: i\in\mathcal{I}\}$ is an Micro open cover of $\mathbb{U}$. Since $\mathbb{U}$ is Micro compact, there exists a finite sub cover $\{\mathcal{A}_i: i=1,2,3,\dots\dots\dots,n\}$ of $\{\mathcal{A}_i: i\in\mathcal{I}\}$ such that $\mathbb{U}=\bigcup_{i\in\mathcal{I}}(\mathcal{A}_i : i = 1,2,3,\dots\dots\dots, n)$. Hence $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-compact Space.

Theorem: 3.29 A $\alpha^* g_{\mathcal{M}}$-closed subset of a $\alpha^* g_{\mathcal{M}}$-compact Space $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-compact Space relative to $\mathbb{U}$.
Proof: Let $\mathcal{A}$ be a $\alpha^* g_{\mathcal{M}}$-closed subset of a Micro Topological Spaces $\mathbb{U}$. Then $\mathcal{A}^c$ is a $\alpha^* g_{\mathcal{M}}$-open in $\mathbb{U}$. Let $\mathbb{S}=\{\mathcal{A}_i: i\in\mathcal{I}\}$ be a open cover of $\mathcal{A}$ by$\alpha^* g_{\mathcal{M}}$-open subsets of $\mathbb{U}$. Then $\mathbb{T}=\mathbb{S}\cup\mathcal{A}^c$is a $\alpha^* g_{\mathcal{M}}$-open cover of $\mathbb{U}$. That is $\mathbb{U}=\bigcup_{i\in\mathcal{I}}\mathcal{A}_i \cup \mathcal{A}^c$. By hypothesis $\mathbb{U}$ is a $\alpha^* g_{\mathcal{M}}$-compact Space and hence $\mathbb{T}$ is reducible to a finite sub cover of $\mathbb{U}$ say $\mathbb{U}=\bigcup_{i\in\mathcal{I}}\mathcal{A}_i \cup \mathcal{A}^c$ for some finite subset $\mathcal{I}_0$ of $\mathcal{I}$. But $\mathcal{A}$ and $\mathcal{A}^c$ are disjoint. Hence $\subseteq_{\mathcal{M}}\{\mathcal{A}_i: i\in\mathcal{I}_0\}$. Thus $\alpha^* g_{\mathcal{M}}$-open cover $\mathbb{S}=\{\mathcal{A}_i: i\in\mathcal{I}\}$of $\mathcal{A}$ contains a finite subcover. Hence $\mathcal{A}$ is $\alpha^* g_{\mathcal{M}}$-compact Space, relative to $\mathbb{U}$.

Theorem: 3.30 A Micro Topological Space $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-compact Space if and only if every family of $\alpha^* g_{\mathcal{M}}$-closed sets of $\mathbb{U}$ having finite intersection property has a non empty intersection.
Proof: Assume $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-compact Space. Let $\{\mathcal{A}_i: i\in\mathcal{I}\}$ be a family $\alpha^* g_{\mathcal{M}}$-closed sets of $\mathbb{U}$ having finite intersection property. Suppose$\bigcap_{i\in\mathcal{I}}\mathcal{A}_i = \phi$. Then $\mathbb{U}-\bigcap_{i\in\mathcal{I}}\mathcal{A}_i = \mathbb{U}. \Longrightarrow \bigcap_{i\in\mathcal{I}}\mathcal{A}_i - \mathcal{A}_i = \mathbb{U}$. Thus $\mathbb{U}-\{\mathcal{A}_i: i \in \mathcal{I}\}$ is a $\alpha^* g_{\mathcal{M}}$-open cover of $\mathbb{U}$. Since $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-compact Space, it has a finite subcover say$\mathbb{U}-\{\mathcal{A}_i: i = 1,2,3,\dots\dots\dots, n\}$ and so $\bigcup[\mathbb{U}-\mathcal{A}_i: i = 1,2,3,\dots\dots\dots, n\}] = \bigcup_{i=1}^{n}[\mathbb{U}-\{\mathcal{A}_i: i = 1,2,3,\dots\dots\dots, n\}]$. This implies that $\mathbb{U}-\bigcap_{i=1}^{n}[\mathcal{A}_i: i = 1,2,3,\dots\dots\dots, n\}] = \mathbb{U}$ and hence we get $\bigcap_{i=1}^{n}[\mathcal{A}_i] = \phi$.This leads to contradicts, as $\{\mathcal{A}_i: i\in\mathcal{I}\}$ has a finite intersection property. Hence $\bigcap_{i\in\mathcal{I}}\mathcal{A}_i \neq \phi$. Conversely, Suppose $\mathbb{U}$ is not $\alpha^* g_{\mathcal{M}}$-compact Space. Then there exists a $\alpha^* g_{\mathcal{M}}$-open cover of $\mathbb{U}$ say $\{\mathcal{C}_i: i\in\mathcal{I}\}$ having no finite subcover. This implies that for any finite subfamily $\{\mathcal{C}_i: i=1,2,3,\dots\dots\dots,n\}$, $\bigcup_{i=1}^{n}[\mathbb{U}-\{\mathcal{C}_i: i \in \mathcal{I}\}]$. Thus the family $\mathbb{U}-\{\mathcal{C}_i: i \in \mathcal{I}\}$ of $\alpha^* g_{\mathcal{M}}$-closed sets has a finite intersection property. Then by our assumption, $\bigcap_{i\in\mathcal{I}}\mathbb{U}-\mathcal{C}_i \neq \phi$. This implies $\mathbb{U}-\bigcup_{i\in\mathcal{I}}\mathcal{C}_i \neq \phi$and so $\bigcup_{i\in\mathcal{I}}\mathcal{C}_i \neq \mathbb{U}$. Thus $\{\mathcal{C}_i: i\in\mathcal{I}\}$ is not a cover of $\mathbb{U}$ which is contradiction. Therefore there exists $\alpha^* g_{\mathcal{M}}$-open cover $\{\mathcal{A}_i: i\in\mathcal{I}\}$ of $\mathbb{U}$ has a finite subcover $\{\mathcal{A}_i: i = 1,2,3,\dots\dots\dots, n\}$. Hence $\mathbb{U}$ is $\alpha^* g_{\mathcal{M}}$-compact Space.

CONCLUSION

In this investigation, we looked into a few characteristics of Micro α^*-Generalized Closed Sets in Micro Topological Spaces. Also we introduced a $\alpha^* g_{\mathcal{M}}$-Compact Space. Micro Topology can be applied in analyze the properties of graphs and the relationships between vertices. Future research in Micro Topology holds significant potential in various fields, including data analysis and material science.

ABSTRACT

In this study, the effects of static stretching (SS) and myofascial release technique (MFR) on the flexibility of the calf muscles in football players under the age of fifteen are compared. A common cause of lower limb injuries in the high-intensity sport of football is muscular tension. Since limited ankle dorsiflexion is thought to be a risk factor for lower limb injuries, increasing flexibility is crucial for both preventing injuries and improving performance. Thirty volunteers with calf tightness were split into two groups for the study: Group A (MFR) and Group B (SS). While SS included extended, passive stretching exercises, MFR included continuous pressure and compression procedures aimed at the fascia. The Silfverskiold Test and the Visual Analogue Scale (VAS) were used to measure the results of pain and flexibility. The findings showed that MFR and SS both considerably increased calf flexibility and decreased pain, while MFR's impact on pain reduction was somewhat stronger. However, following a single session, neither intervention showed any lasting effects. Significant within-group improvements were validated by statistical analysis using paired and unpaired t-tests, but between-group comparisons revealed variations in pain reduction but not in flexibility. Both MFR and SS are useful therapies for improving flexibility and controlling discomfort in young football players, according to this study. To ascertain long-term benefits and the best intervention protocols, more research with longer follow-up is necessary.

Keywords: Myofascial release, Static stretching, Flexibility, Silfverskoild test.

INTRODUCTION

Soccer, known as football in most areas of the world, is one of the most popular and physically demanding games enjoyed by millions internationally. It involves high-intensity, intermittent, and non-continuous activities such as sprinting, jumping, cutting, pivoting, and kicking[1]. Due to these rapid motions, soccer players, especially young sportsmen, are prone to severe musculoskeletal problems. Among these, lower extremity injuries, including calf muscle strains, are prevalent and can significantly impact performance and career longevity[2]. Football is a popular sport nowadays because it is both a cutting-edge area of sports science and an exciting show for the general public. Football players compete in this unique sport, which requires not only precise physical balance and coordination but also the demonstration of strategic genius on the pitch [1]. Football is a world full of moves like quick runs, sudden stance changes, spectacular jumps, and lightning-fast ball-reactions. Football players must maintain optimal physical condition while skilfully directing and balancing their bodies due to the variety of actions and their high intensity[2]. Lack of muscular flexibility is one of the main causes of these injuries. Athletes are more susceptible to strains and other musculoskeletal disorders when their calf muscles are less flexible, which can also restrict ankle dorsiflexion and increase muscular stiffness. Therefore, increasing muscular flexibility is crucial for avoiding injuries and enhancing sports performance[3]. The gastrocnemius and soleus are the two primary muscles that make up the calf muscle. Some healthcare professionals refer to the gastrocnemius and soleus as a single, big muscle with two portions because these two muscles unite above the heel and link to the Achilles tendon. Because the gastrocnemius muscle attaches to both the knee and the ankle, strains of this muscle are frequent. Your tibia and fibula, the bones of your lower leg, are connected to the soleus [3]. The soleus muscles work in tandem with the gastrocnemius to support walking, running, and jumping. Additionally, it helps you maintain proper posture by supporting you with your legs. Players that are constantly crossing and shooting will have big calf muscles. Xherdan Shaqiri is among the better examples; he has some of the biggest calves in football, and he does have a very strong stroke [3,4]. Despite being a persistent injury with a poor response to therapy, there is little information on preventative measures for Achilles tendinopathy [4]. Achilles tendon injuries are linked to extended absences from sports, employment, and other activities, and they make up 2.4% of all injuries sustained by professional soccer players [5].

In addition to the decline in the athlete's health and performance, prevention is crucial because there is now no proven cure for Achilles tendinopathy [6]. The soleus and gastrocnemius tendons are put under more tension when ankle dorsiflexion is reduced. According to gait research, in a walking and running gait cycle, the soleus and gastrocnemius muscles absorb their maximum mechanical force right before toe-off [7]. Both the soleus and gastrocnemius muscles absorb more force when ankle dorsiflexion is restricted. Achilles tendinopathy might theoretically result from this persistently elevated strain. Reduced ankle dorsiflexion was linked to a 2.5–3.6 times increased incidence of Achilles tendinopathy, according to two prospective investigations [8,9]. Therefore, a wide range of medical specialists, including orthopaedic surgeons, sports physicians, and physiotherapists, test the ankle dorsiflexion angle. Football is a physically demanding and dynamic activity that puts a lot of strain on the ankles and lower limbs[10]. Football players are prone to injuries due to their frequent direction changes, abrupt accelerations, and explosive movements; among the most common disorders affecting this athletic population is chronic ankle instability (CAI) [11]. According to football players, CAI has the greatest rates of mechanical instability (38%) and repeated sprains (61%), respectively [12]. After an initial ankle sprain, CAI is a condition marked by recurrent bouts of giving way, discomfort, and a sense of joint instability[13]. An athlete's performance, agility, and risk of subsequent ankle sprains can all be negatively impacted by these symptoms, which frequently last past the acute injury phase[12,13]. Numerous treatment approaches have been put out to improve muscular flexibility; two popular ones are Myofascial Release (MFR) and Static Stretching (SS). A manual therapy method called Myofascial Release (MFR) uses prolonged pressure and stretching to release fascial limitations and increase range of motion. It seeks to improve tissue suppleness, relieve muscular tension, and release myofascial trigger points [14]. Conversely, Static Stretching (SS) is a technique used to improve range of motion and extensibility by maintaining a muscle in a

lengthened posture for an extended amount of time. Although these methods are often used in sports rehabilitation, it is unknown how successful they are in young football players[15]. Thus, the current study compares the effects of static stretching and myofascial release therapy on young football players' calf flexibility.

METHODOLOGY

From September 2024 to January 2025, an experimental research was carried out at the Ahmedabad Football Association (AFA), Ahmedabad. The Institutional Ethical Committee provided ethical approval. Using the convenience technique, 30 of the 48 participants were added to the research based on the inclusion criteria. Every participant gave their informed permission. Participants must be male or female, under the age of 15, have a trigger point at the gastrocnemius muscle, be willing to engage in the study, and have passive ankle dorsiflexion limited by at least 10 degrees [9,10]. were incorporated into the research. Recent trauma, lower limb operations, and any history of dislocation, fracture, or lower limb region. pathophysiology of the knee and ankle joints, Participants with neurologic conditions such as nerve entrapment, musculoskeletal injuries including bursitis, cysts, etc., tumours, and radiating pain were not included. The 15 participants in Group A will get treatment using the myofascial release method, whereas the 15 subjects in Group B will receive treatment using the static stretching approach. Participants underwent baseline measurements before to treatment, such as the Silfverskiold test's VAS for pain and flexibility, which will be acquired.

Myofascial Release Technique (Group A) [16,17]

The MFR group's participants were told to place their feet off the end of the treatment table and lie prone on it. The therapy started with the clinician bending the knee to 90 degrees and shaking the triceps surae group's abdominal muscles for 30 seconds. Following complete knee extension, MFR was conducted for one minute on the medial and lateral sides of the Achilles tendon and two minutes on the musculotendinous junction. The clinician's knuckles were used to provide wide strokes to loosen superficial constraints, and then their thumb was used to apply more targeted strokes to any limits that were found. With pressure applied from distal to proximal, strokes were given to the tissue at a 45-degree angle. In order to keep an eye on the severity of the therapy and make sure the participants were comfortable, the physician asked them to give comments. The physician shook the triceps surae complex's abdomen for 30 seconds at the conclusion of the session. All MFR treatments were administered by the same examiner (T.S.).

Group B: Technique for Static Stretching [18,19]

One plantar flexor stretch was done three times for 30 seconds each, with a 15-second break in between. This was known as static stretching. The individual will be in a supine position while the therapist stabilises the leg and holds it from the calcaneum to do this stretch. Continue to dorsiflex and extend the knee, pointing the toes in the direction of the head. Both groups performed the heel lift exercise, which is a standard calf muscle strength-building exercise. The heel lift exercise is frequently used to assess muscular strength and dynamic balance. With both legs and feet touching one another, the participants lift the job. The participants had to elevate their heels as fast as they could without losing their balance, and then naturally lower their feet [20,21].

Data Analysis

The 30 subjects were assessed using the Visual Analogue Scale (VAS) for discomfort and the Silfverskiold test for range of motion. Data from before and after were examined. Data analysis was done using Microsoft Excel and SPSS version 26. The normalcy was examined using the Shapiro-Wilk test. The mean and standard deviations of the intra- and inter-group analyses were compared using the independent t-test and the student paired t-test. The study's Confidence Interval was maintained at 95%. A significance threshold of less than 0.05 was maintained.

RESULTS

Age and Gender Distribution in Different Groups (Table 1).

In the present study, the mean age of participants was12.6 ± 1.29 years for group A and 12.86 ± 0.83 years for group B.

Within-Group Comparison of VAS and the Silfverskiold Test in Group A (Table 2).
Significant improvements were seen in all outcome measures, that is, the pre-pain on VAS was 6.80 ± 0.69 and post-pain was 2.83 ± 0.47, Pre-Calf muscle flexibility on the Silfverskiold Test was 9.88 ± 1.74 and post-Calf muscle flexibility was 11.53 ± 1.55 for group A.

Within-Group Comparison of VAS and the Silfverskiold Test in Group B (Table 3).
All outcome measures showed significant improvements: group B's pre-pain score on the VAS was 6.66 + 0.64 and post-pain score was 5.38 + 0.71; group B's pre-calf muscle flexibility score on the Silfverskiold Test was 8.9 + 1.54 and post-calf muscular flexibility score was 10.68 + 6.20.

Between-Groups Comparison of VAS and the Silverskiold Test (Table 4).
Both groups' between-group data were compared using the unpaired t-test. Group analyses for VAS revealed statistically significant differences, according to statistical data analyses. A non-significant impact was shown by the Silfverskiold test.

DISCUSSION

Myofascial release (MFR), according to Herzog MM *et al*., is a manual treatment method intended to reduce muscular tension, increase flexibility, and speed up recovery. MFR has drawn interest in football (soccer and American football) because to its possible advantages in lowering DOMS, enhancing performance, and averting injuries. Numerous types of MFR have been studied, such as vibration-assisted methods, foam rolling, and dynamic cupping, and the results have shown promise in improving muscle function and flexibility[13]. According to Walls RJ *et al*., participants' calf muscular flexibility was considerably increased by both MFR and SS. In contrast to SS, MFR showed a somewhat higher gain in flexibility. This result is consistent with other research indicating that MFR improves range of motion (ROM) via increasing muscle flexibility and lowering fascial limitations. MFR's improved effectiveness over SS may be explained by its mechanical and neurophysiological effects, which include lower pain perception, increased blood flow, and lessened muscular tension[11]. The fact that MFR can target the calf muscle's fascial and muscular components may be one reason for its exceptional efficacy. Because football players do repetitive explosive motions like running and kicking, they typically develop muscular stiffness. More effective than SS alone, MFR may aid in the release of fascial adhesions and increase tissue mobility, improving overall flexibility (Ugbolue, U.C., 21). According to Muir IW *et al*., static stretching, a tried-and-true technique for increasing flexibility, also significantly increased the extensibility of the calf muscles. Since SS has long been known to lengthen muscle fibres and decrease stiffness, it is a crucial part of flexibility training. Nevertheless, SS's improvements in flexibility were marginally less noticeable than MFR's, perhaps as a result of its emphasis on passive extension rather than fascial limitations [17]. The application technique and duration are other important factors. According to Johnson EG *et al*., MFR uses rolling motions and continuous pressure to activate mechanoreceptors and enhance myofascial mobility, whereas SS mostly depends on holding a stretch for a long time to encourage muscle lengthening. This can result in a more noticeable and instantaneous increase in flexibility [19]. Stanek J. *et al*. Being flexible is crucial for young football players to avoid problems like Achilles tendonitis, muscular strains, and other lower limb dysfunctions. According to the study's findings, adding MFR exercises to warm-up and recovery regimens—like foam rolling or manual release therapy—may offer more advantages than static stretching alone [16]. This does not lessen the significance of SS, though, since it is still a useful technique for preserving long-term muscular flexibility. Age-related considerations should also be taken into account. Younger athletes' musculoskeletal development may

cause them to react differently to flexibility exercise. A thorough training program that incorporates both MFR and SS may offer a well-rounded strategy for improving flexibility. Notwithstanding the encouraging results, this study has many drawbacks. The study only looked at male football players under the age of 15, and the sample size was limited. Future studies might examine how MFR and SS affect injury prevention, the inclusion of female athletes, and their long-term impacts. Additionally, looking at MFR and SS together as a comprehensive flexibility intervention might yield more information about how to best train young athletes for flexibility.

CONCLUSION

The findings indicate that both techniques contribute to improved muscle flexibility; however, MFR demonstrated a slightly greater improvement in range of motion compared to SS. The enhanced flexibility observed with MFR may be attributed to its ability to release fascial restrictions, improve blood circulation, and reduce muscle tightness more effectively than static stretching alone.

Table 1: Age and Gender Distribution in Different Groups

VARIABLES	Group A	Group B
	Mean ± SD	**Mean ± SD**
Age	12.6 ± 1.29	12.86 ± 0.83
Gender (Male: Female)	7: 8	9: 6

In the present study, the mean age of participants was12.6 ± 1.29 years for group A and 12.86 ± 0.83 years for group B.

Table 2: Within-Group Comparison of VAS and the Silfverskiold Test in Group A

Variables Group A		MEAN	SD	T	p
VAS	Pre	6.80	0.69	29.73	<0.001
	Post	2.83	0.47		
SILFVERSKIOLD TEST	Pre	9.88	1.74	9.539	<0.001
	Post	11.53	1.55		

Significant improvements were seen in all outcome measures, that is, the pre-pain on VAS was 6.80 ± 0.69 and post-pain was 2.83 ± 0.47, Pre-Calf muscle flexibility on the Silfverskiold Test was 9.88 ± 1.74 and post-Calf muscle flexibility was 11.53 ± 1.55 for group A.

Table 3: Within-Group Comparison of VAS and the Silfverskiold Test IN Group B

Variables Group B		MEAN	SD	T	p
VAS	Pre	6.66	0.64	10.33	<0.001
	Post	5.38	0.71		
SILFVERSKIOLD TEST	Pre	8.9	1.54	8.93	<0.001
	Post	10.68	6.20		

All outcome measures showed significant improvements: group B's pre-pain score on the VAS was 6.66 + 0.64 and post-pain score was 5.38 + 0.71; group B's pre-calf muscle flexibility score on the Silfverskiold Test was 8.9 + 1.54 and post-calf muscular flexibility score was 10.68 + 6.20.

Table 4: Between-Groups Comparison of VAS and the Silverskiold Test

Variables	Group A (Mean ± SD)	Group B (Mean ± SD)	T	P
VAS	2.83 ± 0.47	5.38 ± 0.71	11.51	<0.001
SILFVERSKIOLD TEST	11.53 ± 1.55	11.4 ± 1.29	0.255	0.801

Both groups' between-group data were compared using the unpaired t-test. Group analyses for VAS revealed statistically significant differences, according to statistical data analyses. A non-significant impact was shown by the Silfverskiold test.

ABSTRACT

The field of surface modification is critical in enhancing the wear resistance, strength, and service life of engineering components. Traditional hardfacing methods involving arc welding, PTA, or laser cladding are characterized by high heat input and consequent occurrence of undesired thermal defects such as residual stress, dilution, or cracking. On the contrary, friction surfacing, which is a solid-state coating process derived from friction welding principles, can enable surface enhancements by controlled frictional heat and plastic deformation without melting of the substrate. This study focuses on optimization and modelling for the key process parameters in friction surfacing on aluminium substrates using silicon carbide reinforcement. The experiments were carried out on a 4 kW universal milling machine with a die-steel friction tool. The tool rotational speed and table traverse speed were varied systematically to understand their impact on surface hardness. It was seen that the most influential single parameter identified was rotational speed, contributing nearly 71% of total variation in hardness. For the obtained optimum condition of 3220 rpm and 30 mm/min of rotational speed and traverse speed, respectively, the maximum surface hardness was found at about 345 HV, nearly eight times that of the untreated substrate hardness. The regression model developed possesses very good predictive reliability with R^2 value of 0.96. From the findings, it can be concluded that friction surfacing with SiC reinforcement is an efficient and sustainable method for surface hardening of aluminium and also suitable for lightweight, high-performance engineering applications.

Keywords: Friction surfacing; Silicon carbide reinforcement; Process optimization; Aluminium surface hardening; Sustainable manufacturing; Taguchi–ANOVA modelling

INTRODUCTION

Friction Surfacing: A Sustainable Coating Technique

Friction surfacing was originally derived from friction welding and has since evolved into a reliable coating technique. The process allows solid-state bonding, leading to dense, defect-free coatings with strong adhesion and negligible dilution. Because it operates below melting temperature, the method avoids solidification defects common in fusion-based coatings. Its advantages include low energy consumption, environmental friendliness (no shielding gas or flux required), and compatibility with a wide range of substrate–tool combinations. In recent years, friction surfacing has been recognized as an Industry 4.0-aligned manufacturing process, particularly because of its suitability for automation, digital monitoring, and additive manufacturing integration. Its solid-state nature also makes it ideal for processing light metals such as aluminium, magnesium, and titanium, where controlling the heat input is critical.

Aluminium and the Need for Surface Enhancement

Aluminium and its alloys have been widely utilized in automotive, aerospace, marine, and structural applications owing to their high specific strength, low density, and corrosion resistance. However, low hardness (30-50 HV) and poor tribological properties of aluminium restrict its application in high-wear environments such as piston heads, connecting rods, and turbine blades. Traditional surface treatments include anodizing and plasma spraying, both of which pose temporary solutions and are often plagued with one or more problems relating to inadequate bonding, brittle coatings, or limited thermal stability. Surface improvement of aluminium using reinforced composite coatings has emerged as a viable approach. Addition of hard ceramic particles like silicon carbide (SiC), titanium carbide (TiC), or alumina (Al_2O_3) to the surface matrix can lead to significant improvement in wear resistance and microhardness owing to dispersion strengthening and grain refinement. Of these reinforcements, SiC is highly effective due to its very high hardness of ≈2500 HV, low density, and strong chemical inertness.

Motivation for Parameter Optimization

Although friction surfacing of aluminum with SiC has shown remarkable improvement in properties, the process parameters-rotational speed, traverse speed, and axial pressure-are critical for coating quality. Poor selection of the parameters may result in inadequate adhesion, uneven distribution of reinforcement, or surface defects. Systematic process optimization using statistical tools such as Taguchi design, ANOVA, and regression modelling is thereby essential to get reliable, reproducible, high-performance coatings. Such modelling not only reduces the number of experimental trials but also provides predictive capability for different operating conditions. The present paper deals with the optimization and mathematical modeling of some important friction surfacing parameters affecting the hardness of SiC-reinforced aluminum surfaces.

LITERATURE REVIEW

The research in the development of wear-resistant coatings is an active field for the last few decades. According to Berns and Fischer (1997), hardfacing materials are classified into three categories: iron-, cobalt-, and nickel-based alloys. They further added that wear resistance is strongly linked with microstructural control. Buchely *et al*. (2005) established that abrasive wear resistance is influenced directly by the microstructure of hardfacing alloys, while Chang *et al*. (2003) discussed that an increase in carbide fraction enhances the high-temperature wear properties. More recently, works published by Navas *et al*. (2006) and D'Oliveira *et al*. (2002) involved laser and PTA coatings, respectively, which, although very effective, have always suffered from high cost and complex process control. In contrast, friction surfacing has emerged as a cost-effective, eco-friendly, and scalable alternative for applying such coatings. Again, with regard to aluminium, Wang *et al*. (2005, 2008) explored Fe- and Ni-based overlays, respectively, and reported improvement in microhardness and wear resistance. However, such fusion-based coatings often led to excessive dilution and cracking. Accordingly, John Coronado *et al*. (2009) addressed that those coating processes which offer reduced dilution-for instance, solid-state coatings-provide superior mechanical performance. Though

friction surfacing research has gained momentum for ferrous substrates, limited studies targeted the aluminium system, especially with ceramic reinforcement. Hence, a systematic parametric study involving experimental validation, Taguchi optimization, and regression modelling for Al-SiC friction surfacing is relatively unexplored and thus forms the motivation for the present work.

EXPERIMENTAL PROCEDURE

Materials and Preparation

Commercially pure aluminium plates (99.5%) of size 140 mm × 100 mm × 10 mm were used as substrate materials. Silicon carbide powder of 320 mesh size (≈45 μm) was used as hard reinforcement. Friction tool was fabricated from die steel (AISI H13) of diameter 20 mm and machined to flat-end geometry suitable for surface deposition. Aluminium plates were cleaned using acetone followed by air drying to remove the residual oil, oxide, or dust that may interfere in bonding. Shallow grooves of depth ≈2 mm and 3 mm width were first milled on the surface to retain preplaced SiC powder.

Experimental Setup

The process was carried out on a 4 kW universal milling machine (Model: HPS 6336). The friction tool was mounted vertically on the spindle, and the aluminium work piece was clamped rigidly on the milling table. A controlled vertical pressure was applied, and the table was traversed at predetermined speeds beneath the rotating tool. The process ensured that heat was generated by frictional contact between the tool and substrate, resulting in a plasticized surface layer incorporating the SiC particles. The experimental setup is shown in Figure 1.

Process Parameters and Experimental Design

Two key process variables were selected based on prior experimentation:

Rotational Speed (A): 2000 rpm and 3220 rpm

Traverse Speed (B): 30 mm/min and 55 mm/min

The experiments followed a Taguchi L4 (2^2) orthogonal array design, reducing the number of tests while capturing the combined effects of the parameters. Table 1 shows the experimental plan and observations.

Characterization

Microhardness was measured using a Vickers microhardness tester (Wolpert-Wilson, Germany) with a load of 50 g and 10 s dwell time. Indentations were made at three locations on each sample surface, and the average was reported. Cross-sectional hardness profiles were also measured to assess the depth of reinforcement influence.

RESULTS AND DISCUSSION

Surface Hardness and General Observations

All samples exhibited a substantial increase in surface hardness compared to the untreated aluminium base (≈40 HV). The improvement was most pronounced at high rotational speed (3220 rpm) and low traverse speed (30 mm/min), yielding a hardness of 345 HV, about eight times higher than the base metal. This enhancement is attributed to the refined grain structure caused by dynamic recrystallization under frictional heat and the dispersion strengthening provided by uniformly embedded SiC particles. The frictional heat generated at higher rpm improves the plasticization of aluminium, enhancing interfacial diffusion and bonding. Conversely, higher traverse speed reduces exposure time, leading to insufficient bonding and marginally lower hardness.

Taguchi Signal-to-Noise Analysis

The larger-is-better criterion was used since higher hardness values were desirable. Table 2 shows the S/N ratio. The Delta value indicates that rotational speed has a much stronger impact on surface hardness than traverse speed. The optimal combination from S/N analysis is A_2B_1 (3220 rpm, 30 mm/min).

ANOVA for Significance Testing

The ANOVA results (Table 3) quantify each parameter's contribution to the overall variance. Table 3 shows the ANOVA results.

Interpretation

- Rotational speed accounts for 71.2% of the total variance, confirming its dominance.
- Traverse speed affects surface hardness moderately (17.1%).
- The residual error (11.7%) indicates minimal unmodelled variation.

The F-value for rotational speed exceeds the critical value (4.96 at 95% confidence), confirming its statistical significance.

Regression Modelling

A multiple regression equation was developed to predict hardness (HV) from process parameters:

HV = 175.25 + 0.056A - 1.15B

Where:

A = rotational speed (rpm),

B = traverse speed (mm/min).

Statistical Validation

- $R^2 = 0.96$
- Adjusted $R^2 = 0.94$
- Standard Error = ±8.2 HV

The high R^2 value confirms that 96% of the observed variation in hardness can be predicted by the model, indicating strong correlation and reliability.

Discussion of Mechanisms

The substantial hardness improvement can be attributed to several interacting phenomena:

Dynamic Recrystallization: The frictional heat and severe plastic deformation induce dynamic recrystallization, forming fine equiaxed grains that enhance hardness via the Hall–Petch mechanism.

Dispersion Strengthening: The SiC particles embedded in the aluminium matrix obstruct dislocation motion, increasing strength and resistance to indentation.

Work Hardening: The intense plastic deformation near the tool–substrate interface leads to dislocation pile-up and strain hardening.

Thermal Softening and Recovery: At higher traverse speeds, insufficient heat input prevents proper bonding, while excessive heat may lead to recovery, reducing hardness. Hence, a balanced parameter combination is critical.

Sustainability and Process Efficiency

From a sustainability standpoint, friction surfacing offers several advantages

- Low energy consumption compared to laser or arc processes.
- No consumable shielding gas or flux, reducing emissions.
- Minimal waste generation due to solid-state bonding.

- Reparability and reusability of worn components, aligning with circular manufacturing.

Therefore, optimizing friction surfacing parameters not only enhances product performance but also contributes to sustainable engineering practices under Industry 5.0 frameworks.

Comparison with Literature

Compared to previous works using fusion-based hardfacing (e.g., PTA, laser), the hardness obtained here (345 HV) is comparable or superior, considering the absence of melting and defects. D'Oliveira *et al*. (2002) reported hardness improvements of 3–4 times over base metal in Co-based overlays, while the present study achieves nearly 8× improvement with minimal energy input. This demonstrates that friction surfacing with SiC is a viable green alternative for lightweight alloys, offering both economic and environmental advantages.

CONCLUSIONS

Based on the experimental investigations and statistical analyses, the following conclusions are drawn:

1. Friction surfacing effectively improved the surface hardness of aluminium through the incorporation of SiC reinforcement, achieving hardness values up to 345 HV, nearly eight times higher than that of the untreated substrate.
2. Tool rotational speed was identified as the most influential parameter, contributing approximately 71% of the total hardness variation, while traverse speed contributed 17%.
3. The optimal process condition was determined as 3220 rpm rotational speed and 30 mm/min traverse speed, providing the best combination of heat input and deposition quality.
4. The regression model ($R^2 = 0.96$) demonstrated strong predictive capability and can be used for future process design.
5. The solid-state nature of the process ensures dense, defect-free coatings, making friction surfacing a sustainable and cost-effective method for extending the life of aluminium components.

Future work may focus on integrating microstructural analysis (SEM/EDS), wear testing, and finite element modelling to further validate and expand the predictive model developed here.

ACKNOWLEDGEMENTS

The authors express sincere gratitude to the Department of Mechanical Engineering, Brainware University, for providing laboratory facilities and technical support for this study. Special thanks to all research colleagues involved in data collection and testing.

ABSTRACT

Early detection of brain tumors is critical, as uncontrolled cellular proliferation can rapidly lead to fatal outcomes. This work explores the role of magnetic resonance imaging (MRI) in tumor detection and proposes a feature extraction and classification framework. Pre-processing is carried out using the Rudin–Osher–Fatemi (ROF) filter to enhance image quality. Discrete Wavelet Transform (DWT), Gabor Transform, and Grey Level Histogram Features (GLHF) are then applied for robust feature extraction. For classification, Support Vector Machine(SVM) and K-Nearest Neighbor (KNN) algorithms are employed to distinguish tumor-affected regions from normal brain structures. The study highlights an efficient approach to assist researchers and clinicians in improving diagnostic accuracy.

Keywords: Brain tumor, Magnetic Resonance IndexScan, ROF Filter, Discrete Wavelet Transform, Gabor Transform feature, Grey Level Histogram Feature,SVM Classifier, KNN Classifier.

INTRODUCTION

The human brain has multiple intricate neural systems, making it the most advanced organ in the body.Currently, radiological and clinical data serve as the foundation for diagnosis and treatment. The gold standard for evaluating patients with brain malignancies is magnetic resonance imaging, or MRI.About 9.6 million people died from brain tumors in 2018, making them the second leading cause of death worldwide. Brain tumors contribute to approximately ten percent of all deaths globally [1]. Medical experts have observed computer-aided diagnosis to be helpful [2].The inability of existing imaging techniques to recognize the margins of the disease within the normal-looking brain tissue is one of the several explanations why therapies may fail [3]. Therefore, in order enhance overall management, improved imaging techniques are essential when assessing brain tumors and the surrounding tissues [4].Improvements in imaging methods, such as magnetic resonance imaging (MRI), have become essential in detecting and diagnosing brain cancers, and early diagnosis is essential to improving treatment results.A non-invasive diagnostic imaging method for creating high-resolution pictures of the internal organs of the body is magnetic resonance imaging (MRI). An MR scan's image quality may suffer if there is noise present [5]. Strong magnetic fields, radio waves, and a computer are used to produce finely detailed images of the skeletal system, organs, and tissues. For many individuals, MRI is a safer option because it doesn't use ionizing radiation like CT or X-rays do.The diagnostic techniques used in brain MRI research are introduced in Section 1. The collection, processing, and application of picture data are covered in Section 2. The extraction of Wavelet, Gabor, GLHF features, and associated parameters from brain MRI data was demonstrated in Section 3. The KNN classifier observation and Decision tree are shown in Section 4. Results were discussed in Section 5. The study concludes its sixth section.

MATERIALS AND METHODS

Image Acquisition

Image acquisition is the first stage in every image processing operation. The main objective of image capture is to convert visual information from the physical world—like an optical image—into a digital format that computer technologies can process and evaluate. We used brain MRI pictures that were openly accessible on Kaggle for our investigation. The 400 brain MRI pictures that were collected were divided into two categories: those of healthy brains and those with cancerous growths. To start, MRI scans of the patient's brain are analysed to see if there is a tumor in the brain. 170 of the photographs in this sample are normal, whereas 230 include brain tumors. The first phases in our post are noise reduction and grayscale conversion. The second step allows us to modify the images in accordance with MATLAB's rules and guidelines.This paper illustrates how the collaborative approach can be used to improve the identification of brain tumors and how it can improve medical image processing [6].

Image Pre-processing

By removing or minimizing undesirable components like noise and superfluous colors, pre-processing attempts to raise the overall quality of photos. This makes it easier to concentrate on significant aspects, such as a tumor in an MRI scan, and enables a more precise and efficient examination of the image's key components. Pre-processing improves the image's clarity by cleaning it up, making further processing or analysis more dependable and effective. Pre-processing techniques like noise reduction are
essential if the original image quality is low in order to guarantee that the finished product can be used for additional assessment or decision-making. The figure 1 represents the tumor image [22]

ROFFilter

The foundation of image recovery methods like denoising and deblurring, which are essential image processing operations, is regularization. It is difficult yet highly appealing to maintain image edges and features during the regularization process. In the repair of edge-preserving images, the ROF model has proven to be highly efficient. This has led to a lot of interest in it, and it has been expanded to include high-order and vectorial frameworks for colour

image restoration. The theory behind total variation (TV) regularization, which is frequently employed for noise reduction in digital image and signal processing, is that signals with excessive and possibly manufactured details show a significant integral of the signal's absolute gradient or high total variance. This technique efficiently eliminates extraneous information while maintaining crucial features like edges by lowering the overall variation while guaranteeing the signal stays closely to its original form. In 1992, Rudin et al. first proposed this idea [7]. Previous image restoration techniques used least squares, which had the disadvantage of either creating undesired oscillations close to edges, like the well-known ringing phenomena, or blurring edges. Nonetheless, two of the most important aspects of digital photos are their edges and textures.In order to address this problem and enable noise reduction while maintaining edges and fine details, a great deal of study has gone into creating improved models. One of the most well-known and actively researched topics in computer vision and mathematical image processing is variational models. They have demonstrated exceptional efficacy in a variety of picture restoration tasks among the many modified versions. One well-known illustration of a variational model is the ROF model [8]. In addition to noise reduction, variational modelling can be used for deblurring, blind deconvolution techniques, and inpainting. These models minimize functionals using nonlinear PDEs to solve restoration problems as efficiently as possible. In their groundbreaking PDE-based edge-preserving denoising technique, Rudin, Osher, and Fatemi (ROF) presented complete variation-based image restoration. Edges are preserved while noise and fine-scale features are successfully eliminated by the ROF model. It is a straightforward yet effective technique for image restoration because, being a convex variational system, it dissuades oscillations while permitting discontinuity [9]. A visual reduced noise approach was proposed by E. Fatemi, S.J. Osher, and L. Rudin. They recreate the clean image u using an actual intensity function f and the assumption that f = u + η, where η is additive noise, occurs. They suggest reducing the following attributes:

$J(u) = \int_{\Omega}|\nabla u| + \lambda \int_{\Omega}(f-u)^2$

pertaining to a specific modifying variable $\lambda > 0$. When u has bounded variation, which means that u ∈ BV(Ω), the expression $\int_{\Omega}|\nabla u|$ represents the entire variation of u. The above equation is hence known as the Rudin–Osher–Fatemi algorithm (ROF). As a remedy for the decreasing issue, Rudin, Osher, and Fatemi suggested forecasting the denoised image u.

$$\underset{u\in BV(\Omega)}{argmin}\|u\|_{TV(\Omega)} + \frac{\lambda}{2}\int_{\Omega}(f(x)-u(x))^2\,dx\,,$$

A value that is greater than zero is used when λ is used. The Rudin-Osher-Fatemi, or ROF, dilemma is the name given to this one. Denoising entails resolving an infinite-dimensional minimization problem in which all bounded variation (BV) images make up the target field. If an expression is compatible and has a Radon measure Du, then it is in BV (Ω).

$$\int_{\Omega} u(x)div\vec{g}(x)\,dx = -\int_{\Omega}\left(\vec{g}, Du(x)\right) \quad for\ all\ \vec{g} \in C_c^1(\Omega, R^2)^2$$

A metric called Du is used to express the distributional gradient of u. Smooth u may be found using the formula Du(x) = ∇u(x) dx. For u, the total variation (TV) semi norm is

$$\|u\|_{TV(\Omega)} := \int_{\Omega}|Du| := sup\left\{\int_{\Omega} u\ div\ \vec{g}\,dx :\ \vec{g} \in C_c^1(\Omega, R^2)^2, \sqrt{g_1^2+g_2^2} \le 1\right\}$$

TV equals an integral of the value of a gradient if u is smooth.

$$\|u\|_{TV(\Omega)} = \int_{\Omega}|\nabla u|\,dx$$

Despite it allows for delays, the TV part of the decreasing encourages shifts in the outcome. The following component supports an approach that resembles the footage that has been seen f. The decreased algorithm uses the above combination to produce a denoised image. If f∈L^2, there is a unique, permanent minimizer of the ROF problem in L^2that is unaffected by modifications to f [10].

There are benefits to this noise reduction technique over simpler approaches like median filtering or linear smoothing, which improve the look of photos but go a different path by relaxing along borders. The reliability of

predictions is improved by the ROF model filter. The study's conclusions are put into practice to produce noise-free images that may be used to extract features.

FEATURE EXTRACTION

Discrete Wavelet Transform

An excellent instrument for image processing, the Discrete Wavelet Transform (DWT) provides improved evaluation of image localized in both the duration and frequencies dimensions. Originating from the French word "omelette," which denotes a little wave, the name "wavelet" was first used by Grossman and Morlett in the early 1980s. In many imaging applications, a wavelet is a confined oscillatory function. Discrete wavelets, which were first used in seismology for time estimate in seismic spectroscopy, produced results for unpredictable occurrences that were stable but less accurate. When the Fourier transform didn't work as expected, they were used in seismology. The investigators applied discrete wavelet transform in a variety of fields outside seismology, including communications, signal and image processing, quantum mechanics, and mathematics applications [11]. A signal is divided into two distinct phases, such as rough estimation and detailed data in a discrete wavelet transform. DWT has two sets of functions. Low pass filters handle scaling functions, while high pass filters handle wavelet functions. Through the use of successive high pass and low pass filters, a signal in the temporal domain is broken down into distinct frequency bands. After passing the initial signal with a half-band high pass filter, a low pass filter is applied [12].The image is broken down into three places of interest, one zoom, and sub-images or sub-ranges by DWT. These are the groups: LL, LH, HL, and HH.

LL (Approximation sub-band): offers a rough representation of the original image while maintaining its important features and energy thanks to its low noise levels in vertical as well as horizontal dimensions.

LH (Horizontal detail sub-band): highlights vertical boundaries and features by capturing great vertical and low horizontal frequency.

HL (Vertical detail sub-band): emphasizes the horizontal lines and features with its high horizontal and low vertical frequencies.

HH (Diagonal detail sub-band): enhances fragile details and diagonally borders by including high frequencies in every direction [13].

The inverted part of the modification matrix relates to the opposite of the change expressed in a matrix of numbers, and discrete wavelet transforms are symmetrical and reversible. The wavelet function in mathematics always has an integral of zero throughout the interval (-∞, ∞). If we assume that x is the mother wavelet or fundamental wavelet, then the subsequent formulas describe the wavelet foundation, also referred to as the orthonormal standard.

$$\Psi_{(j,k)}(x) = 2\frac{j}{2}\,\Psi(2^j x - k)$$

and the following is the scaling function:

$$\Phi_{(j,k)}(x) = 2\frac{j}{2}\,\Phi\,(2^j x - k)$$

where j and k are integers that reflect the wavelet base scaling and dilation, and Ψ is the wavelet function. The width scale index is represented by the factor "j," while the position is represented by the factor "k."[14]. The wavelet equation can be expressed in terms of coefficients as follows:

$$\Psi(x) = \sum_{k}^{n-1} g_k\left(\sqrt{2\Phi(2x-k)}\,\right)$$

where the high pass wavelet coefficients $g_0$and g_1: indicate the time series evolving at a particular resolution.

Gabor Transform Feature

Dennis Gabor created the Gabor transform as an enhancement to the Fourier transform. It overcomes the Fourier transform's drawback of just providing a frequency dimension of a signal not revealing the times at which those wavelengths occur. The Gabor transform creates a graph of frequencies that shows energy over time by fusing a Gaussian distribution function with the Fourier transform.

For identifying the interval at which different rates occur, the Gaussian distribution function is used in this transform as a kernel that travels along one-dimensional signals and calculates the outcome of the Fourier transform and the

Gaussian function throughout its range of values [15].The Gabor transform can be used to examine the local characteristics of the signal at various places, which sets it apart from the Fourier transform's whole time-domain analysis method. It can exhibit outstanding localization in both the spatial and frequency domains and is the function to approach the bottom bound where the time domain cannot have a correct detection.

As a result, it has been widely used in domains like picture recognition and analysis. The Gabor function may extract pertinent characteristics in many frequency domain scales and orientations because it is a windowed Fourier transform. In general, the Fourier transform of the two-dimensional Gabor function $g(x,y)$can be expressed as

$$g(x,y) = \frac{k^2}{\sigma^2} exp\left(-\frac{k^2(x^2+y^2)}{2\sigma^2}\right).\left[exp\left(ik.\begin{pmatrix}x\\y\end{pmatrix}\right) - exp\left(-\frac{\sigma^2}{2}\right)\right]$$

$$G(u,v) = exp\left[-\frac{1}{2}\left(\frac{(u-w)^2}{\sigma_u^2} + \frac{v^2}{\sigma_v^2}\right)\right]$$

Applying $g(x,y)$as the mother wavelet, the Gabor wavelet transform can be obtained by expanding and rotating the mother wavelet. $\sigma_u = \frac{1}{2\pi\sigma_x}$, $\sigma_v = \frac{1}{2\pi\sigma_y}$, The Gabor function is one of these; it forms a complete non-orthogonal basis function and can be used to describe the local frequency range with the signal expanded from the basis. The Gabor wavelet is an identical functioning.

$g_{mn}(x,y) = a^{-m}G(x',y')$ $a > 1, n, m \in Z$

$x' = a^{-m}(xcos\theta + ysin\theta), y' = a^{-m}(-xsin\theta + ycos\theta)$

The Gabor function is widely [16]employed in texture recognition and has achieved great success. In this case, $\theta = \frac{n}{k}\pi$, where k is the number of directions and $a^{-m}$is the scaling factor.

Grey Level Histogram Feature

An image's histogram can be used to generate statistical features known as Gray-Level Histogram Features (GLHF). The frequency distribution of pixel intensity values is represented as a histogram, which makes GLHF an effective tool for examining changes in texture, contrast, and intensity in photos. This technique is frequently applied in computer vision, medical imaging, and pattern identification [17].The mathematical equation that translates every brightness grade (from 0 to 255 in an 8-bit grayscale image) to the amount of pixels with the respective intensity is known as the gray-level histogram. The definition of the histogram is:

$$H(i) = \sum_{x,y} \delta(I(x,y) - i)$$

where,

- $H(i)$ represents intensity i histogram value
- $I(x,y)$ is the pixel's intensity at that specific place (x,y)
- $\delta(\cdot)$consists of the Kronecker delta function, which is 0 otherwise and 1 when the condition is met.

CLASSIFICATION

- ***Support Vector Machine***
- A potent supervised machine learning method, the Support Vector Machine (SVM) is typically used for tasks involving regression and classification. It works by creating an ideal separation hyperplane that maximizes the distance between data points from various classifications. The classifier's capacity to efficiently generalize to novel, unseen data is enhanced by this ideal margin. SVM's ability to effectively handle both linearly and non-linearly separable data using kernel functions like linear, polynomial, radial basis function (RBF), and sigmoid is one of its main advantages.
- SVM finds a selection of important data points during training, referred to as support vectors, which are crucial in establishing the decision boundary[18]. The model is resistant to overfitting and computationally economical because to the usage of these support vectors, particularly in high-dimensional feature spaces. In comparison to a number of other classification methods, SVM also shows good accuracy and lower prediction durations. By displaying correctly and erroneously categorized samples during the training phase, visualization tools like scatter plots can be used to assess an SVM classifier's effectiveness.

- The classification results are also quantitatively summarized by the confusion matrix, which shows true positives, false positives, true negatives, and false negatives. This assessment procedure aids in determining the classifier's overall efficacy and makes it easier to compare it to other machine learning models.

K- Nearest Neighbors (KNN)

One of the most straightforward and understandable learning algorithms is k-Nearest Neighbor (KNN). KNN can also be regarded as an excellent methodology to be carried out and distribution [19]. The supervised machine learning method known as k-Nearest Neighbours (k-NN) is used for classification and regression applications. The method generates suggestions based on the extent to which data items match the characteristics**.** The overriding choice of classifications determines the K-nearest neighbor classification. Classification is achieved by identifying the request instance's nearest neighbors and [20] using those neighbors to determine the search class. Classifying an example using the overwhelming categorization of its K nearest neighbors in the space of characteristics is a passively learned technique. The chosen neighbors are labeled training samples. Algorithm Principle: The features of an unlabeled sampling are retrieved for comparison with a training dataset. The most prevalent categorization across the K closest-matching examples (nearest neighbors) [21] is allocated to the sample. The simplest components needed to train a KNN classifier are the feature vectors and the tags of the training images; the amount of processing time required will depend on how many training instances (features) are chosen. The categorization method involves selecting the neighbor that is closest to the predetermined number of k. A typical method for classifying an object according to its k-nearest neighbor is to utilize Euclidean distance. In order to prevent ambiguity, k must be an odd number. As seen in the Euclidean distance calculation, the nearest vector can be found using

$$d(x,y) = \sqrt{\sum_{i=1}^{m}(x_i - y_i)^2}$$

Where,

$d(x,y)$ – The closest Vector

x , y – training and testing

i – the number of feature used.

RESULTS AND DISCUSSION

Among the main considerations are Accuracy, False Alarm, Performance Index, Specificity, Sensitivity, and MSE taken into consideration when categorizing MRI scans of brain tumors [22]. A table commonly used to demonstrate the performance of a classification model, sometimes referred to as a "classifier," when performed to an assembly of information samples where the real values have been established is called a confusion matrix. It enables the evaluation of a procedure's performance. The following is the typical format:

True Positive (TP):The model correctly predicted that the positive class would be present.

True Negative (TN):The algorithm accurately predicted the negative class.

False Positive (FP):A "Type I error" occurs when the model incorrectly predicts the positive class.

False Negative (FN):A "Type II error" occurs when the algorithm incorrectly predicts the negative class.

The following are the formulas used to calculate the accuracy, sensitivity, and specificity parameters:

Table 1 Comparative analysis of classifier performance with accuracy

$$Sensitivity = \frac{TP}{TP + FN} \times 100$$

$$Specificity = \frac{TN}{TN + FP} \times 100$$

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \times 100$$

$$Precision = \frac{TP}{TP + FP} \times 100$$

$$F1\ Score = 2 \times \frac{Specificity \times Sensitivity}{Specificity + Sensitivity} \times 100$$

$$JaccardMatric = \frac{TP}{TP + FN + FP} \times 100$$

$$BalancedClassifierRate = \frac{Specificity + Sensitivity}{2}$$

$$MCC = \frac{(TP - TN) - (FP - FN)}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}}$$

Table 1 shows the performance analysis of the classifiers. Here, we use KNN and SVM to compute and show the performance level of several feature extraction methods from brain tumor images, such as Wavelet, Gabor, and GLHF. Table 1 shows that the Wavelet transform with KNN feature achieved 90.75% accuracy for brain tumor classification, while the Gabor and GLHF feature extraction techniques achieved lower frequency accuracy, respectively.

CONCLUSION

The effectiveness of Wavelet, Gabor, and GLHF feature extraction techniques is analyzed using MATLAB. To reduce image noise, a ROF filter is used. Following normalization, normal and abnormal MRI scans are identified using the Wavelet feature extraction method's average outputs. Three feature extraction methods and two classifier models are used to identify abnormalities in brain tumors. When combined with the Wavelet approach, the KNN classifier has the highest accuracy among them, attaining a median reliability of 90%. This illustrates how the suggested approach may be used to quickly and precisely identify abnormalities in the brain across a variety of MRI datasets.

ABSTRACT

Phytic acid, the primary storage form of phosphorus in cereals and legumes, reduces mineral bioavailability and contributes to environmental phosphorus loading due to its indigestibility. Phytase enzymes play a crucial role in hydrolyzing phytic acid, thereby enhancing phosphorus availability and improving nutritional and ecological outcomes. In this study, phytase-producing bacteria were isolated from the rhizosphere soil of *Oryza sativa*. Preliminary screening on wheat bran extracts medium revealed clear hydrolysis zones, confirming phytase activity. The most potent isolate was identified as *Bacillus megaterium* through 16S rRNA gene sequencing. Optimization experiments indicated that phytase production was maximal at 1% glucose as the carbon source, 1% peptone as the nitrogen source, pH 7.0, and 35 °C incubation. Partial purification of the enzyme yielded significant activity (4.705 IU/ml), as confirmed by plate and spectrophotometric assays. The findings highlight *Bacillus megaterium* as a promising candidate for phytase production, with potential applications in sustainable agriculture, biofertilizer development, and feed and food industries.

Keywords: Phytase, *Bacillus megaterium*, Rhizosphere soil, *Oryza sativa*, Phytic acid, Enzyme optimization, Biofertilizer

INTRODUCTION

Phytic acid (myo-inositol hexakisphosphate) is a key anti-nutritional factor found predominantly in cereals and legumes, where it acts as the principal storage form of phosphorus (Raboy, 2001; Habtamu Fekadu, 2014). Its salt form, phytate, strongly chelates essential minerals such as zinc, iron, calcium, and magnesium, rendering them unavailable for absorption in humans and monogastric animals (McCance and Widdowson, 1942; Brune *et al*., 1992). Additionally, phytate forms indigestible complexes with proteins and carbohydrates (O'Dell and de Boland, 1976; Rickard and Thompson, 1997). Due to low endogenous phytase activity, humans and animals are unable to metabolize phytate effectively, leading to nutrient deficiencies (Wodzinski and Ullah, 1996; Lopez *et al*., 2002). Furthermore, undigested phytate contributes to environmental phosphorus loading, resulting in eutrophication and associated ecological damage (Cheryan, 1980). Phytate accounts for 60–80% of total phosphorus in plant seeds (Loewus, 2002; Gupta *et al*., 2025). Its persistence in food and soil systems necessitates enzymatic degradation to improve both nutritional and environmental outcomes. Phytase enzymes, first identified by Suzuki *et al*. (1907) from rice bran, hydrolyze phytate to release inorganic phosphate and lower inositol phosphates, enhancing phosphorus bioavailability (Wodzinski and Ullah, 1996; Wyss *et al*., 1998). These enzymes are widely distributed in plants, animals, fungi, and bacteria, with microbial phytases being the most industrially relevant due to their broad substrate specificity and functional stability under acidic conditions (Yao *et al*., 2011; Kumar *et al*., 2010; Baruah *et al*., 2007). Acidic phytases dominate among microbial sources, though certain *Bacillus* strains exhibit alkaline activity (Selle *et al*., 2007). In plants, root-secreted phytase activity is often insufficient for utilizing soil phytates, making rhizosphericmicrobes' key contributors to phosphorus mobilization (Kashirskaya *et al*., 2020). Microorganisms such as *Bacillus amyloliquefaciens*, *Pseudomonas* spp., and *Sporotrichum thermophile* secrete phytases that enhance phosphorus availability and plant growth, especially in phosphorus-limited environments (Idriss *et al*., 2002; Richardson *et al*., 2001b; Singh and Satyanarayana, 2010). Phytase application extends beyond agriculture into animal nutrition, where it addresses the inefficiency of phytate utilization in monogastric species by reducing the need for inorganic phosphate supplementation (Schindler, 1977; Burkholder *et al*., 1998). Environmental concerns about phosphorus-rich animal waste led to regulatory mandates and the development of commercial phytase products (Kerr *et al*., 2010). A notable breakthrough was achieved by International Minerals and Chemicals (IMC), which screened over 2,000 microbes and identified *Aspergillus niger* as a potent phytase producer, leading to the first commercial enzyme formulations in the 1990s (Wodzinski *et al*., 1996; Irving *et al*., 1972). Supplementation with 500–1,000 U/kg of phytase has proven effective in improving phosphorus utilization and mitigating environmental impact (Kerr *et al*., 2010). The present study aimed to isolate and screen phytase-producing bacteria from the rhizosphere soil of *Oryza sativa*, followed by strain identification, optimization of culture conditions, enzyme extraction and partial purification, and preliminary evaluation of its potential applications.

MATERIALS AND METHODOLOGY

Collection of Rhizosphere Soil Samples

Rhizosphere soil samples were collected from *Oryza sativa* plants in Kanchipuram, Tamil Nadu. Before collection, the soil was dug to a depth of 5–50 cm, and plants were carefully uprooted to obtain the soil adhering to the roots. The samples were immediately placed in an icebox to preserve microbial activity and transported to the laboratory for further analysis (Mussa *et al*., 2023).

Preparation of Phytase-Specific Medium (Wheat Bran Medium)

Phytic acid was extracted from wheat bran for the preparation of wheat bran medium used in screening phytase-producing bacteria. The extraction followed the method described by Canan *et al*. (2011). Briefly, 25 g of wheat bran was mixed with 250 mL of 1 N HCl and stirred for one hour at room temperature. The pH of the mixture was adjusted to 6.2 using 4.0 N NaOH to precipitate wheat bran protein. The sample was centrifuged at 3000 rpm for 10 min, and the supernatant was collected (Wu, 1993).

The pH of the supernatant was then adjusted to 8.0 using 1.5 M Na_2CO_3 and left at room temperature for 12 h. After centrifugation under the same conditions, the supernatant was discarded, and the pellet was resuspended in 1.0 N HCl. To remove impurities and denatured proteins, 10 mL of formaldehyde and 0.5 g of celite were added. The mixture was shaken for 2 h and kept undisturbed at room temperature for 20 h. The suspension was filtered through Whatman filter paper No. 3, and the filtrate was adjusted to pH 7.0 with 1.5 M Na_2CO_3. The wheat bran extract medium was prepared according to Powar and Jagannathan (1982). To 100 mL of phytic acid extract, 0.5% peptone, 1% NaCl, 0.5% yeast extract, and 2% agar were added. The mixture was boiled until clear, adjusted to pH 7.0, and sterilized at 121 °C for 15 min at 15 psi.

Isolation and Screening of Phytase-Producing Bacteria

After sterilization, the wheat bran medium was poured into sterile Petri plates and allowed to solidify. Serial dilutions of the rhizosphere soil samples were prepared, and 0.1 mL aliquots of each dilution were spread onto the agar plates using a sterile bent glass rod. Plates were incubated at 37 °C for 48 h. Colonies exhibiting phytase activity were identified by clear zones around them, indicating hydrolysis of phytic acid (Mussa *et al*., 2023; Powar and Jagannathan, 1982). Selected isolates were further screened on wheat bran agar plates. The formation of a halo zone confirmed phytase production (Chunshan *et al*., 2001).

Identification of the Phytase-Producing Bacteria

The potent phytase-producing isolate was characterized by Gram's staining and identified using 16S rRNA gene sequencing (Avinash *et al*., 2013). DNA was extracted by the chloroform/isoamyl alcohol method. The sample was treated with lysis buffer containing proteinase K, followed by ethanol precipitation and elution into nuclease-free water. DNA quality and quantity were assessed using Nanodrop and agarose gel electrophoresis. Amplification of the 16S rRNA gene was performed using primers 27F and 1492R. PCR products (~1200 bp) were purified with the Nucleospin Gel and PCR Clean-up Kit and sequenced using the Sanger method with both forward and reverse primers. The raw data were assembled using Proview Sequencing software. Contigs were generated using BioEdit software and analyzed through BLAST for similarity with known bacterial sequences.

Optimization of Phytase Production Medium

Optimization of phytase production was carried out following Sreedevi and Reddy (2012) using the selected isolate from *O. sativa* rhizosphere soil.

Effect of Carbon Source: Wheat bran medium was supplemented with 1% (w/w) of glucose, sucrose, galactose, starch, or lactose. The isolate was inoculated and incubated at 37 °C for 48 h. After fermentation, broths were centrifuged, and phytase activity was measured.

Effect of Nitrogen Source: Wheat bran medium was supplemented with 1% (w/w) ammonium sulfate, ammonium nitrate, peptone, or sodium nitrate. Fermentation and enzyme activity estimation were performed as above.

Effect of Temperature: Cultures were incubated at 25, 30, 35, and 40 °C for 48 h, and phytase activity was assessed (Mussa *et al*., 2023).

Effect of pH: The medium was adjusted to pH 5, 6, 7, and 8 before inoculation. Cultures were incubated for 48 h at 37 °C, and phytase activity was determined.

Production and Extraction of Phytase Enzyme

Phytase production was carried out following Sreedevi and Reddy (2013) and Mussa *et al*. (2023) using wheat bran medium optimized with 1% glucose, 1% peptone, and pH 7.0. Cultures were incubated in a shaking incubator at 35 °C for 48 h. The broth was centrifuged at 6000 rpm for 30 min at room temperature, and the supernatant was collected as the crude enzyme extract.

Partial Purification of Phytase Enzyme

Partial purification was performed by ammonium sulfate precipitation and dialysis (Patki *et al*., 2015; Sreedevi and Reddy, 2013). Ammonium sulfate was added to crude extract (80 mL) to achieve 60–80% saturation. The mixture was incubated at 4 °C for 24 h, centrifuged at 9000 rpm for 30 min, and the pellet was dissolved in 0.2 M phosphate buffer (pH 7.4). The solution was desalted by dialysis against phosphate buffer (pH 7.0) at 4 °C for 24 h, with buffer replacement every 5 h.

Phytase Enzyme Assay

Phytase activity was by chemical assay methods.

The enzyme was collected from the dialysis bag, and its concentration was estimated in 1 ml of the pellet. Enzyme activity was measured by using the Ferroussulphate molybdenum blue method. Different concentration of the working standard solution of inorganic phosphate was prepared, (5mM, 10mM, 15mM, 20mM, 25mM) and used as a standard. 0.2 ml of theobtained supernatant was mixed with 0.16 ml of substrate solution containing 2 mM sodium phytate, 2 mM calcium chloride, and 0.1 M Tris-HCl buffer. The reaction mixture was incubated at 37°C for 30 minutes. To terminate the reaction, 2 ml of 5% trichloroacetic acid was added, followed by the addition of 2 ml of freshly prepared colouring reagent. The colouring reagent was prepared by mixing four volumes of 1.5% ammonium molybdate in 5.5% sulfuric acid with one volume of 2.7% ferrous sulphate solution. The absorbance of the reaction mixture was then measured at 700 nm to determine phytase activity. The amount of inorganic phosphorus released was determined using different concentrations of di-potassium hydrogen phosphate (K2HPO4) as a standard. The micromoles of inorganic phosphate released in a minute were used to calculate the phytase activity (IU/ml of CFS) as describedby Anastasio *et al*., (2010) and Mussa *et al*.,(2023).

EnzymeActivity(µmol/minml)or(IU/ml): IU/ml

$$\frac{concentration\ of\ product\ of\ reaction\ (\mu mol) \times Total\ reaction\ volume\ (ml)}{Reaction\ time\ (min) \times Enzyme\ volume(ml)}$$

RESULTS

The clear zone of hydrolysis produced by Rhizosphere bacterial isolates were observed on wheat bran medium. The larger clear zone with a diameter of 10 mm was selected. Isolation and screening of Phytase producing bacteria on Wheat bran extract medium from Rhizosphere soil of *Oryza sativa* (fig1). Characterization of Phytase producing bacteria (Table1). By16srRNAGenesequencing, the phytase-producing bacteria was identified as *Bacillus megaterium.* Effectsof Carbon on PhytaseProduction (Table2). Effect of carbon source on Phytase production (Graph 1). Effects of nitrogen on phytase production (Table 3). Effects of different Nitrogen sources on phytase production (Graph 2). Effects of Temperature on phytase production (Table 4). Effects of Temperature on phytase production (Graph 3). Effect of pH on phytase production (Table 5). Effect of pH on phytase production (Graph 4). Estimation of phytase enzyme with optimized conditions (Table 6). The phytase enzyme activity was determined to be 4.705IU/ml in 0.2ml of the partially purified enzyme.

DISCUSSION

Research on the use of phytase in food processing and manufacturing for human consumption holds great potential, particularly in enhancing the nutritional value of plant-based foods and improving food processing techniques. During food processing, the dephosphorylation of phytate results in the formation of partially phosphorylated myo-inositol phosphate esters, which exhibit reduced interference with the intestinal absorption of dietary minerals (Konietzny *et al*., 2003). In the present study, phytase-producing bacteria were successfully isolated from the rhizosphere soil of *Oryza sativa* using wheat bran extract medium. The formation of clear zones around bacterial colonies indicated phytase activity, with halo zones ranging from 8 to 10 mm. These results are consistent with earlier findings. Aziz *et al*. (2015) reported phytase-producing bacteria isolated from soil, with hydrolytic clear zones >6 mm, while Sharma *et al*. (2013) also identified diverse phytase-producing bacteria from environmental soil samples.

Molecular characterization confirmed the isolate as *Bacillus megaterium* through 16S rRNA gene sequencing. Similar approaches have been adopted by Mussa *et al*. (2023), who isolated phytase-producing bacteria from soil, poultry, and cattle shed samples and identified them using 16S rRNA sequencing. The nutritional and environmental parameters for optimum phytase production by *Bacillus megaterium* were determined. Glucose was identified as the most effective carbon source, yielding 2.245 IU/ml (Table 2; Graph 1), while peptone served as the best nitrogen source with 3.371 IU/ml activity (Table 3; Graph 2). The enzyme exhibited maximum activity at 35 °C (3.466 IU/ml) (Table 4; Graph 3) and at neutral pH 7 (3.953 IU/ml) (Table 5; Graph 4). These results are comparable with those reported in the literature. Basel *et al*. (2024) observed enhanced phytase production with glucose (148 IU/ml) and peptone (162.45 IU/ml) at 35 °C and pH 6.5. Kumar *et al*. (2013) further confirmed optimum phytase production by *B. megaterium* at 37 °C, while Sreedevi and Reddy (2012) demonstrated that glucose enhanced phytase activity in *Bacillus* spp. The present finding that 35 °C is optimum agrees with earlier studies (Sunitha *et al*., 1999; Lan *et al*., 2002), which reported that *Bacillus* species produce phytase effectively at mesophilic temperatures ranging from 30–40 °C. Similarly, the optimum pH observed in this study (pH 7) aligns with earlier findings. Sunitha *et al*. (1999) reported that *Bacillus subtilis* US417 exhibited stable phytase activity within a pH range of 6–7.5, with peak production at pH 6.5. The identification of peptone as the best nitrogen source in this study contrasts with previous reports. For instance, Kumar *et al*. (2013) and Sreedevi (2012) identified ammonium sulfate and ammonium nitrate, respectively, as the most suitable nitrogen sources for phytase production. This suggests strain-specific variability in nitrogen utilization for phytase biosynthesis. Furthermore, wheat bran extract was found to be an effective fermentation substrate in this study. This is consistent with the findings of Sreedevi (2012), who reported wheat bran as an excellent substrate for phytase production due to its phytate-rich composition. Enzyme activity analysis revealed that *Bacillus megaterium* exhibited a phytase activity of 162.03 mM/ml, significantly higher than values reported in earlier studies. Devadharshini and Soundhari (2024) recorded only 13 mM/ml in submerged fermentation, whereas Mussa *et al*. (2023) observed a much lower activity of 1.51 mM/ml. The partially purified enzyme in this study demonstrated an activity of 4.705 IU/ml in 0.2 ml. These results surpass earlier findings; Gulati *et al*. (2007) reported a maximum titer of 2.96 IU/ml for *Bacillus laevolacticus*, while Rao *et al*. (2008) achieved 4.29 IU/ml with *Escherichia coli* expressing a phytase gene from *Bacillus* sp. under optimized conditions. Overall, the present study highlights the potential of *Bacillus megaterium* as a robust phytase producer. The strain exhibited strong phytase activity under optimized conditions using wheat bran extract as a cost-effective substrate, thereby offering potential applications in food processing and nutrition enhancement. These findings not only align with previous reports but also provide improved values, indicating the significance of *Bacillus megaterium* for future applications in bioprocessing and industrial enzyme production.

CONCLUSION

This study demonstrates that *Bacillus megaterium* isolated from rhizosphere soil is a potent phytase producer with high enzyme activity under optimized conditions. Its ability to utilize wheat bran extract as a low-cost substrate and its superior phytase yield highlight its potential for industrial applications in food processing, particularly for enhancing mineral bioavailability and nutritional quality of plant-based diets.

ABSTRACT

In game theory, two-person zero-sum games represent strategic interactions in which one player's gain is exactly the other player's loss. This paper presents a comprehensive overview of optimal strategies in such games, focusing on mixed strategies, payoff matrices, and saddle points. We demonstrate an example using a 2×3 payoff matrix and solve it using the linear programming approach, ultimately deriving the game's value and the optimal strategies for each player. One player's gain is exactly the other player's loss, and optimal strategies ensure each player minimizes their maximum possible loss.

Keywords: Two-person zero-sum game, Optimal strategy, Game theory, Minimax strategy, Saddle point, Payoff matrix, Mixed strategy.

INTRODUCTION

The study of two-person zero-sum games lies at the very heart of classical game theory and continues to serve as an intellectual cornerstone for more complex strategic models[1]. In such games, the interests of two rational players are perfectly opposed: one player's gain is the other's loss, and thus the sum of their outcomes is always zero. This elegant simplicity not only makes zero-sum games mathematically tractable but also deeply insightful, especially when modeling adversarial interactions such as military conflicts, competitive markets, or strategic sports scenarios[2]. What makes the two-person zero-sum game particularly intriguing is its capacity to reveal how rational agents behave under pure conflict, without room for cooperation or mutual benefit. The game's structure compels each player to strategize not only based on their own preferences but also in full anticipation of the opponent's

countermoves[3]. This interdependence of decisions invites a careful analysis of optimal strategies, particularly when no pure strategy solution (or saddle point) exists. The pioneering work of John von Neumann and Oskar Morgenstern in the mid-20th century formalized this setting in mathematical terms. Von Neumann's Minimax Theorem, arguably the most famous result in game theory, states that for every finite two-person zero-sum game, there exists a value VVV and a pair of mixed strategies such that one player can guarantee at least VVV, and the other can hold the loss to at most VVV[4]. This equilibrium is not just a theoretical abstraction—it forms the rational solution concept in adversarial games and serves as the foundation for optimization techniques across disciplines. In practical terms, the optimal strategy in a two-person zero-sum game may involve pure strategies—a deterministic choice—or mixed strategies, where the player randomizes among available options to keep the opponent uncertain and unexploitable. The presence or absence of a saddle point in the game's payoff matrix determines which type of strategy is optimal. When a saddle point exists, the optimal strategy is straightforward: play the corresponding pure strategy[5]. However, when it does not exist, as is common in asymmetric games, players must resort to mixed strategies, often requiring the application of linear programming, graphical methods, or iterative algorithms to compute. The goal of this paper is to explore the determination of optimal strategies in two-person zero-sum games through both analytical and numerical techniques. Using illustrative examples, we demonstrate how to derive the value of the game and the players' optimal strategies. By understanding the interplay between game structure, saddle points, and strategy formulation, we not only gain insight into specific games but also into the general nature of strategic conflict.

MATERIALS AND METHODS

A rigorous understanding of two-person zero-sum games necessitates clarity in the foundational concepts that underpin the theory. These core definitions not only provide the structure for modeling adversarial decision-making but also form the logical scaffolding for more advanced analysis[6]. In this section, we elaborate on the key constructs: payoff matrix, pure strategy, mixed strategy, saddle point, and value of the game, each illustrated with a concise example for enhanced comprehension.

Payoff Matrix (A)

At the heart of any two-person zero-sum game is the payoff matrix, denoted by $A = [a_{ij}]$, which quantifies the strategic interaction between the two players—commonly referred to as Player A (the row player) and Player B (the column player). Each entry a_{ij} represents the payoff received by Player A when A selects strategy i and B selects strategy j. Since the game is zero-sum, the corresponding payoff to Player B is $-a_{ij}$, emphasizing that one player's gain is exactly the other's loss.

Example

Let

$A = \begin{bmatrix} 3 & -2 \\ 1 & 4 \end{bmatrix}$

Here, if Player A plays strategy 1 and Player B plays strategy 2, the payoff to A is −2-2−2, and to B is +2+2+2. This encapsulates the zero-sum nature.

Pure Strategy

A pure strategy is the most straightforward form of decision-making: a player selects a single action from their set of available strategies and plays it deterministically every time[7]. In matrix terms, this corresponds to choosing a particular row (for Player A) or column (for Player B) with probability 1. Pure strategies are optimal only when the game exhibits a saddle point—a condition that allows players to commit to deterministic behavior without risk of exploitation[8].

Example

Using the matrix above, suppose Player A always plays strategy 2, and B always plays strategy 1. The resulting payoff is $a_{ij} = 1$. This is a pure strategy outcome.

Mixed Strategy

A mixed strategy generalizes the notion of a pure strategy by introducing probabilistic behavior. Instead of committing to a single action, a player assigns a probability distribution over all possible actions. This allows for randomization, which can be essential in avoiding predictability and minimizing losses in the absence of a saddle point[9]. For Player A with m strategies, a mixed strategy is a vector $x = (x_1,x_2,...,x_m)$, where $xi \geq 0$ and $\sum x_i = 1$. Similarly, Player B's mixed strategy $y=(y_1,y_2,...,y_n)$ spans over n strategies.

The expected payoff to Player A when both players use mixed strategies x and y is given by

$E(x,y)=x^T Ay=\sum_{i=1}^{m}\sum_{j=1}^{n} x_i\, a_{ij}\, y_j$

Example

Let Player A use x=(0.4,0.6) x=(0.4,0.6) and Player B use y=(0.5,0.5) in the previous matrix. Then,

$(x,y)=(0.4,0.6)\begin{bmatrix}3 & -2\\ 1 & 4\end{bmatrix}\begin{bmatrix}0.5\\ 0.5\end{bmatrix} = (0.4,0.6)\begin{bmatrix}\frac{1}{2}\\ \frac{5}{2}\end{bmatrix} = 0.4\cdot 0.5 + 0.6 \cdot 2.5 = 0.2 + 1.5 = 1.7$

Thus, Player A expects a gain of 1.7 on average.

Saddle Point

A saddle point in the payoff matrix A is a strategy pair $(i^*,^*)$ such that

$a_{i^*j^*}=\min_j a_{i^*j^*} = \max_j a_{i^*j^*}$

This implies that $a_{i^*j^*}$ is simultaneously the minimum value in its row and the maximum in its column. When a saddle point exists, the corresponding pure strategies are mutually optimal, and the game has a pure strategy equilibrium.

Example

Consider the matrix

$\begin{bmatrix}2 & 1\\ 3 & 4\end{bmatrix}$

Row minima: min(2,1) = 1; min(3,4) = 3 → maximin = 3

Column maxima: max(2,3) = 3; max(1,4) = 4 → minimax = 3

Since maximin = minimax = 3, the saddle point exists at position (2,1), and the value of the game is 3.

Value of the Game

The value of the game, denoted V, is the expected payoff to the maximizing player (Player A) when both players use their optimal strategies. It represents the equilibrium outcome and characterizes the balance of strategic advantage[10].

If a saddle point exists, $V=a_{i^*j^*}$

If no saddle point exists, V is obtained by solving a minimax optimization problem, often requiring linear programming techniques.

The minimax theorem assures that

$\max_x \min_y x^T Ay = \min_y \max_x x^T Ay = V$

This result guarantees the existence of an equilibrium in mixed strategies, even in the absence of a saddle point.

Example

In the matrix

$A = \begin{bmatrix}1 & 2\\ 3 & 0\end{bmatrix}$

There is no saddle point. Solving via linear programming or graphical method might yield optimal mixed strategies $x*$ and$y*$, and a value V≈1.5. This is the amount Player A can expect to gain per play on average if both players act optimally. By grounding the analysis of two-person zero-sum games in these definitions, we obtain a precise language for modeling and solving adversarial situations. Whether in economics, computer science, or military applications, these constructs provide both the theoretical rigor and computational tools required to derive equilibrium behavior[11].

RESULT AND DISCUSSION

To illuminate the theory of two-person zero-sum games and its practical implications, we present a concrete example and conduct a detailed analysis. A central question in solving such games is whether a saddle point exists in the payoff matrix. This condition determines whether the game can be solved using pure strategies or whether mixed strategies are required to reach equilibrium. The saddle point acts as a pivot of strategic stability: if it exists, both players can settle on deterministic strategies with guaranteed outcomes[12].

Saddle Point Check

Let us consider the following game defined by the payoff matrix AAA, representing the payoffs to Player A (the maximizing player)

$A = \begin{bmatrix} 2 & -1 & 3 \\ 4 & 0 & 1 \end{bmatrix}$

This is a 2×3 matrix game in which Player A has two strategies (rows) and Player B has three strategies (columns). The entries in the matrix denote the payoff to Player A, and the negative of those values represent the corresponding losses for Player B due to the zero-sum property.

Step 1: Compute the Row Minimums (Maximin)

The row minimum represents the worst-case payoff for Player A if a given row (strategy) is chosen, assuming Player B counters optimally.

Row 1: min (2,−1,3) = −1

Row 2: min(4,0,1)=0

Then, the maximin value is

Maximin=max(−1,0)=0

This is the best worst-case outcome Player A can secure if forced to play a pure strategy without knowing B's choice.

Step 2: Compute the Column Maximums (Minimax)

The column maximum represents the worst-case loss for Player B (equivalently, the best possible gain for Player A) if a given column (strategy) is chosen.

Column 1: max(2,4)=4

Column 2: max(−1,0)=0

Column 3: max(3,1)=3

Then, the minimax value is

Minimax=min(4,0,3)=0

This is the least amount Player B can be forced to lose under the assumption that Player A acts optimally.

Step 3: Compare Maximin and Minimax

We now compare the two derived values:

Maximin = 0

Minimax = 0

Since maximin = minimax, the game possesses a saddle point. According to von Neumann's Minimax Theorem, this condition implies that both players have optimal pure strategies, and the game has a stable solution without requiring mixed strategies[13].

Step 4: Identify the Saddle Point

To locate the saddle point, we identify the entry (i,j) in the matrix that is simultaneously

- The minimum in its row, and
- The maximum in its column.

In this case, $a_{22}=0$ satisfies both conditions

It is the minimum in Row 2: (4,0,1)=0

- It is the maximum in Column 2: max(−1,0)=0

Hence, the saddle point occurs at position (2,2). The optimal strategies are

- Player A should choose Strategy 2 (Row 2).
- Player B should choose Strategy 2 (Column 2).

The value of the game is

$V=a_{22}=0$

This means that, under optimal play, Player A expects to win 0 on average, and the game ends in a strategic draw when both players play optimally.

Interpretation

The presence of a saddle point offers two crucial insights

Deterministic Stability: Neither player has an incentive to deviate from their optimal pure strategy. Player A guarantees a payoff of at least 0, and Player B limits potential losses to at most 0.

Strategic Simplicity: Unlike more complex games requiring randomization, this game can be fully solved through inspection of the payoff matrix. No linear programming or iterative algorithms are needed.

Such an outcome is not merely a computational convenience; it also reflects a kind of strategic symmetry in the conflict structure. Each player's optimal strategy aligns with a stable intersection in the matrix, making equilibrium behavior both predictable and enforceable.

Mixed Strategy Case (No Saddle Point)

While the presence of a saddle point in a two-person zero-sum game allows for a straightforward solution via pure strategies, not all games exhibit such structure. In fact, most real-world competitive scenarios lack a saddle point, requiring the use of mixed strategies to reach equilibrium. In such cases, optimal play for each player involves probabilistic randomization over their available actions, aiming to minimize predictability and guard against worst-case exploitation[14]. The Minimax Theorem, proven by John von Neumann in 1928, guarantees the existence of a value of the game and optimal mixed strategies for both players, even in the absence of a saddle point. These strategies form a Nash equilibrium in the context of zero-sum games, where no player can unilaterally improve their outcome[15].

No Saddle Point Exists

Let us consider the following 2×2 payoff matrix, where the entries represent the gains of Player A

$A = \begin{bmatrix} 3 & 1 \\ 0 & 2 \end{bmatrix}$

Step 1: Saddle Point Check

Compute row minimums and column maximums:

Row minimums: min(3, 1) = 1; min(0, 2) = 0 → maximin = max(1, 0) = 1

Column maximums: max(3, 0) = 3; max(1, 2) = 2 → minimax = min(3, 2) = 2

Since maximin ≠ minimax, no saddle point exists. Therefore, pure strategies are not sufficient, and players must resort to mixed strategies to determine optimal play.

Solving Using Mixed Strategies

Let

- Player A mix between Row 1 and Row 2 with probabilities x_1 and x_2, where $x_1+x_2=1$
- Player B mix between Column 1 and Column 2 with probabilities y_1 and y_2, where $y_1+y_2=1$

Let us denote the expected payoff to Player A as E(x,y). We aim to find x^* and y^* such that:

$\max_x \min_y E(x,y) = \min_y \max_x E(x,y) = V$

Step 1: Determine Player A's Mixed Strategy

Let Player A choose strategy 1 with probability xxx, and strategy 2 with probability 1 - x.

The expected payoff against Player B's pure strategies:

If B chooses Column 1: $E1(x)=3x+0(1-x)=3x$

If B chooses Column 2: $E2(x)=1x+2(1-x)=x+2-2x=2-x$

To find the optimal xxx, Player A equalizes both outcomes

$3x=2-x$

$\Rightarrow 4x=2$

$\Rightarrow x=\frac{1}{2}$

Therefore, the optimal mixed strategy for Player A is

$x*=(\frac{1}{2},\frac{1}{2})$

Step 2: Determine Player B's Mixed Strategy

Let Player B choose Column 1 with probability y, and Column 2 with probability $1-y$.

The expected loss (equivalently, Player A's gain) if Player A plays a pure strategy:

- **If A chooses Row 1:** $E1(y)=3y+1(1-y)=3y+1-y=2y+1$
- **If A chooses Row 2:** $E2(y)=0y+2(1-y)=2-2y$

Player B minimizes the maximum of these two expressions by equalizing them

$2y+1=2-2y$

$\Rightarrow 4y=1$

$\Rightarrow y=\frac{1}{4}$

Therefore, the optimal mixed strategy for Player B is

$y*=\left(\frac{1}{4}\frac{3}{4}\right)$

Step 3: Compute the Value of the Game

Substitute optimal strategies into the expected payoff function

$V=x^TAy=\left(\frac{1}{2},\frac{1}{2}\right)\begin{bmatrix}3 & 1\\ 0 & 2\end{bmatrix}\begin{pmatrix}\frac{1}{4}\\ \frac{3}{4}\end{pmatrix}$

Break this down:

$x^TA=\left(\frac{1}{2}.\ [3,1]+\frac{1}{2}.\ [0,2]\right)=[1.5,0.5]+[0,1]=[1.5,1.5]$

$V=[1.5,1.5]\cdot\begin{pmatrix}\frac{1}{4}\\ \frac{3}{4}\end{pmatrix}=1.5\cdot\frac{1}{4}+1.5\cdot\frac{3}{4}=\frac{3}{8}+\frac{9}{8}=\frac{12}{8}=1.5$

Thus, the value of the game is V=1.5.

Interpretation and Strategic Implications

This solution implies that, under optimal play

- Player A guarantees an average gain of 1.5 per play by randomising equally between strategies.
- Player B minimizes losses to 1.5 by assigning a 25% probability to Column 1 and 75% to Column 2.

The absence of a saddle point reflects the matrix's inherent asymmetry: no single strategy combination provides mutual best responses. Thus, optimal play must involve strategic unpredictability. This is central to modern strategic reasoning in competitive environments such as financial markets, security patrolling, and AI-based adversarial systems[16].

CONCLUSION

The optimal strategy in a two-person zero-sum game depends on the presence of a saddle point. If one exists, pure strategies are optimal. Otherwise, the use of mixed strategies through linear programming or the minimax theorem yields the equilibrium. The example games illustrate both scenarios, showing how values and strategies are derived.

ABSTRACT

In this study, the fundamental features and linkages of bipolar interval valued intuitionistic fuzzy mapping andbipolar interval valued intuitionistic fuzzy inverse mapping are introduced. Building on previous work in intuitionistic fuzzy graphs and interval-valued bipolar fuzzy sets, we develop these mappings and explore their properties. Important characteristics of these mappings are confirmed, laying the groundwork for upcoming uses in fuzzy graph theory and decision-making. By advancing fuzzy set theory, our work makes it possible to model complex systems and relationships in more sophisticated ways.

Keywords: Bipolar interval valued intuitionistic fuzzy mapping, Bipolar interval valued intuitionistic fuzzy inverse mapping, Bipolar interval valued intuitionistic fuzzy set, Bipolar interval valued intuitionistic fuzzy Topological Space.

INTRODUCTION

In 1965, L. A. Zadeh [36] developed and investigated the idea of a fuzzy subset. Numerous scientific and technical fields have found use for the ensuing research efforts in this and related fields. We were inspired to work on this paper by the following papers: As a generalization of topological spaces, fuzzy topological spaces were first

proposed and investigated by C. L. Chang [7] in 1968. This idea is popular among researchers, and numerous others have helped to create fuzzy topological spaces. In general topology, Dontchev [11] developed generalized semi-preclosed sets, while Andrijevic [1] introduced semi preclosed sets. Saraf and Khanna [25] then extended the collection to fuzzy topological spaces. The topology of interval valued fuzzy sets was introduced by Tapas Kumar Mondal and S. K. Samantha [22], whereas Jeyabalan R, Arjunan K, [14] presented interval valued fuzzy generalized semi-preclosed sets. Interval valued fuzzy generalized semi-preclosed and interval valued fuzzy generalized semi-preopen mappings are introduced in this study, along with some properties that are examined. Subsequently, S. Vinoth and K. Arjunan expanded interval valued fuzzy generalized semi pre continuous mapping into interval valued intuitionistic fuzzy generalized semi pre continuous mapping [27, 28]. The fuzzy set with interval values has been expandedinto the multifuzzy topological spaces with bipolar interval values. The concept of bipolar interval valued multifuzzy generalized semipreclosed sets was defined and presented by R. Selvam et al. [29]. Bipolar interval valued multifuzzy generalized semi-precontinuous mappings are introduced in this study, and some of their properties are examined.

2. Definition:

Let X be a non-empty set, and let A be a Bipolar interval valued intuitionistic fuzzy set of X in the form

$$A=\left\{\left\langle x,\left[\mu_{AL}^{p}(x),\mu_{AU}^{p}(x)\right],\left[\mu_{AL}^{N}(x),\mu_{AU}^{N}(x)\right],\left[\gamma_{AL}^{p}(x),\gamma_{AU}^{p}(x)\right],\left[\gamma_{AL}^{N}(x),\gamma_{AU}^{N}(x)\right]\right\rangle \mid x\in X\right\}$$

and let (X,τ_1) and (Y,τ_2) be two Bipolar Interval Valued Intuitionistic Fuzzy Topological Spaces (BIVIFTSs), and $f:X\to Y$ is a Bipolar Interval Valued Intuitionistic Fuzzy mapping, then the image f(A) of A under the Bipolar Interval Valued Intuitionistic Fuzzy mapping f which is in X is defined as

$$f(A)=\left\{\left\langle \begin{array}{l} x,\left[f\left(\mu_{AL}^{p}(x)\right),f\left(\mu_{AU}^{p}(x)\right)\right],\left[f\left(\mu_{AL}^{N}(x)\right),f\left(\mu_{AU}^{N}(x)\right)\right], \\ \left[f\left(\gamma_{AL}^{p}(x)\right),f\left(\gamma_{AU}^{p}(x)\right)\right],\left[f\left(\gamma_{AL}^{N}(x)\right),f\left(\gamma_{AU}^{N}(x)\right)\right] \end{array}\right\rangle \mid x\in X\right\}$$

where

$$f\left(\mu_{AL}^{P}(x)\right)=\begin{cases}\inf\limits_{x\in f^{-1}(y)}\mu_{AL}^{P}(x) & if \quad f^{-1}(y)\neq\phi \\ 0 & for \quad others\end{cases}$$

$$f\left(\mu_{AU}^{P}(x)\right)=\begin{cases}Sup\limits_{x\in f^{-1}(y)}\mu_{AU}^{P}(x) & if \quad f^{-1}(y)\neq\phi \\ 0 & for \quad others\end{cases}$$

$$f\left(\mu_{AL}^{N}(x)\right)=\begin{cases}\inf\limits_{x\in f^{-1}(y)}\mu_{AL}^{N}(x) & if \quad f^{-1}(y)\neq\phi \\ 0 & for \quad others\end{cases}$$

$$f\left(\mu_{AU}^{N}(x)\right)=\begin{cases}Sup\limits_{x\in f^{-1}(y)}\mu_{AU}^{N}(x) & if \quad f^{-1}(y)\neq\phi \\ 0 & for \quad others\end{cases}$$

$$f\left(\gamma_{AL}^{P}(x)\right)=\begin{cases}\inf\limits_{x\in f^{-1}(y)}\gamma_{AL}^{P}(x) & if \quad f^{-1}(y)\neq\phi \\ 0 & for \quad others\end{cases}$$

$$f\left(\gamma_{AU}^{P}(x)\right)=\begin{cases}\underset{x\in f^{-1}(y)}{Sup}\ \gamma_{AU}^{P}(x) & if \quad f^{-1}(y)\neq\phi\\ 0 & for \quad others\end{cases}$$

$$f\left(\gamma_{AL}^{N}(x)\right)=\begin{cases}\underset{x\in f^{-1}(y)}{\inf}\ \gamma_{AL}^{N}(x) & if \quad f^{-1}(y)\neq\phi\\ 0 & for \quad others\end{cases}$$

$$f\left(\gamma_{AU}^{N}(x)\right)=\begin{cases}\underset{x\in f^{-1}(y)}{Sup}\ \gamma_{AU}^{N}(x) & if \quad f^{-1}(y)\neq\phi\\ 0 & for \quad others\end{cases}$$

Example:

Let

$$A=\begin{Bmatrix}\langle a,[0.2,0.6],[-0.5,-0.2],[0,0.3],[-0.5,-0.1]\rangle,\\ \langle b,[0,0.3],[-0.6,0],[0.2,0.4],[-0.4,-0.2]\rangle\\ \langle c,[0.2,0.4],[-0.6,-0.3],[0.3,0.5],[-0.3,0]\rangle\end{Bmatrix}$$

$$B=\begin{Bmatrix}\langle a,[0.3,0.6],[-0.6,-0.3],[0.1,0.4],[-0.4,-0.2]\rangle,\\ \langle b,[0.4,0.5],[-0.5,-0.1],[0.2,0.5],[-0.5,-0.2]\rangle\\ \langle c,[0.2,0.4],[-0.7,-0.2],[0.3,0.6],[-0.3,-0.1]\rangle\end{Bmatrix}$$

be two bipolar interval valued intuitionistic fuzzy subset of X={a,b,c}.

Then the families $\tau_1=\{\tilde{0},\tilde{1},A\}$ and $\tau_2=\{\tilde{0},\tilde{1},B\}$ be two Bipolar Interval Valued Intuitionistic fuzzy Topological Space (BIVIFTS) of Bipolar Interval Valued Intuitionistic Fuzzy subsets of X.

Then the Bipolar Interval Valued Intuitionistic Fuzzy mapping $f:X\to Y$ which is in X is defined as

$$f(A)=\left\{\left\langle x,\begin{bmatrix}f\left(\mu_{AL}^{p}(x)\right),f\left(\mu_{AU}^{p}(x)\right)\end{bmatrix},\begin{bmatrix}f\left(\mu_{AL}^{N}(x)\right),f\left(\mu_{AU}^{N}(x)\right)\end{bmatrix},\right.\right.$$
$$\left.\left.\begin{bmatrix}f\left(\gamma_{AL}^{p}(x)\right),f\left(\gamma_{AU}^{p}(x)\right)\end{bmatrix},\begin{bmatrix}f\left(\gamma_{AL}^{N}(x)\right),f\left(\gamma_{AU}^{N}(x)\right)\end{bmatrix}\right\rangle \mid x\in X\right\}$$

$$\Rightarrow f(A)=\begin{Bmatrix}\langle a,[0.2,0.6],[-0.6,-0.2],[0,0.4],[-0.5,-0.1]\rangle,\\ \langle b,[0,0.5],[-0.6,0],[0.2,0.5],[-0.4,-0.2]\rangle,\\ \langle c,[0.2,0.4],[-0.7,-0.2],[0.3,0.6],[-0.3,0]\rangle\end{Bmatrix}$$

3. Definition:

Let X be a non-empty set, and let A be a Bipolar interval valued intuitionistic fuzzy set of X in the form

$$A=\left\{\left\langle x,\left[\mu_{AL}^{p}(x),\mu_{AU}^{p}(x)\right],\left[\mu_{AL}^{N}(x),\mu_{AU}^{N}(x)\right],\left[\gamma_{AL}^{p}(x),\gamma_{AU}^{p}(x)\right],\left[\gamma_{AL}^{N}(x),\gamma_{AU}^{N}(x)\right]\right\rangle \mid x\in X\right\}$$

$$B=\left\{\left\langle x,\left[\mu_{BL}^{p}(x),\mu_{BU}^{p}(x)\right],\left[\mu_{BL}^{N}(x),\mu_{BU}^{N}(x)\right],\left[\gamma_{BL}^{p}(x),\gamma_{BU}^{p}(x)\right],\left[\gamma_{BL}^{N}(x),\gamma_{BU}^{N}(x)\right]\right\rangle \mid x\in X\right\}$$

and let (X,τ_1) and (Y,τ_2) be two Bipolar Interval Valued Intuitionistic Fuzzy Topological Spaces (BIVIFTSs), and $f:X\to Y$ is a Bipolar Interval Valued Intuitionistic Fuzzy mapping, then the preimage $f^{-1}(A)$ of A under the Bipolar Interval Valued Intuitionistic Fuzzy inverse mapping f^{-1} which is in X is defined as

$$f^{-1}(A)=\left\{\left\langle x,\begin{matrix}\left[f^{-1}\left(\mu^{p}_{AL}(x)\right),f^{-1}\left(\mu^{p}_{AU}(x)\right)\right],\left[f^{-1}\left(\mu^{N}_{AL}(x)\right),f^{-1}\left(\mu^{N}_{AU}(x)\right)\right],\\ \left[f^{-1}\left(\gamma^{p}_{AL}(x)\right),f^{-1}\left(\gamma^{p}_{AU}(x)\right)\right],\left[f^{-1}\left(\gamma^{N}_{AL}(x)\right),f^{-1}\left(\gamma^{N}_{AU}(x)\right)\right]\end{matrix}\right\rangle \mid x\in X\right\}$$

where

$$f^{-1}\left(\mu^{p}_{AL}(x)\right)=\mu^{p}_{AL}(x)(f(x))$$
$$f^{-1}\left(\mu^{p}_{AU}(x)\right)=\mu^{p}_{AU}(x)(f(x))$$
$$f^{-1}\left(\mu^{N}_{AU}(x)\right)=\mu^{N}_{AL}(x)(f(x))$$
$$f^{-1}\left(\mu^{N}_{AL}(x)\right)=\mu^{N}_{AU}(x)(f(x))$$
$$f^{-1}\left(\gamma^{p}_{AL}(x)\right)=\gamma^{p}_{AL}(x)(f(x))$$
$$f^{-1}\left(\gamma^{p}_{AU}(x)\right)=\gamma^{p}_{AU}(x)(f(x))$$
$$f^{-1}\left(\gamma^{N}_{AU}(x)\right)=\gamma^{N}_{AL}(x)(f(x))$$
$$f^{-1}\left(\gamma^{N}_{AL}(x)\right)=\gamma^{N}_{AU}(x)(f(x))$$

Example:

Let

$$A=\left\{\begin{matrix}\langle a,[0.2,0.6],[-0.5,-0.2],[0,0.3],[-0.5,-0.1]\rangle,\\ \langle b,[0,0.3],[-0.6,0],[0.2,0.4],[-0.4,-0.2]\rangle\\ \langle c,[0.2,0.4],[-0.6,-0.3],[0.3,0.5],[-0.3,0]\rangle\end{matrix}\right\}$$

$$B=\left\{\begin{matrix}\langle a,[0.3,0.6],[-0.6,-0.3],[0.1,0.4],[-0.4,-0.2]\rangle,\\ \langle b,[0.4,0.5],[-0.5,-0.1],[0.2,0.5],[-0.5,-0.2]\rangle\\ \langle c,[0.2,0.4],[-0.7,-0.2],[0.3,0.6],[-0.3,-0.1]\rangle\end{matrix}\right\}$$

be two bipolar interval valued intuitionistic fuzzy subset of X={a,b,c}.

Then the families $\tau_1=\{\tilde{0},\tilde{1},A\}$ and $\tau_2=\{\tilde{0},\tilde{1},B\}$ be two Bipolar Interval Valued Intuitionistic fuzzy Topological Space (BIVIFTS) of Bipolar Interval Valued Intuitionistic Fuzzy subsets of X.

Then the Bipolar Interval Valued Intuitionistic Fuzzy mapping $f:X\to Y$ which is in X is defined as

$$f(A)=\left\{\left\langle x,\begin{matrix}\left[f\left(\mu^{p}_{AL}(x)\right),f\left(\mu^{p}_{AU}(x)\right)\right],\left[f\left(\mu^{N}_{AL}(x)\right),f\left(\mu^{N}_{AU}(x)\right)\right],\\ \left[f\left(\gamma^{p}_{AL}(x)\right),f\left(\gamma^{p}_{AU}(x)\right)\right],\left[f\left(\gamma^{N}_{AL}(x)\right),f\left(\gamma^{N}_{AU}(x)\right)\right]\end{matrix}\right\rangle \mid x\in X\right\}$$

$$\Rightarrow f(A)=\begin{Bmatrix}\langle a,[0.2,0.6],[-0.6,-0.2],[0,0.4],[-0.5,-0.1]\rangle,\\ \langle b,[0,0.5],[-0.6,0],[0.2,0.5],[-0.4,-0.2]\rangle,\\ \langle c,[0.2,0.4],[-0.7,-0.2],[0.3,0.6],[-0.3,0]\rangle\end{Bmatrix}$$

Then the Bipolar Interval Valued Intuitionistic Fuzzy inverse mapping $f^{-1}:Y\to X$ which is in X is defined as

$$f^{-1}(A)=\left\{\left\langle x,\begin{matrix}\left[f^{-1}\left(\mu^{p}_{AL}(x)\right),f^{-1}\left(\mu^{p}_{AU}(x)\right)\right],\left[f^{-1}\left(\mu^{N}_{AL}(x)\right),f^{-1}\left(\mu^{N}_{AU}(x)\right)\right],\\ \left[f^{-1}\left(\gamma^{p}_{AL}(x)\right),f^{-1}\left(\gamma^{p}_{AU}(x)\right)\right],\left[f^{-1}\left(\gamma^{N}_{AL}(x)\right),f^{-1}\left(\gamma^{N}_{AU}(x)\right)\right]\end{matrix}\right\rangle \mid x\in X\right\}$$

$$\Rightarrow f^{-1}(A)=\begin{Bmatrix}\langle a,[0.04,0.12],[-0.04,-0.03],[0,0.12],[-0.01,-0.25]\rangle,\\ \langle b,[0,0.15],[0,-0.36],[0.04,0.2],[-0.04,-0.16]\rangle,\\ \langle c,[0.04,0.16],[-0.06,-0.42],[0.09,0.3],[0,-0.09]\rangle\end{Bmatrix}$$

4. Preposition:

Let X be a non-empty set, and let A and B be any two Bipolar interval valued intuitionistic fuzzy set of X in the form

$$A=\left\{\left\langle x,\left[\mu^{p}_{AL}(x),\mu^{p}_{AU}(x)\right],\left[\mu^{N}_{AL}(x),\mu^{N}_{AU}(x)\right],\left[\gamma^{p}_{AL}(x),\gamma^{p}_{AU}(x)\right],\left[\gamma^{N}_{AL}(x),\gamma^{N}_{AU}(x)\right]\right\rangle \mid x\in X\right\}$$

$$B=\left\{\left\langle x,\left[\mu^{p}_{BL}(x),\mu^{p}_{BU}(x)\right],\left[\mu^{N}_{BL}(x),\mu^{N}_{BU}(x)\right],\left[\gamma^{p}_{BL}(x),\gamma^{p}_{BU}(x)\right],\left[\gamma^{N}_{BL}(x),\gamma^{N}_{BU}(x)\right]\right\rangle \mid x\in X\right\}$$

and let (X,τ_1) and (Y,τ_2) be two Bipolar Interval Valued Intuitionistic Fuzzy Topological Spaces (BIVIFTSs), and $f:X\to Y$ is a Bipolar Interval Valued Intuitionistic Fuzzy mapping, then

i. If $A\subseteq B$ then $f^{-1}(A)\subseteq f^{-1}(B)$

ii. $A\subseteq f\left(f^{-1}(A)\right)$ and if f is injective then $A=f\left(f^{-1}(A)\right)$

iii. $f\left(f^{-1}(A)\right)\subseteq A$ and if f is surjective then $f\left(f^{-1}(A)\right)=A$

iv. $f^{-1}(A\cup B)=f^{-1}(A)\cup f^{-1}(B)$

v. $f^{-1}\left(\bigcup_{i\in J}A_i\right)=\bigcup_{i\in J}f^{-1}(A_i)$

vi. $f^{-1}(A\cap B)=f^{-1}(A)\cap f^{-1}(B)$

vii. $f^{-1}\left(\bigcap_{i\in J}A_i\right)=\bigcap_{i\in J}f^{-1}(A_i)$

viii. $f^{-1}(A)=0$ if and only if $A\cap f(1)=0$

CONCLUSION

In segment2Bipolar interval valued intuitionistic fuzzy mapping is defined with an example. and in part3Bipolar interval valued intuitionistic fuzzyinverse mapping concepts that we have successfully proposed and investigated in this article. In Section 4 some of the basic properties of Bipolar interval valued intuitionistic fuzzy inverse mapping are verified. By establishing these mappings and confirming their essential characteristics, we have established the foundation for additional study and use in fuzzy set theory, graph theory, and decision-making. The suggested mappings offer a strong foundation for managing ambiguity and uncertainty, allowing for more intricate modeling of intricate linkages and systems. The study's conclusions have important significance for a number of domains, such as fuzzy graph theory, pattern recognition, and decision-making. Applications of fuzzy graph theory in social network analysis, pattern recognition in image processing, and decision-making under uncertainty are just a few examples of real-world issues that can be modeled using the bipolar interval valued intuitionistic fuzzy mapping and inverse mapping.

6. Future Work:

Future research directions may include:

- Investigating the applications of bipolar interval valued intuitionistic fuzzy mapping and inverse mapping in specific domains, such as decision-making, pattern recognition, and fuzzy graph theory.
- Developing new properties and operations for these mappings, such as composition, union, and intersection operations.
- Exploring the relationships between bipolar interval valued intuitionistic fuzzy mapping and other types of fuzzy mappings, such as intuitionistic fuzzy mappings and interval-valued fuzzy mappings.

- Investigating the potential applications of bipolar interval valued intuitionistic fuzzy mapping and inverse mapping in real-world problems, such as decision-making under uncertainty and pattern recognition in image processing.

ABSTRACT

In the evolving field of communication systems, accurate signal classification plays a crucial role in ensuring robust performance, particularly in noisy environments. In this paper, we introduce DeepWaveSense a Convolutional Neural Network (CNN)-based model designed to classify waveform signals with high precision. Our model effectively differentiates between pure Frequency Shift Keying (FSK), FSK signals with noise, and pure noise across a range of Signal-to-Noise Ratios (SNR) from +20 dB to -20 dB. By transforming waveforms into images and leveraging advanced deep learning techniques, we enable our CNN to detect and classify signal types with remarkable accuracy. Our experimental results demonstrate the model's strong performance in challenging noisy conditions, highlighting its potential to improve classification accuracy in real-world applications. This work contributes to the advancement of signal processing in digital communication systems, showcasing the ability of deep learning to enhance noise resilience and waveform recognition.

Keywords: Frequency Shift Keying, Spectrum Sensing, Waveforms, Deep Learning, Convolutional Neural Network

INTRODUCTION

In modern communication systems, the accurate classification and detection of signals are crucial for reliable data transmission, especially in noisy environments. The presence of noise can significantly degrade signal quality, making it difficult to differentiate between different types of signals. One of the widely used modulation techniques in communication systems is Frequency Shift Keying (FSK), where the frequency of a carrier signal is shifted to represent digital data. While FSK is relatively robust against noise compared to other modulation schemes, the accuracy of signal detection and classification can still be compromised, particularly when the signal-to-noise ratio (SNR) is low. Traditional methods of signal classification often struggle in noisy conditions, limiting the efficiency and reliability of communication systems. However, recent advances in deep learning, particularly Convolutional Neural Networks (CNNs), have shown promise in solving complex signal processing challenges. CNNs have demonstrated their effectiveness in tasks such as image recognition and are now being applied to signal classification, offering the potential to overcome noise-related issues and improve overall accuracy. In this paper, we propose DeepWaveSense, a CNN-based model specifically designed for the classification of waveform signals. Our model is trained to distinguish between pure FSK, FSK with noise, and pure noise across a range of Signal-to-Noise Ratios (SNR) from +20 dB to -20 dB. By transforming waveform data into images, we leverage the power of CNNs to detect and classify these signals with high accuracy, even in challenging noisy environments. The experimental results demonstrate that DeepWaveSense outperforms traditional signal classification methods, particularly in scenarios with low SNR. This work contributes to the field of signal processing in digital communication systems, highlighting the effectiveness of deep learning models in enhancing noise robustness and improving waveform recognition in real-world applications.

Traditional Works

In the field of signal classification, traditional methods have predominantly relied on statistical and signal processing techniques to distinguish between different types of signals. Techniques such as thresholding, matched filtering, and spectral analysis were initially used to classify signals based on their frequency, amplitude, and phase characteristics. These methods were particularly effective in environments with high signal-to-noise ratios (SNR), where the signal could be clearly separated from noise. However, these methods face significant challenges in noisy environments, particularly when dealing with complex signal types like Frequency Shift Keying (FSK), where noise interferes with the signal's characteristics, causing classification errors. As signal processing techniques advanced, methods such as Fourier transforms and wavelet transforms were employed to analyze the frequency components of signals and improve classification performance. These techniques helped improve the separation of the signal from noise by providing a more detailed representation of the signal's frequency spectrum. Despite their success in ideal conditions, these methods continued to struggle in low SNR environments, where noise distortion significantly impacted signal clarity and made accurate classification difficult. With the introduction of machine learning techniques, models like support vector machines (SVMs) and decision trees were explored to enhance classification accuracy in noisy environments. These models allowed for better classification by learning from data and making predictions based on observed patterns. However, these methods often required significant manual feature extraction, making them computationally expensive and less efficient when dealing with large, high-dimensional datasets. Moreover, their performance was still suboptimal when confronted with noisy or complex signal conditions.

Problem Formulation

The problem addressed in this research focuses on the challenge of classifying Frequency Shift Keying (FSK) waveforms under varying noise conditions[3]. FSK is a widely used modulation technique in communication systems, where the frequency of a carrier signal is shifted according to the data being transmitted. However, FSK signals are often subject to noise interference, which can degrade the performance of traditional classification methods. In particular, techniques like matched filtering, thresholding, and spectral analysis fail to maintain accuracy under low Signal-to-Noise Ratios (SNR), which are common in real-world environments[4]. The goal of this research

is to design a robust, scalable, and automated classification system using Convolutional Neural Networks (CNNs) to distinguish between pure FSK signals, FSK with noise at different SNR levels (from +20 dB to -20 dB), and pure noise. Traditional methods rely heavily on manual feature extraction, which can be limited in noisy environments. CNNs, on the other hand, have the advantage of automatically learning discriminative features from raw data, making them ideal for waveform classification tasks. The proposed CNN model aims to improve classification performance by leveraging deep learning techniques to handle noisy waveforms across varying SNRs. By automatically extracting relevant features from spectrograms or time-frequency representations of the waveforms, the model will be able to achieve higher accuracy and robustness compared to traditional approaches. We design a deep Convolutional Neural Network (CNN) architecture with a focus on efficient feature extraction, noise resilience, and generalization capability.

Filter Selection: The architecture employs 3x3 convolutional filters in each layer, enabling the model to capture localized patterns while maintaining spatial resolution. These small kernels also help reduce the number of parameters, making the model more computationally efficient[5].

Channel Consideration and Management: The model increases the number of filters in successive layers (32, 64, 128), allowing it to progressively capture richer and more abstract features. This controlled expansion in channels enables the extraction of both low-level edges and high-level signal characteristics.

Pooling Strategy: MaxPooling layers with a 2x2 window are integrated after each convolutional block to downsample the feature maps[6]. This reduces dimensionality, highlights dominant features, and improves computational performance.

Normalization and Activation: Batch Normalization is applied after each convolution to stabilize the training dynamics and normalize intermediate outputs. ReLU is used as the activation function to introduce non-linearity, ensuring the model learns complex transformations. A Softmax layer at the end outputs the class probabilities.

Filter Evolution and Layer Expansion: The depth of the network increases gradually, along with the number of filters per layer. This allows for hierarchical learning—starting from basic waveform patterns in early layers to more abstract and noise-invariant representations in deeper layers[7].

Overfitting Control: A Dropout layer is applied in the fully connected section of the model to mitigate overfitting. By randomly deactivating neurons during training, the model is encouraged to generalize better and avoid reliance on specific paths.

Architectural Inspiration: The model design draws conceptual inspiration from established CNN frameworks, adopting principles of depth, regularization, and modular convolutional blocks to maintain balance between complexity and generalization[8].

CNN - Based Solution

In this research, we introduce *DeepWaveSense*, a convolutional neural network-based model designed to classify waveform images into three distinct categories: pure FSK, FSK with noise, and pure noise[9]. Departing from traditional approaches that depend on spectrograms or frequency-domain transformations, our method leverages raw waveform plots, preserving the signal's temporal structure and minimizing preprocessing requirements. This design choice enhances the model's suitability for real-time signal classification systems. The architecture of DeepWaveSense comprises a sequential stack of convolutional layers, each designed to capture progressively complex features such as signal patterns, line continuity, and disruptions caused by noise. Batch normalization is applied after each convolution to stabilize training, while non-linear activation functions improve the model's ability to learn intricate patterns[10]. Pooling layers are strategically placed to reduce spatial dimensions, enhance generalization, and lower computational complexity. As the network deepens, filter complexity increases to

transition from low-level to high-level feature recognition. The final stages include a flattening layer followed by a dense layer, with dropout regularization introduced to prevent overfitting. A softmax output layer ensures accurate classification into the predefined waveform categories[11]. DeepWaveSense integrates well-established CNN principles with careful design choices in layer structure, activation, normalization, and regularization. The result is a robust and efficient model capable of accurately classifying noisy and modulated signals directly from waveform images. Summary of Model Architecture (Table 1).

Performance Evaluation

Generating Simulated Data

In the field of spectrum sensing, obtaining high-quality labeled data is essential for effectively training and evaluating machine learning models. This paper delves into the critical aspect of data generation, presenting a novel methodology for generating synthetic data that meets the complex requirements of spectrum sensing tasks[12]. The objective is to produce a versatile dataset capable of supporting robust model development and comprehensive performance evaluation[13].

To generate the dataset for our experiments, we focus on three classes of FSK signals

Pure FSK: These signals consist of frequency-shift keyed data without any additional noise. The goal is to represent ideal conditions where only the FSK signal is present.

FSK with Noise: In this class, we introduce white Gaussian noise (AWGN) to the FSK signals, simulating real- world scenarios where signals may be affected by environmental factors or interference[14]. The noise is added to challenge the model's ability to distinguish between the original signal and noise.

Pure Noise: This class represents pure noise with no underlying signal[15]. It serves as a control to ensure that the model can effectively differentiate noise from actual signal components[16]. These three classes of signals are generated using waveform data, where each signal is constructed by modulating data with FSK, then adding varying levels of noise for the noisy class. The dataset is designed to facilitate the development of spectrum sensing models that can handle both clean and noisy environments[17]. Through this methodology, we aim to create a rich, adaptable dataset that enables rigorous testing of spectrum sensing algorithms, ensuring they are robust and generalizable to different real-world conditions.

Training Process

Training accuracy is a key metric to evaluate the performance of a model during the training process. It is the proportion of correctly classified samples relative to the total number of training samples[18]. In this study, we track the training accuracy achieved during the training of our spectrum sensing model over 15 epochs. The x-axis of the graph corresponds to the number of epochs, while the y-axis represents the accuracy values. These graphs are essential for understanding the model's learning behavior, identifying any overfitting or underfitting tendencies, and determining the optimal number of epochs for training. Figure 4 shows the training versus validation accuracy for the dataset with a fixed modulation order[19]. The graph indicates that both training and validation accuracy increase steadily as the model learns, with validation accuracy reflecting similar trends to training accuracy. Additionally, both the training and validation loss decrease as the number of epochs increases, indicating that the model is effectively learning the features from the dataset within 15 epochs. Pure FSK Waveform (Fig.1). NoiseWaveform(AWGN) (Fig.2). FSK with NoiseWaveform (Fig.3).

Transfer Learning for better result

In this study, we incorporate the pre-trained InceptionV3 model to enhance feature extraction for signal classification. Known for its efficiency and multi-scale feature learning, InceptionV3 uses a combination of 1x1, 3x3, and 5x5 convolutions within the same module. This design allows the model to capture both fine and broad patterns while maintaining computational efficiency. The outputs of these diverse filters are concatenated, enabling the network to learn comprehensive representations across multiple scales. This parallel processing approach

significantly improves the model's ability to generalize and recognize complex patterns in input data[20]. For our task, we apply transfer learning by using the InceptionV3 model pre-trained on ImageNet. We remove the top classification layers and freeze the base model's weights to retain learned features. On top, we add a global average pooling layer, dense layers with ReLU activation, dropout for regularization, and a softmax layer for final classification. This setup ensures robust, efficient, and accurate performance tailored to our spectrum sensing application. The model is compiled with categorical cross-entropy loss and the Adam optimizer, with accuracy used as the evaluation metric[21]. Early stopping and model checkpointing callbacks are employed to monitor the validation accuracy and loss, ensuring model convergence while preventing overfitting. The model is trained on the provided dataset for 15 epochs, with validation data used for evaluation during training. While the InceptionV3 module demonstrates impressive performance on the provided dataset, it is important to consider the computational resources required for training and inference. Pre-trained models like InceptionV3 can be computationally expensive, especially when deploying on resource-constrained devices or in real-time applications. However, their ability to achieve high accuracy and fast convergence makes them a valuable tool in complex tasks like spectrum sensing. Although the InceptionV3-based model yields superior results in terms of accuracy, a custom model, tailored specifically for the task at hand, might offer unique advantages in terms of interpretability, flexibility, and resource efficiency. In our experiments, the custom model demonstrated competitive performance, making it an excellent alternative for practical, real-time spectrum sensing applications where resources may be limited.

Technology Used

The study was implemented in Python, using TensorFlow and Keras to design, train, and evaluate a CNN model. NumPy was used for numerical computations, while OpenCV handled image preprocessing. Model performance was tracked with Matplotlib, and training was accelerated using an NVIDIA T4 GPU on Google Colab. Data and file management were done via Google Drive integration. The final model was saved as "DeepWaveSense.h5" for future use.

Testing Field Data

The model was tested using a carefully designed dataset to evaluate its ability to classify images into three categories: pure FSK, FSK with noise, and pure noise. To ensure a thorough assessment, the FSK with noise category included signal-to-noise ratios (SNR) ranging from 20 dB to -20 dB, covering a wide range of noise levels. Testing was carried out in two key scenarios: a controlled environment to measure baseline performance and a real-world environment to evaluate how well the model performs under practical conditions. Predicted output for pure FSK sample (Fig. 5). Predicted output for FSK with noise sample (Fig. 6). Predicted output for pure noise sample (Fig. 7). The results showed that the model was highly accurate in identifying and distinguishing between the three categories, even under varying noise levels[22]. These findings confirm its reliability and robustness for real-world applications.

CONCLUSION

The testing phase confirmed that the model performs effectively across the entire range of SNR values from 20 dB to -20 dB. The model maintained a high level of accuracy even under challenging noise conditions, showcasing its potential for spectrum sensing and signal classification applications. Future work will focus on further enhancing the model's robustness, particularly in extreme noise environments.

ABSTRACT

A bush graph, in the context of graph theory, refers to a specific type of graph structure that resembles a bush or a tree with additional connections. These graphs are characterized by a central "trunk" or root from which "stems" extend to other vertices. Each of these vertices is a leaf of a stem from root vertex and it may act as an extended root. These vertices may have further branching or connections. They are often used in the study of graph classes with bounded expansion and in the context of knowledge representation. This paper provides the results of a combinatorial study and interpretation of three-dimensional bush graphs and their applications.

Keywords: Bush Graph, Graph Theory, Tree, Root Vertex.

INTRODUCTION

A bush B consists of a rooted tree T in which all leaves have equal depth. The leaf set of T is denoted by Leaves(B), and the set of nodes of T is denoted by V(B). The depth of B is the depth of T. A symmetric, reflexive binary relation $I \subseteq V(B)\times V(B)$, whose elements are called 'info arcs', and are such that both endpoints have equal depth in T. This depth is the depth of an info arc. A labelling function λ: Leaves(B) $\rightarrow\Lambda$, where Λ is a finite set of labels and another labelling function is defined as λ^I: $I \rightarrow 2^{\Lambda\times\Lambda}$.Figure 1 shows one unlabelled 3D bush graph, two labelled 3D graphs and one 4D hyper bush graph. Let us consider the case of the set of 4-vertex labelled bush graphs. One vertex out of four is treated here as root vertex. One can construct a total of 56 bush graphs for a single root vertex, and 224 bush graphs for all four vertices. Let vertex 1 be the root (V(B) = 1) and vertices 2, 3 and 4 be the leaves, such that Leaves(B) = {2, 3,

4}. For the 4-vertex graph, one can construct 7 trees with directed edges (stem edges) and 8 info arcs (undirected edges)

Number of trees $= \sum_{k=1}^{3} \binom{3}{k} = 3 + 3 + 1 = 7$

NOTE: Without stem edge(s) of a root vertex, one cannot construct bush graphs.

Number of info arcs (undirected edges) $= \sum_{k=0}^{3} \binom{3}{k} = 1 + 3 + 3 + 1 = 8$

Total number of concrete 3D bush graphs = 8×7 =56. One can construct four such sets of 3D bush graphs by treating one of the four vertices as root vertex. This means that one can have 56×4 = 224 concrete 3D bush graphs using four vertices. In the above case, vertex 1 was considered as the root and vertices 2, 3 and 4 as leaves at level 1, such that (V(B1) = 1) and the set Leaves(B1) = {2, 3, 4}. A total of 224 bush graphs could be constructed by treating all four vertices as root vertex, one at a time. A multi-level 3D tree graph will have level 0 root vertex called 'Seed' and a finite number of levels with finite number of vertices.

This paper examines the possibilities of characterizing multi-level 3D tree and bush graphs, keeping a single vertex as 'Seed' at level 0 and multiple vertices at every level.

Three-Dimensional Tree and Bush Graphs - Preliminaies

Any 3D tree or bush graph essentially expands from a root vertex called 'seed'. The first level 3D graph may have many vertices and the set of first level vertices is denoted by V(B1). Let us consider a root vertex 1 and three vertices 2, 3 and 4 in the first level so that V(B1) = {2, 3, 4}. All the 56 bush/tree graphs for a singly root vertex are shown below in table 1. All the vertices are shown here as shaded spheres.

Multi-Level Three-Dimensional Tree and Bush Graphs

Let us consider the case of a three-level 3D tree/bush graph with seed vertex labelled as 0 at level 0. Figure 2 shows the three-level complete tree and bush graphs. Table 2 shows vertices at different levels. The seed is denoted as '0'. Labelling of vertices follows the procedure given below. Consider the vertex 110 shown in figure 2. The first '1' refers to level number. The second '1' refers to the vertex number at level 1 and the third '0' refers to the seed at level 0. In the same manner vertices at higher levels are also labelled. For example, the vertex 21110 at level 2 is interpreted as follows. The first '2' refers to the second level. The second '1' refers to the vertex number and the string '110' refers to its root vertex at level 1. The vertex 312110 at level 3 is interpreted as follows. The first number '3' refers to level number. The second '1' refers to the vertex number and the string '21110' refers to its root vertex.

Basic Assumptions

The tree and bush graphs shown in figure 2 have been developed based on the following assumptions:

1. Level 1 has three vertices V(B1) = {110, 120, 130}
2. Each level 1 vertex is viewed as a root vertex for second level expansion.
3. Each level 2 vertex is viewed as a root vertex for third level expansion. This could be generalized for further multi-level expansions.
4. Each root vertex is of degree 3, irrespective of the level.
5. Each root vertex yields three sparse graphs.

Concept of Inter Sparse Graph info arcs

Consider level 2 sparse graphs shown in figure 3.A total of 27 info arcs between level 2 sparse graphs are shown in figure 3. One can have $\sum_{k=0}^{27} \binom{27}{k}$=

1+27+351+2925+17550+80730+296010+888030+2,220,075+4,686,825+8,436,285+13,037,895+17,383,860+20,058,300+20,058,300+17,383,860+13,037,895+8,436,285+4,686,825+2,220,075+888,030+296,010+80,730+17,550+2,925+351+27+1=**13,42,17,728**number of info arcs between three sparse graphs the at level 2.

Similarly, one can construct a total of 3^9 = 19,683inter info arcs between 9 sparse graphs at level 3. This means that one can construct $\sum_{k=0}^{19,683}\binom{19,683}{k}$= number of inter info arcs combinations between nine sparse graphs at level 3.

Pine tree graphs

A sparse graph at level 3 has a root vertex at level 2 and the sparse graph with reference to that vertex has its root vertex at level 1, which is connected to seed vertex at level 0. The graph connecting level 1 to level 3 sparse graphs is called 'pine tree graph'. Figures 3(a) and 3(b) show two examples of pine tree graphs up to level 3 among a total of 9 pine tree graphs. Note that root vertices of degree 3 up to a 'L' level will yield $3^{(L-1)}$ pine tree bush graphs.

Multi-Level Tree and Bush Graphs with Root Vertices of Variable Degrees

One can construct multi-level tree graphs with reference to the level 0 root vertex, as follows. Assume the seed vertex of degree N1, which means that the number of vertices at level 1 is N1. Then the number of trees is given by the formula

$$\text{Number of trees} = \sum_{k=1}^{N1}\binom{N1}{k}$$

Then the number of info arcs among N1 vertices (110, 120, 130, …1N10) is given by the formula

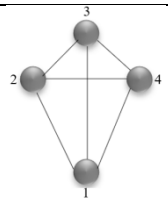
$$\text{Number of info arcs} = \sum_{k=0}^{N1}\binom{N1}{k}$$

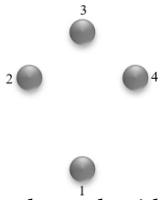
Total number of concrete bush graphs at level 1 is given by the formula

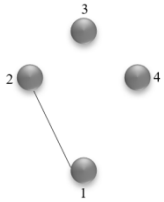
$$\text{Total number of bush graphs at level 1} = \sum_{k=1}^{N1}\binom{N1}{k}\times\sum_{k=0}^{N1}\binom{N1}{k}$$

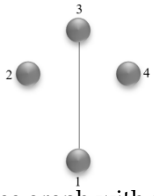
Each of the N1 vertices at level 1 is a root vertex of degree N1, which means that the total number of vertices at level 2 is $(N1)^2$. Note that root vertices of degree N1 up to a 'L' level will yield $(N1)^{(L-1)}$ pine tree bush graphs.

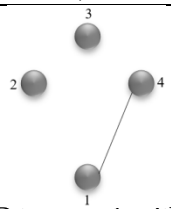
CONCLUSIONS

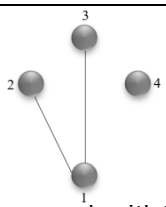


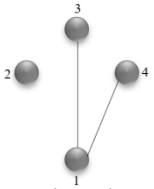


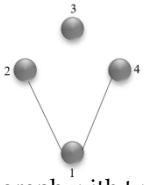


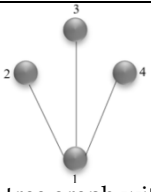


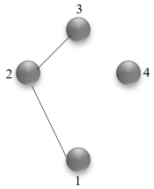


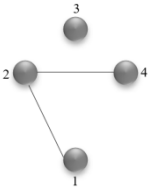


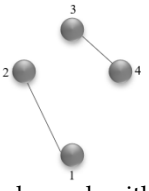












The concept of multi-level tree and bush graphs is introduced in this paper. A combinatorial study of multi-level bush graphs has been carried out and results reported. This study is expected to open up new avenues in the area of knowledge representation, data analytics, communication networks, neural networks, artificial intelligence and cognitive study of consciousness.

 3D bush graph with three stem edges: <1,2>, <1,3>, <1,4> and two info arcs: <2,4>, <3,4>	It is clear that one can construct a total of seven trees with stems extending from root vertex 'Seed' at level 0 given by the formula $\sum_{k=1}^{3}\binom{3}{k}$. One can as well construct eight info arcs between the three vertices V(B1) = {2, 3, 4} as per the formula: $\sum_{k=0}^{3}\binom{3}{k} = 1+3+3+1 = 8$. The criterion of k = 0 refers to the case of all three vertices at level 1 are connected to root vertex at level 0. The criterion k= 3 refers to the case of all three vertices are connected by a total of three info arcs and three stem edges. Without any info arc, the graph remains a tree, whereas the presence of at least one info arc makes the tree structure a bush structure. The question that arises here is whether one can develop multi-level tree and bush graphs, and the answer is affirmative. This paper is mainly concerned with the combinatorial construction of multi-level three-dimensional bush graphs and graph theoretic study of their structural properties.

ABSTRACT

A major part of the global carbon cycle is soil organic carbon content, which is essential to enhance soil fertility and reduce the effect of climate change. Any changes in the land-use pattern of the riparian areas can greatly influence the soil carbon pool hence, periodic field-level assessments are essential to understand these impacts. This study was conducted in the Riparian zone of the Lower Narmada Basin to assess Soil Organic Carbon Stocks (SOCS). The study analyzed 39 plots and found Soil Organic Carbon % content of 1.3 ± 0.37%, Bulk density of 1.01 ± 0.3 gm/cm^3 and Soil Organic Carbon Stocks (SOCS) of 39.68 ± 17.85 Mg/ha, indicating moderate to high carbon sequestration potential which is mostly impacted by agricultural activities in the river buffer zones. Statistical analysis shows a significant positive correlation between SOC % and SOCS, while no correlation between Bulk density and SOCS. The multiple regression model indicates that SOC % and Bulk density together explains 98.6% of the variations found in soil organic carbon stocks (SOCS).

Keywords: Riparian zones, Lower Narmada Basin, Bulk density, sSoil Organic Carbon Stocks.

INTRODUCTION

Riparian zones play an important role in linking terrestrial and aquatic ecosystems and serves as a critical corridor for the exchange of material, energy and nutrients [1]. According to the Intergovernmental Panel on Climate Change [2]a terrestrial ecosystem contains five carbon pools: above-ground biomass, below-ground biomass, litter, deadwood and soil organic carbon. Among these Soil Organic Carbon (SOC) in the riverine area is a key indicator of soil quality and ecosystem health because it directly influences soil fertility, water retention and soil microbial diversity [3, 4]. The carbon stocks in the riparian area contribute significantly to the global carbon cycle and serve as an essential mechanism for mitigating climate change through carbon sequestration and even minor changes in the SOC pool in the riparian system can have a significant impact on greenhouse gas emissions [1, 4,5]. Usually the tidal and riverine ecosystems typically exhibit higher SOC stocks due to waterlog conditions that slower the decomposition rate, allowing organic matter to accumulate [6]. Additionally, these areas often experience dynamic hydrological processes such as flooding and sediment deposition which enhance nutrient availability and organic carbon storage which promotes soil fertility [7]. Despite the ecological importance of river buffers in sequestering carbon, there is limited research on soil carbon stocks in major river systems of India like the Narmada. The primary objective of this study was to estimate the Soil Organic Carbon Stocks within the riparian zones of Narmada River.

MATERIALS AND METHODS

Study area and Sampling design

The Narmada river basin is known for its varied landforms and is a significant lifeline for central and western India [8]. Known as the fifth largest river as per basin area and sixth longest river in the country, the Narmada transverses through a tectonic rift valley flanked by the Vindhya and Satpura ranges and ultimately merges into the Arabian Sea [9, 10]. Historically known as “Reva” and “Narbada,” this monsoon-fed river supports various ecosystems mainly consisting of 56.9% agriculture land and 32.88% of forest cover [10, 11]. The basin area of the river has been divided into three sub-basins: Upper basin, Middle basin and Lower basin, which are encompassed by 150 watersheds and 19 major tributaries [8, 10]. The Lower Narmada basin consists of 61% area of agricultural land, 21% area of dense forest vegetation and 8% area of urban development according to the land use and land cover (LULC) classifications [12]. In the present study, the riparian area of the Lower Narmada basin is studied for Soil Organic Carbon Stocks (SOCS). The optimal buffer width for river corridor is not fixed but changing depending upon the study objectives [13], for this research a 1 km river buffer was delineated for the Lower Narmada basin area using QGIS 3.42 software, based on river line vector data obtained from National wetland Inventory under SARITA (Satellite based River hydro logical Techniques and Application) which is available on VEDAS portal for visualization (https://vedas.sac.gov.in)[11,14]. The soil sample data is collected from 39 pre-decided plots to calculate Soil organic carbon. The soil organic matter tends to accumulate in the upper soil horizons, with approximately 50% of SOC in the top 100 cm of which 30cm is of mineral soil so up to 30cm depth soil samples are collected for the study [2] using a standardized 300 cm^3 metal soil sampling corer samples at three depth intervals of 0–10 cm, 11–20 cm and 21–30 cm are collected in an airtight zip lock bags to avoid any contamination. This stratified approach helps understandthe SOC% distribution across the surface soil profile [3].

Soil analysis

The soil testing was conducted at laboratory of the Department of Botany, Gujarat University laboratory for the estimation SOCS along with two key parameters bulk density and SOC % concentration, which are calculated by using standard protocols of Food and Agriculture Organization (FAO)[15,16]. The Bulk density is a crucial physical property of soil that reflects soil structural conditions. Higher bulk density indicate restricted root growth and poor aeration, while lower values indicate healthy soil structure and higher water retention capacity [4]. The standard unit of its measurement is g/cm^3. The Soil Organic Carbon (SOC %) is estimated using the Walkley-Black titration method according to Food and Agriculture Organization protocols [16] (Figure 1).The Soil Organic Carbon Stock (SOCS) is

then computed using the formula by Karki*et.al.,*2016providing an integrated measure of carbon sequestration potential across all the soil samples [17].

SOC Stock (tons/ha) = ϱ x SOC (%) x D

Where SOC stock = soil organic carbon stocks

ϱ = Soil bulk density (g cm^3)

% SOC = Organic Carbon concentration

D = Total depth at which the sample was taken [cm] - 30 cm

Data analysis

Linear regression between bulk density and SOC (%) and linear regression between Bulk densities with SOCS is performed. Further Multiple linear regression is conducted to examine the influence of SOC (%) and Bulk density on SOCS (Mg/ha). The analysis is conducted in R-Studios where model fit is calculated using R^2 and adjusted R^2 values. The residual diagnostics like normality, homoscedasticity and outlier detection are evaluated using standard diagnostic plots, with significance set at $p < 0.05$.

RESULTS AND DISCUSSION

Bulk Density (g/cm^3)

Table 1 illustrates the bulk density of riparian soils in the lower Narmada basin, which ranges from 0.35 g/cm^3 (PC-5) to 1.83 g/cm^3 (PC-33). Variations in bulk density are influenced by factors such as soil compaction, consolidation and the amount of organic carbon.

Soil organic carbon (SOC %)

According to literature the SOC (%) values between 0.0 to 0.50 indicate a much lower amount of carbon, 0.51 to 0.75 indicates a moderate amount, 0.76 to 1.25 indicate a high availability of carbon in soils, values from 1.26 to 1.50 show very high organic carbon and higher than 1.50 show extremely high soil carbon [18]. The SOC % in current study area range from 0.51% to 2.2% indicating four category ranges except for the much lower carbon-containing class I (table 1). Out of the 39 plots analyzed, 03 plots exhibited a moderate range of soil organic carbon, 18 plots fell within the higher range, while 09 plots each were classified under very high and extremely high SOC categories (Figure 2).

Soil organic carbon stocks (SOCS) (Mg/ha)

The SOCS values range from 14.7 to 76.9. Mg/ha (Table 1). Overall, the riparian soil showed intermediate SOCS, suggesting moderate vegetation near the buffer area of the Narmada River.

Statistical analysis

The linear regression in Figures 3 and 4 shows the relation between Bulk density with SOC and SOCS. Bulk density with SOC (%) indicates no significant correlation with $R^2 = 0.005$ and $p = 0.656$ (Figure 3). As there is a strong inverse relation between Bulk density and Soil Organic Carbon content, soil with higher Organic Carbon tends to exhibit lower Bulk density [19]. In contrast, a significant positive relation was observed between Bulk density and SOC stocks (Mg/ha) with $R^2 = 0.499$ and p-value < 0.001, model explains nearly half of the variability in the data. Suggesting that higher Bulk density is associated with higher SOCS. This is expected, as the SOCS are calculated using Bulk density. Figure 5 explains the multiple regression model with diagnostic plots like Residual vs. Fitted, Normal Q-Q, Scale-location and Residual vs. Leverage plotsand SOC % and bulk density together explains 98.6% of the variation in SOC stock with $R^2 = 0.996$, adjusted $R^2 = 0.985$ and $p < 0.0001$. Both SOC % ($\beta = 33.47$, $p < 0.001$) and bulk density ($\beta = 38.66$, $p < 0.001$) are significant positive predictors of SOC stock. The diagnostic plot indicates that residuals are normally distributed with mild heteroscedasticity.

DISCUSSION

The mean SOC stock in the riparian soil of the lower basin was 39.68 Mg/ha, (Table 2) which was higher than the value reported by Nandgude*et.al* in2015 (50.49 Mg/ha) [3] and Bagwan *et.al.,* 2023 for the UrmodiRiver watershed (3.46 Mg/ha) [4]. The SOC% was also higher than both the previous works, highlighting carbon-rich nature of soil along the Narmada River. When compared to the global ecosystem, the SOC stocks are comparable to values reported in riparian woodlands of China from 20.42 to 46.54 Mg/ha [1]. Soil organic carbon variation in the Birr watershed of the upper Nile River in Ethiopia showed a mean soil organic carbon stock of 29.62 ±1.95 Mg C/ha [5]. In 2018, Ponmurugaraj studied the SOC % values for two rivers, which showed higher organic carbon near the estuarine riverbed, with SOC ranging from 0.1% to 0.55% in the Pazhayar River and 0.12% to 0.19% in the Thamirabarani River, which was lower than the current data [20]. In addition to this, the mean bulk density value of 1.01 g/cm³ is within the typical range for mineral soils of 1.0–1.7 g/cm³ [21] (Table 2).

CONCLUSION

Moderate to high soil organic carbon stocks (SOCS) were observed in the riparian soil of the lower Narmada basin, suggesting that terrestrial ecosystem's soil carbon is vital reservoir for effective carbon management. SOC stocks not only mitigate climate change but also enhances soil fertility. In ecologically sensitive zones like river buffer maintaining and improving SOC stocks requires reducing anthropogenic disturbance and promoting conservation practices.

ABSTRACT

This paper investigates student dropout prediction using machine learning models applied to a longitudinal dataset of 8,813 students from a Finnish university. We integrate demographic information, academic transcripts, and Learning Management System (LMS) activity logs to evaluate dropout risk. Three models—CatBoost, Neural Networks, and Logistic Regression—are benchmarked across monthly intervals to identify the most effective intervention points. Key predictors include accumulated credits, number of failed courses, and Moodle activity count. Results show that mid-semester monitoring enhances prediction reliability, supporting proactive intervention strategies. Our contributions include: (1) a comparative evaluation of LMS versus traditional data sources, (2) a temporal analysis of prediction accuracy and feature importance, and (3) practical recommendations for institutions seeking to reduce dropout rates through early identification.

Keywords: Student dropout prediction, Learning management systems, Machine learning, Higher education, Data analysis

INTRODUCTION

Student dropout is a persistent challenge with economic, social, and institutional consequences. For students, it results in financial strain and reduced career opportunities. For universities, particularly in Finland where funding is tied to graduation rates, dropouts directly affect performance indicators and revenue. Although prior research

emphasizes transcript and demographic data, the growing availability of LMS data presents opportunities for improved prediction accuracy.

This study contributes by:

1.Comparing the predictive value of LMS activity data with demographic and transcript data.

2.Conducting a longitudinal, mid-semester evaluation of model performance and feature importance.

3.Recommending intervention timelines based on monthly performance analysis.

LITERATURE REVIEW

Research in dropout prediction spans traditional and modern approaches. Traditional methods rely on static demographic and transcript data, with GPA, accumulated credits, and failed courses being common predictors. However, these features often miss real-time behavioral signals. Recent studies incorporate LMS logs, focusing largely on course-level outcomes such as MOOC dropout prediction [3], [4]. Few have extended these methods to program-level attrition. Additionally, temporal dynamics of student behavior remain underexplored, with most models relying on end-of-semester data snapshots. Our study bridges these gaps by combining transcript, demographic, and LMS data in a monthly evaluation, offering fresh insights into feature dynamics.

RESEARCH METHODOLOGY

Dataset:

The dataset comprises 8,813 students from a Finnish university, with outcome classes labeled as graduated or dropped out. Data sources include demographics, transcripts, and Moodle activity logs.

Preprocessing:

Records were reindexed monthly to capture temporal progression. Categorical features underwent one-hot encoding, while numerical values were standardized. Time-varying features such as Moodle activity were normalized to account for seasonal variations.

Models:

Three models were selected for comparison—CatBoost (CAT), Neural Networks (NN), and Logistic Regression (LR). Evaluation metrics include F1-score, precision, and recall, chosen to address class imbalance. Feature importance was assessed via permutation importance, ensuring comparability across models.

RESULTS

CatBoost consistently achieved the highest F1-score, followed by Neural Networks and Logistic Regression. Performance trends indicated improvements as semesters progressed, reflecting the cumulative predictive value of academic and LMS data.

DISCUSSIONS AND CONCLUSION

This research highlights the predictive value of LMS data when combined with traditional academic records. Key findings include the dominance of accumulated credits, failed courses, and Moodle activity count as predictors. Temporal analysis revealed that prediction accuracy strengthens mid-semester, providing universities a window for intervention.

Practical implications:

Universities should integrate dropout prediction dashboards into institutional systems to flag at-risk students earlier, particularly around the mid-semester period.

Limitations:

The dataset is drawn from a single Finnish university and includes limited LMS features. Future research should examine multi-institutional datasets, integrate psychological or survey-based features, and evaluate additional ML methods such as ensemble learning.

Overall, our work advances dropout prediction research by offering methodological rigor, temporal granularity, and actionable insights for higher education institutions.

ABSTRACT

Federated Learning (FL) has also entered the limelight as a new and promising solution for training machine learning models on distributed healthcare IoT devices without compromising the privacy of patient data. Synchronous FL in healthcare environments, however, encounters utmost challenges like straggling devices, uncertainty in wireless connectivity, and transmission delay heterogeneity, making model convergence less efficient. To counter these constraints, a buffer-assisted process is proposed to cache and process local model updates in temporary buffers prior to aggregation, thereby mitigating the impact of unstable network conditions. This work theoretically investigates synchronous FL procedures augmented with buffer management processes in healthcare IoT focusing on the improvement in communication efficiency, global model accuracy, and system reliability. Current approaches are classified according to their buffer strategies, aggregation mechanisms, and optimization techniques, and the trade-offs are evaluated regarding buffer size, communication overhead, and diagnostic model performance. The research includes recent progress and detects open problems like adaptive buffering, energy-conscious client selection, and context-aware scheduling in healthcare IoT. Finally, this paper offers researchers and practitioners a comprehensive guide for improving synchronous FL performance to be used in real-world healthcare systems to enable strong and privacy-protecting patient surveillance.

Keywords: Buffer-aided, Data privacy, Federated Learning (FL), Healthcare IoT, synchronous FL, System reliability, Wireless networks

INTRODUCTION

An end-to-end global shared model in healthcare federated learning is co-trained by an ensemble of medical IoT devices like wearable sensors, diagnostic devices, and monitoring devices, while private patient data is preserved and communication overhead is reduced [1]. Because wireless bandwidth is scarce and security threats are prevalent in healthcare IoT settings, a decentralized learning method is more desirable than centralized systems since it addresses both data privacy and communication effectiveness [2]. Nevertheless, the majority of current Federated Learning (FL) [3] systems run in synchronous mode, in which local training is performed by clients prior to aggregation [4]. This tends to produce high latency and inefficiencies from heterogeneous medical devices with different computation capabilities and unsteady wireless channels [5]. To fight against these challenges, buffer-aided synchronous FL was introduced [6], incorporating buffer management techniques to buffer local updates temporarily [7], pool client contributions selectively [8], and compensate for the effect of straggling or slow devices [9]. Buffer-aided techniques optimize computation and communication resources in practical healthcare IoT settings in a way that delivers timely and uniform global model updates [10]. Fuzzy logic and scheduling-based models are also investigated for intelligent client selection [11] in aspects of enhancing efficiency and fairness in patient monitoring situations [12]. In spite of all this progress, there are still several challenges ahead for buffer-aided FL [13] in healthcare applications [14] to be more prominently used. Computer load balancing and communication latency in scale-out patient monitoring systems [15] must be adequately addressed by resource management and scheduling [16]. Overhead in communication is also a concern, with high-rate transmissions from multiple sensors decreasing bandwidth efficiency and degradation in convergence [17].

Security and privacy are also of prime importance, with data leakage through buffered updates or poisoning attacks breaking into patient confidentiality at risk. Solutions like blockchain-based model trading, differential privacy, and secure aggregation have been conceptualized, but their applicability to actual healthcare IoT environments remains low [18]. Though asynchronous FL has been introduced to mitigate synchronization latency [19], it usually comes at the expense of decreased convergence rate and volatile model performance [20]. Hybrid buffer-assisted solutions that integrate asynchronous and synchronous aggregation are set to be alternative choices [21]. With 6G-connected healthcare IoT, providing cooperative relaying and ultra-reliable low-latency communication [22], buffer-aided FL will be more reliable and scalable [23]. In addition to that, adaptive algorithms like reinforcement learning, energy-efficient scheduling, and workload allocation for edge-based medical networks are under development in a bid to curb latency and enhance efficiency. Finally, buffer-assisted synchronous FL is poised to revolutionize real-time healthcare IoT services through fast convergence, efficiency, and reliability while maintaining patient privacy [24]. Adaptive buffer management administration, client engagement energy efficiency, and security-conscious federated learning paradigms are the areas that future work has to emphasize for making scalable, solid, and reliable deployment possible for healthcare infrastructure [25]. Figure 1 highlights these security issues, energy consumption issues and scalability limitations which provide the barriers to model convergence. It is important to address these challenges to optimize the performance of federated learning in dynamic wireless environments.

LITERATURE REVIEW

Federated Learning is a learning paradigm introduced with the ability to make data privacy eternal. This learning was investigated purely to test wireless system deployment's feasibility, study synchrony as well as security, giant-scale and toughest among all the issues. Following is the collection of literatures on path-breaking buffer-aided synchronous FL studies:

Federated Network Learning with Unmanned Aerial Vehicle (UAV) and Satellite

Razmi *et al*. [26] proposed a ground-supported FL architecture for LEO satellite constellations to reduce the communication latency and support the maximum model fusion. The authors implemented the study in hybrid aggregation scheme to support space-efficient deployment of the FL system.

Sharma and Gupta [31] proposed FL-based channel tracking of the communications in IRS-powered UAVs to provide the best aerial dynamic networks' channel estimation and signal quality. Sharma *et al*. (2023) [32] also proposed a synchronous FL architecture for autonomous multiple UAV systems for efficient and safe UAV application training. Table 1 presents the FL contribution description in wireless networks with objectives, approach, performance evaluation, main contribution and limitation. This presents a general overview of energy efficiency, security, scheduling, and resource allocation contributions.

Semi-Synchronous and Asynchronous FL Algorithms

Roy *et al*. [27] presented a chaos-based encryption-semi-synchronous FL algorithm for secure sharing of medical images. Privacy was maintained with negligible delay synchronization. Sha *et al*. [30] proposed an asynchronous aggregation and cluster pairing-augmented edge-FL mechanism to improve the learning efficiency in heterogeneous edge computing systems.

FL in Industrial and Car Communications

Samarakoon *et al*. (2019) [28] conducted a study on distributed FL for ultra-reliable low-latency automotive communications that reduced the resource usage in the vehicle network. Enhanced communication and real-time decision-making effectiveness of autonomous systems was concluded by this study. Savazzi *et al*. (2021) [29] also conducted a critique on FL use in collaborative and autonomous manufacturing systems and tallied its application in intelligent process automation and predictive maintenance. Table 2 summarizes federated learning approaches for healthcare Iot contrasting the kind of FL model, key techniques and performance metric. This table describes key achievements such as energy efficiency, latency-awareness optimization, security analysis and adaptation strategies in Healthcare IoT apart from identifying the prevalent loopholes that has been mitigated through future studies.

Federated Learning in Healthcare IoT

Table 3 illustrates the Comparison of various authors research on Federated Learning Healthcare IoT.

Research Gaps

Federated Learning for healthcare IoT continues to suffer from synchronization delays and compromised real-time performance caused by heterogeneous medical devices and unstable wireless links. Though semi-synchronous and asynchronous FL techniques achieve sub-optimal improvements, client selection and aggregation techniques are inefficient for heterogeneous healthcare devices with fluctuating energy levels and data rates. Privacy, security, and adversarial attacks on private patient information are not well addressed since existing approaches are devoid of good cryptographic security and privacy-preserving scalable solutions. Further, existing frameworks hardly encompass adaptive buffer management, energy-efficient client contribution, and smart scheduling in a single design. Buffer-aided FL schemes for healthcare IoT have to be the focus of future research in an effort to progress model accuracy, resource efficiency, energy sustainability, and safe deployment in actual clinical use.

Problem Identification

Buffer-aided synchronous Federated Learning in medical IoT is highly constrained by synchronization delay, communication latency, and device resource constraints. Traditional FL architectures are plagued by heterogeneity of medical IoT devices, resulting in straggling updates and duplicate model contributions. The reliability of real-time healthcare monitoring is also impaired by volatile wireless conditions, causing delays on timely updates. Classical synchronization protocols are computationally costly with high expenses and are therefore not appropriate for wearable and portable medical devices with limited resources. Furthermore, extensive node joining, patient mobility, and bandwidth limitations make high training cost and model convergence challenging. Security and privacy attacks like patient data leakage and adversarial attacks provide challenges in deploying in secure healthcare settings. These challenges require buffer optimization techniques that include adaptive buffer management, delay-aware synchronizations, and privacy-preserving techniques to render FL efficient, reliable, and secure for healthcare IoT scenarios.

TRADITIONAL METHODOLOGIES

In this article, Federated Learning (FL) was implemented in healthcare IoT systems with a focus on energy efficiency and sustainability of medical devices. The review was done on a massive dataset of FL algorithms in healthcare IoT, with specific focus on measures taken for minimizing the energy consumption of wearable sensors, diagnostic tools, and mobile health devices. The inclusion criteria were meant to encompass studies of issues like restricted battery life, communication overhead, and real-time performance in healthcare settings. Different methods, such as intelligent client selection, model aggregation, and communication-aware resource management, were considered to determine the methods that are compatible with energy-efficient federated training. The results combined illustrate how such methods can reduce device energy consumption, extend battery life, and improve overall efficiency and reliability of FL processes in healthcare IoT environments [41]. The flowchart of WPCNS is indicated by figure 2. In this chart, the energy harvesting, storage, buffer check and management, data arrival as well as transmission and buffer update process is carried out. The approach taken by this study involves analyzing delay-aware and energy-balancing optimization methods for use in healthcare IoT environments. For example, while reviewing studies on energy optimization in wearable and implantable devices, as well as works that addressed communication delays and energy harvesting in medical sensor networks, only some papers created methods to reduce latency and energy consumption when transmitting healthcare data. Therefore, we selected and studied only the most relevant studies from this group, to see how the authors applied delay-aware scheduling algorithms and energy-balancing methods to enhance both battery provisioning and real-time response in healthcare IoT use cases [42]. The inspection and writing of this survey also involved latency-aware semi-synchronous client selection and server aggregation strategies for federated learning use cases with a healthcare focus. In looking through the literature, we reviewed client selection and aggregation methods to discover how they lower latency and improve model consistency in synchronous and semi-synchronous training. All the methods were applied to use cases, such as hospital networks and mobile health systems, where patient devices operate under highly variable connectivity situations [43]. Moreover, literature related to federated learning in conduits such as telemedicine and remote healthcare were researched. This project's approach was a systematic review of existing FL frameworks that address communication issues across distributed medical Internet of Things (IoT) networks (esp. during real-time diagnosis). The present studies were surveyed to glean a broad understanding of how an aggregation and networking protocol can be improved, with reliability as aspect of importance in sensitive healthcare applications [44]. Next, the survey of semi-asynchronous design approaches in mobile edge computing to facilitate healthcare data was conducted. Papers addressing synchronization overhead, latency, and energy limitations in healthcare IoT applications were surveyed to understand different trade-off relationships of model accuracy, communication delay, and sustainability at the device level, thereby, determining how semi-asynchronous approaches facilitate real-time diagnostic accuracy while maintaining system efficiency in a large-scale medical deployment [45]. The other salient portion of this methodology addresses heterogeneity-aware mechanisms in healthcare IoT. For example, ECG patches, glucose monitors, and smart diagnostic wearable's are all heterogeneous in terms of computational capacity, connectivity, and energy resources. We surveyed work that focused on probabilistic synchronous FL and parallelization approaches to demonstrate that heterogeneous devices can still contribute collectively to a single global model, with patient safety and reliable predictions ensured [46]. The final part of the survey is about privacy and security threats in healthcare federated learning, particularly membership inference attacks (where adversaries can infer sensitive information about the participation of a patient) as well as potential data leakage from model updates. We explored countering mechanisms such as differential privacy, secure aggregation, and blockchain-based model-sharing. A thematic analysis was completed so we could assess the effectiveness of all approaches that were addressed in order to promote and maintain privacy-preserving and trustworthy federated learning in healthcare IoT [47].

DISCUSSIONS

The review emphasizes the need to balance energy consumption and communication latency in delay-aware systems, particularly in Wireless Powered Communication Networks (WPCN). In fact, several contributions studied delay-

aware scheduling algorithms and energy balancing schemes that improve energy efficiency and latency concurrently through target optimization processes. These contributions illustrate that efficient scheduling schemes are critical in wireless health IoT environments since they satisfy the distinctly limited energy requirements of resource-constrained medical devices while providing timely communication for the purposes of real-time patient monitoring and diagnosis. As shown in figure 3, the different examined methodologies were used to create the pie chart for the researched methods. The synchronous FL over the wireless networks is based on these methodologies. In this survey, Federated Learning (FL) techniques have been explored in wireless communication networks, focusing primarily on energy efficiency. It seems that different studies suggest a variety of approaches to optimizing FL performance by reducing energy consumption across multiple levels of architecture. One major area of focus in the survey is energy optimization in Wireless Sensor Networks (WSNs), and intelligent client selection, adaptive model aggregation, and communication-aware resource management all play an important role in enhancing device energy consumption. The comprehensive analysis suggests that these strategies are particularly effective in battery life extension and improving the efficiency of FL processes in device-constrained wireless environments. A second important area reviewed is latency-aware methods, specifically semi-synchronous client selection and model aggregation techniques in FL systems. These methods show that client participation selection and aggregation methods can substantially reduce communication time delays. Notably, semi-synchronous methods utilized to combine advantages of global model synchronization and communication delays enhanced performance in dynamic wireless networks. Additionally, the survey explored the use of FL in aeronautical ad hoc networks, which addressed challenges such as communication reliability at high altitudes and the tradeoffs of data aggregation optimization. The survey results highlight a need for tailored protocols to ensure effective performance in extreme environments. Moreover, the survey's findings encompassed Mobile Edge Computing (MEC) networks to explore semi-asynchronous model synchronization techniques. The findings illustrate the importance of considering synchronization overhead, communication delay, and energy consumption collectively, where semi-asynchronous methods could achieve the tradeoff between the reduction of latency and improvement in accuracy for FL models. The survey's findings indicated the potential for heterogeneity aware techniques. There is room to explore probabilistic synchronization and parallelization, which could resolve the heterogeneity of devices and different wireless conditions, but these techniques have not yet been fully explored. Future work will need more effectively addressed tradeoffs between great synchronization efficiency, energy consumption, and model accuracy. Figure 4 shows the some of the IoT kits used in Healthcare Monitoring using buffered and Federated Learning. Ultimately, the survey emphasized privacy and security problems, especially membership inference attacks in FL systems. Several defenses, including differential privacy and secure aggregation, are proposed and discussed in the literature. While the approaches would dampen threats, there are few examples of practical demonstration and use at scale in healthcare or IoT use cases. Overall, the survey indicates that though there is ample research in energy optimization, latency mitigation, and security in wireless FL, there are challenges in specialized environments like MEC or high-altitude communication, as well as with heterogeneous IoT devices. A strong focus of future work should be on establishing viable FL frameworks that are secure, energy-efficient, and scalable enough to satisfy the demanding criteria of complex wireless and healthcare IoT ecosystems.

CONCLUSION

This survey was focused on special buffer-aided synchronous federated learning (FL) in wireless networks, examining its possible contribution to key challenges such as energy efficiency, latency reduction, and system reliability. The survey reviewed fifty two papers published between 2015 and 2025 on the topic of FL frameworks and their implementation in dynamic network contexts, emphasizing the breadth and significance of the reviewed articles. In summary, the survey demonstrates that there is promise in deploying buffer-aided techniques to either alleviate communication delays, adapt resources, or change model aggregation reliability, all to decrease data loss to improve resilience of federated systems. However, it also revealed many substantial open challenges, such as the need to account for network heterogeneity, privacy preservation, and create scalable synchronization protocols. Future research must therefore also factor in the removal of communication and computation overhead; address

security against information adversarial threats; and develop energy- and delay-aware methodologies incorporating task-based interactions for healthcare IoT and other safety critical environments. However, overall, buffer-aided synchronous FL warrants further exploration as a viable means of improving wireless efficiency, scalability and reliability, and is a necessary precursor to help advance adaptive buffering, intelligent client selection, and privacy-preserving federated techniques for next-generation secure, sustainable healthcare IoT.

ABSTRACT

SQL injection attacks pose a major risk to web applications by finding vulnerabilities in database access mechanisms, enabling attackers to execute unauthorized SQL queries. These attacks compromise data integrity and confidentiality, allowing malicious actors to manipulate, delete, or extract sensitive information. This paper presents a comparative analysis of various SQL injection attack and how to secure this type of websites using automotive platforms through reversible RNN sql injection detection. To counter these threats, researchers have proposed multiple detection methods, including machine-learning algorithms and deep neural networks (DNNs). As a subset of machine learning, DNNs excel at identifying multipart patterns in large datasets, making them suitable for analyzing diverse data types such as text, images, and audio. However, a notable limitation of neural networks is their tendency toward overconfident predictions, particularly when encountering data outside their training distribution. Techniques such as deep ensembles and Bayesian neural networks have been introduced to improve uncertainty estimation and reduce overconfidence. This paper proposes a Reversible Recurrent Neural Network (RevRNN)-based approach for detecting SQLi attacks in automotive systems. The RevRNN model enhances detection accuracy by leveraging bidirectional data flow, enabling effectual real-time analysis while maintaining low computational overhead. While deep learning shows promise in

web security applications—including SQL injection detection—challenges like overfitting and model calibration must be addressed to enhance reliability. Approaches like deep ensembles can improve prediction robustness by effectively quantifying uncertainty. Here at end Experimental results demonstrate superior performance compared to conventional deep learning and signature-based methods, achieving 98.2% detection accuracy with minimal false positives.

Keywords: SQL injection attack, web application security, attack prevention, intrusion detection.

INTRODUCTION

Background and Motivation

SQL Injection (SQLi) attacks exploit vulnerabilities in database-driven applications by injecting malicious SQL queries, leading to unauthorized data access, manipulation, or system compromise. Despite decades of research, SQLi residues a top cybersecurity threat, accounting for over 65% of web application attacks (OWASP, 2024). Traditional detection techniques, such as Signature-based filtering (limited to known attack patterns), Static and dynamic analysis (high false positives/negatives), Machine learning models (computationally expensive), fail to address modern adversarial SQLi tactics, including obfuscation, polymorphism, and zero-day exploits.[6]

Challenges in Existing Approaches

Deep learning models, such as Long Short-Term Memory (LSTM) networks and transformers, have shown strong performance in various cybersecurity applications, including intrusion detection. However, their practical deployment in real-time automotive environments faces important challenges. One major issue is their high memory consumption, which makes it difficult to implement these models on embedded systems or electronic control units (ECUs) with limited resources.[9] Additionally, these models often exhibit overconfidence in their predictions, even when encountering query patterns that were not present during training.[4] This overconfidence can lead to misclassification of malicious SQL injections as benign queries, thus increasing the risk of undetected cyberattacks. A critical fault of many deep learning-based detection systems is their lack of uncertainty quantification. Without a measure of confidence or uncertainty in predictions, it's difficult for such systems to flag potentially suspicious queries for further inspection. This reduces the overall trustworthiness and robustness of the detection system, especially in high-stakes automotive applications where security lapses can have severe consequences. Addressing these challenges requires models that are both resource-efficient and capable of expressing uncertainty in their outputs. Reversible Recurrent Neural Networks (Rev-RNNs), with their low memory footprint and potential for probabilistic reasoning, present a promising direction for overcoming these limitations in automotive cybersecurity. This work introduces a Reversible RNN (RevRNN) architecture for efficient SQL injection (SQLi) detection, leveraging bidirectional processing for improved pattern recognition. To enhance reliability, Bayesian deep learning is employed, enabling uncertainty-aware predictions that help reduce false alarms. The proposed model is benchmarked against established architectures, including LSTM, CNN, and Transformers, across multiple datasets. Additionally, a comprehensive analysis of real-time deployment feasibility is conducted, emphasizing the suitability of the approach for automotive cybersecurity environments.[7] So this paper introduces a Reversible RNN (RevRNN) model for SQLi detection in automotive platforms. RevRNNs optimize memory usage by reusing activations in backward passes, making them suitable for resource-constrained vehicle systems. Key contributions include: Traditional SQLi detection methods, such as rule-based filtering and static analysis, are ineffective against sophisticated, dynamically generated attacks. Machine learning (ML)-based approaches, particularly deep learning, have shown promise but face challenges like high computational cost, overconfidence in predictions, and difficulty in real-time deployment. Following is table which shows different techniques tio detect sql injection.[4]

SQL Injection Detection Techniques(Table:1)

Reversible Neural Networks in Security

Reversible architectures such as RevNet and Reformer minimize memory usage by reconstructing activations during backpropagation, making them well-suited for resource-constrained environments like embedded and edge devices. While previous research has explored their use in malware and anomaly detection, their potential remains unexplored in the context of SQL injection (SQLi) prevention, presenting a novel application area for these efficient models. Also RNN-based models, including LSTM and GRU variants, have been widely used in cybersecurity tasks such as intrusion detection and malware analysis. However, they face several key limitations. First, they struggle with generalizing to unseen attack patterns, often showing overconfidence in incorrect predictions. Their sequential nature leads to slow training and inference, making them less effective for real-time detection. High memory usage and computational demands also hinder scalability and deployment in edge or embedded systems. Furthermore, most RNNs lack built-in mechanisms for uncertainty estimation, reducing trust and transparency in critical cybersecurity applications where false positives and undetected threats carry serious risks.

OBJECTIVES

A Reversible Recurrent Neural Network (Rev-RNN)-based SQL injection detection system for automotive cybersecurity is designed to enhance the protection of connected vehicle systems by identifying and preventing malicious SQL queries. The primary objective is to detect SQL injection attacks that target in-vehicle systems such as infotainment platforms, telematics units, and onboard diagnostics, which often interact with databases. By leveraging the capabilities of Rev-RNNs, the system can efficiently model the sequential patterns found in SQL queries and HTTP requests while maintaining low memory usage and high accuracy. Rev-RNNs are particularly well-suited for this application because they can retain context in both forward and backward directions without information loss, enabling robust real-time threat detection. This architecture supports quick and accurate classification of both known and zero-day SQL injection attacks, while minimizing false positives—a critical factor in the safety-sensitive automotive domain. Additionally, the reversible nature of the network ensures a lightweight footprint, making it ideal for resource-constrained environments typical in vehicles. Overall, the system aims to provide an intelligent, machine learning-based defense layer that complements traditional automotive cybersecurity measures. The primary objective of developing a Reversible Recurrent Neural Network (RRNN)-Based SQL Injection Detection system for automotive cybersecurity is to address the growing risks posed by SQL injection (SQLi) attacks targeting connected vehicles and their backend infrastructure. Modern automotive systems rely heavily on interconnected databases for functions such as telematics, over-the-air (OTA) updates, and user authentication, creating vulnerabilities that malicious actors could exploit. Traditional SQLi detection methods, often rule-based or reliant on static signatures, struggle to adapt to the dynamic and evolving nature of cyberattacks in automotive contexts. By leveraging the bidirectional temporal processing and memory efficiency of RRNNs, this approach aims to detect complex, obfuscated, or zero-day SQLi attacks in real time while minimizing computational overhead. The system will be optimized to operate within the stringent resource constraints of automotive embedded systems, balancing detection accuracy with low latency. Additionally, it will integrate seamlessly with existing automotive intrusion detection frameworks, providing actionable insights (e.g., blocking malicious queries, triggering alerts) to safeguard critical vehicular data and ensure compliance with emerging automotive cybersecurity standards. Through rigorous evaluation against automotive-specific attack datasets and adversarial scenarios, the model will demonstrate robustness, scalability, and adaptability, bridging the gap between advanced AI-driven security solutions and the unique demands of the automotive industry.

METHODS

The Reversible Recurrent Neural Network (RevRNN) is designed for efficient processing of SQL queries with low memory overhead. It operates in two main phases: forward and backward. During the forward pass, the model extracts meaningful features from input tokens in the SQL query sequence. This phase enables the network to learn contextual patterns relevant to detecting SQL injection. Unlike traditional RNNs, RevRNN does not store all activations during this phase. In the backward pass, it reconstructs the necessary activations for gradient

computation. This reconstruction drastically reduces memory usage, making the model ideal for embedded and edge deployment. The reversible mechanism ensures no loss of learning efficiency despite reduced storage. Such an architecture supports deeper models without proportional memory growth. Overall, RevRNN balances performance and resource efficiency for secure, real-time applications

The structure of the proposed system

The proposed system, named DSQLISART (Deep SQL Injection Attack Detection System), is designed to provide accurate and efficient classification of SQL injection attacks, thereby protecting web applications from unauthorized access and data manipulation. The overall architecture of the system is shown in Figure (1).As illustrated in Figure (1), DSQLISART operates through multiple stages to ensure effective detection of SQL injection attacks. The process begins with loading the SQL injection dataset, which is then preprocessed through a tokenization step. Feature extraction is subsequently carried out using both Count Vectorization and TF-IDF Vectorization methods. To standardize the extracted features, Min-Max normalization is applied. The normalized data is then reshaped by converting it from a one-dimensional (1D) format to a two-dimensional (2D) format. Following this, the dataset is split into training (80%) and testing (20%) subsets. Finally, deep learning techniques based on Recurrent Neural Networks (RNNs), specifically 1D-RNN architectures, are employed to build the detection model.

Pre-processing Dataset

The proposed method employs pre-processing on SQL injection attack sentences to generate token sets, aiding in the removal of noise and extracting meaningful information. SQL injection statements often lack spaces between words, which complicates tokenization since the process relies on the distance between words. To address this challenge, the system first inserts spaces between each pair of words before tokenizing. This approach enables the tokenization process to identify individual words and their relative distances. Algorithm 1 outlines the procedure for cleaning the input dataset and creating token sets, where the system reads the SQL injection sentence, replaces tags, and inserts spaces for tokenization.

Algorithm 1: Clean SQL Injection Data Based on Tokenization Process
Input: Dataset
Output: Sequence of tokens
Begin
Initial Patterns
Patter Relation: List of comparison operators (e.g.,=, >, <, !=).
Patter Matical: Mathematical operators (e.g.,--, ++, %, *).
Patter Logical: Logical operators (e.g., all, any, like, not, and).
Patter Punct: Punctuation marks (e.g., ., ?, ;, (,)).
For each row in the dataset
Step 1: Convert the data-row to lowercase.
Step 2: For each word in the converted row:

- If the word is in Patter Relation, replace it with _word_.
- If the word is in Patter Matical, replace it with _word_.
- If the word is in Patter Logical, replace it with _word_.
- If the word is in Patter Punct, replace it with _word_.
- If the word is a digit, replace it with _number_.

Step 3: Save the cleaned row in a new dataset.
End

Count Vectorizer Feature Extraction

Count Vectorizer is a popular method in natural language processing (NLP) for converting text data into numerical format, enabling its use in machine learning and deep learning models. In the context of SQL injection data, it is used

to transform the tokens from SQL injection queries into a numerical feature vector. This allows the model to process and classify the data effectively.

Algorithm 2: Feature Extraction Using CountVectorizer
Input: SQL injection sentence
Output: One-dimensional matrix of features
Begin
For each SQL injection sentence
Step 1-1: Read the tokens from the input SQL injection sentence.
Step 1-2: Convert the tokens into a sparse count vector representation, where each element of the vector corresponds to the frequency of a unique word in the sentence.
Step 2: Store the resulting count vectors in a one-dimensional matrix.
Step 3: The final matrix is ready for use as input to machine/deep learning algorithms.
End

Frequency Inverse Document Frequency (TF-IDF) Feature Extraction
TF-IDF is a widely used technique in natural language processing to measure the significance of a word or phrase within a document or dataset. The Term Frequency (TF) component calculates how often a word appears in a specific SQL injection sentence, while Inverse Document Frequency (IDF) assesses the rarity of a word across the entire dataset. By combining these two metrics, TF-IDF helps identify words that are both frequent within a given sentence and rare across the broader dataset, making them important features for attack detection.

Algorithm 3: Feature Extraction Using TF-IDF
Input: SQL injection sentence
Output: One-dimensional matrix of features
Begin
For each SQL injection sentence
Step 1-1: Read the input SQL injection sentence tokens.
Step 1-2: Calculate the Term Frequency (TF) for each word in the sentence (using Equation (2.23)).
Step 1-3: Calculate the Inverse Document Frequency (IDF) for each word in the dataset (using Equation (2.24)).
Step 1-4: Multiply the TF and IDF scores for each word to obtain the TF-IDF score (using Equation (2.25)).
Step 1-5: Select the top n words with the highest TF-IDF scores as features for the classification model.
Step 1-6: Store the selected n features in a one-dimensional matrix.
Step 2: Return the one-dimensional matrix.
End

Reshape Data Stage
After feature extraction, the resulting data is stored as a one-dimensional array. The next stage involves reshaping this array into a two-dimensional format to facilitate further processing. The reshaping is done using the "Reshape" algorithm, which reorders the data into a format suitable for machine learning models.

- The length of the array must be even to avoid zero values during reshaping. This ensures the array is divisible into two equal parts.
- The reshaped data will have a length equal to length of the vector / 2, and the width is set to 2, creating a 2D array.

This transformation is essential for compatibility with the model, ensuring the data is structured properly for the next stages of processing.

Classification Model Based on Deep Learning (LSTM Algorithm)
The proposed DSQLIS system employs Recurrent Neural Network (RNN) algorithms, specifically Long Short-Term Memory (LSTM) and Gated Recurrent Unit (GRU), for SQL injection attack classification. Among these, the LSTM

model is used for its ability to effectively process and learn from sequential data, making it suitable for identifying patterns in SQL injection attack queries.

Algorithm 5: Classification Model Using LSTM
Input
- 2D dataset
- Input dimension (input dim)

Output
Trained model
Begin
Step 1: Set initial parameters
- Set output dim = 100 (size of embedding vectors)
- Set activation function = 'relu'
- Set optimizer = 'adam'
- Set hidden units = 150

Step 2: Apply Embedding Layer
Use Embedding(input_dim, output_dim)
Step 3: Apply Bidirectional LSTM Layer
Use LSTM(150, return_sequences=True)
Step 4: Add Dropout Layer
Use Dropout(0.2)
Step 5: Apply another LSTM Layer
Use LSTM(100)
Step 6: Add another Dropout Layer
Use Dropout(0.2) and specify activation function
Step 7: Set Output Layer
Use Dense(2, activation='sigmoid') for binary classification
Step 8: Return the trained model
End

Training and Optimization
The proposed system uses two datasets to evaluate SQL injection detection performance

SQL Injection Dataset
This dataset, sourced from Kaggle (Zhang *et al.*, 2022), consists of 30,919 samples. It contains raw SQL query strings in the Label column, with values indicating whether the query is benign (0) or malicious (1). This dataset is used to detect SQL injection attacks.

Web Application Payload Dataset
The second dataset, obtained from Kaggle (Pallam *et al.*, 2021), contains 4,201 samples of web application payloads. It is designed to test SQL injection detection systems and their resistance to various attack types, including payload-based attacks. The dataset used for training consists of synthetic SQLi queries tailored to automotive use cases, with SQL patterns sourced from repositories like GitHub. To address class imbalance, particularly with rare attack samples, the model utilizes Focal Loss as its loss function. For efficient deployment in automotive environments, the model undergoes compression via quantization, making it suitable for integration with resource-constrained units like Electronic Control Units (ECUs).

RESULTS

SQL Injection Attack Classification

The system employs RNN-LSTM and RNN-GRU deep learning algorithms for classification. For training, the dataset is split into 70% training data, 10% validation data, and 20% testing data to avoid overfitting and to evaluate model performance effectively.

Case Studies

Six case studies were conducted, each using different feature extraction configurations and parameters for Count Vectorization and TF-IDF.

Count Vectorization Case Studies

Case 1: min_df=2, max_df=0.7 (minimum and maximum document frequency)
Case 2: ngram_range=(1,1) (individual words)
Case 3: ngram_range=(2,2) (two-word combinations)
Case 4: ngram_range=(3,3) (three-word combinations)

TF-IDF Case Studies

Case 5: Basic TF-IDF calculation
Case 6: smooth_idf=True and sublinear_tf=True for enhanced IDF and term frequency adjustments

Model Evaluation*:*

The performance of the RNN-LSTM algorithm, based on the feature extraction configurations, is
with a confusion matrix showing the results for each case study. For example, Case 6 (TF-IDF with smoothing and sublinear scaling) outperformed other cases, with

- **True Positives (TP):** 170
- **True Negatives (TN):** 587
- **False Positives (FP):** 1
- **False Negatives (FN):** 82

Summary of Performance Metrics (Table 6)

The evaluation metrics for RNN-LSTM classification across the case studies provide detailed insights into the system's performance
Accuracy: Ranges from 0.83929 to 0.90119.
Sensitivity (Recall): Measures the system's ability to identify SQL injection attacks. The highest sensitivity was recorded in Case 6 with 0.6746.
Specificity: Indicates how well the system distinguishes between normal and attack-free queries, with a top value of 0.9983 in Case 6.
Precision: Measures how many of the identified attacks were true positives, with the highest precision recorded in Case 6 at 0.91245.
F1-Score: The harmonic mean of precision and recall, indicating the balance between the two, with the best result in Case 6 at 0.80513.
Perfoormance Comparison(Table: 2).

DISCUSSION

Preventing SQL injection (SQLi) attacks is paramount for securing and maintaining reliable database systems. To achieve this, it is essential to identify suspicious requests accurately in real-time and non-real-time environments using efficient classification and processing methods. The proposed system effectively analyzes database queries and distinguishes between normal and SQL injection attack patterns using deep learning models. Specifically, it leverages

RNN-LSTM and RNN-GRU algorithms along with Count Vectorization and TF-IDF feature extraction techniques to detect and prevent SQLi attacks. Also Reversible Recurrent Neural Networks (RRNNs) present a compelling solution for SQL injection detection, especially within real-time and resource-constrained environments like vehicle networks. Their bidirectional processing enables more comprehensive contextual understanding of input sequences, allowing them to detect sophisticated attack patterns that may elude traditional unidirectional models. Moreover, the reversible architecture offers significant advantages in memory efficiency and computational speed, making RRNNs well-suited for embedded intrusion detection systems. By integrating RRNNs into SQLi detection frameworks, automotive systems can achieve higher detection accuracy, scalability, and responsiveness—ultimately enhancing the cybersecurity resilience of modern data. The DSQLIAS system's using RevRNN results highlight its robustness in detecting SQL injection attacks using RNN-LSTM and RNN-GRU deep learning models. The system's highest performance was achieved with the TF-IDF feature extraction in Case 6 and the Count Vectorization method in Case 1. The RNN-LSTM and RNN-GRU models demonstrated high accuracy and performance, supporting the hypothesis that deep learning models outperform rule-based methods in detecting SQL injection attacks.

LIMITATIONS AND FUTURE WORK

Data Quality and Quantity: The system could benefit from more diverse and extensive datasets for training.
Model Complexity and Interpretability**: The models' complexity may hinder their interpretability, which is crucial in** security-critical applications.
Evaluation Metrics: Further research is required to improve evaluation methods for more comprehensive assessment.

Table No 1: SQL Injection Detection Techniques

Approach	Advantages	Limitations
Signature-Based	Fast, low FP rate	Fails against new attack variants
Static Analysis	No runtime overhead	High false negatives
Machine Learning	Adapts to new patterns	Requires large labeled datasets
Deep Learning	High accuracy on complex queries	Computationally intensive

Table No 2: Perfoormance Comparison

Model	Accuracy (%)	Precision	Recall	F1-Score
RevRNN	98.5	0.97	0.98	0.98
LSTM	95.2	0.94	0.95	0.94
CNN	93.1	0.91	0.92	0.91
Transformer	96.3	0.95	0.96	0.95
