The results of this study show that traditional clinico-statistical indicators can be used to effectively model the early risk of Type 2 Diabetes Mellitus using a transparent and hybridizable machine learning platform that combines classical statistical models with advanced ensemble learning paradigms. The BMI was determined to be an always dependable predictor of diabetes onset in each of these models. The log-regression analysis showed that the risk of diabetes increased positively and steadily as body mass index (BMI) rose. The proportional hazard model by Cox confirmed this result, showing a positive correlation between body mass index and the risk of developing diabetes at an earlier age. Without regard to statistical assumptions, the congruence of the hazard and probability models supports the idea that BMI is a trustworthy precursor of diabetes onset. With XGBoost demonstrating the highest accuracy and AUC, machine learning models outperformed traditional log-regression. This occurred as a result of the boosting paradigm's nominal mathematical construction, which allowed for the regulated and dependable handling of non-linearities through the use of a regularised objective function to inform the additive combination of optimised decision trees used for prediction. Support Vector Machine's interpretability issues made it unfit for clinical usage, but its capacity to optimise margins on a transformed feature space allowed it to do well in discriminating. Compared to logistic regression, Random Forest performed somewhat better, but it was no match for XGBoost. By contributing features, the SHAP explainability evaluation enhanced interpretability. The results of the regression and survival analyses corroborated the dominance of body mass index (BMI), haemoglobin A1c (HbA1c), and fasting glucose over other variables in the SHAP value plots, which strengthened the internal consistency. It is possible that HbA1c has nonlinear connections that are not captured by linear models, as it had a substantial impact on machine learning models but no individual significance in regression analysis. The calibration plots showed a high degree of concordance between the anticipated and actual risks in XG Boost, which is in line with its therapeutic application. The study's limitations include a small sample size and no external validation. Despite these issues, the results demonstrate that XGBoost and explainable machine learning offer a reliable and understandable framework for predicting the likelihood of diabetes in its early stages, which lends credence to its possible use in preventive clinical care.

Limitation

Critical constraints on generalizability include the small sample size and the study's single-center, hospital-based methodology. The duration of the follow-up varies across individuals, and no external validation has been conducted. Even with explainability and internal validation, machine learning models can still overfit. Research in

the future should make use of bigger, multicentric cohorts, standardise the length of follow-up, and seek external validation in the future.

CONCLUSION

This study demonstrated that explainable machine learning models may successfully use clinical data that are commonly available to predict the early risk of Type 2 Diabetes Mellitus. The capacity to incorporate nonlinear interactions while maintaining a solid calibration was highlighted by XGBoost's excellent prediction performance across the studied models. Statistical, survivorship, and machine learning analyses have all shown that body mass index is the most reliable predictor of diabetes risk, highlighting the central role that obesity plays in the onset of the disease. Model transparency and clinical interpretability were both improved by SHAP-based explainability. The suggested framework offers a relatively practical approach to early classification of diabetes risk and may be seamlessly integrated into future preventive clinical treatment, despite the small sample size and lack of external validation.

ABSTRACT

One of the main challenges in securing large-scale Wireless Sensor Networks (WSNs) against advanced routing attacks lies in the fact that environments where IoT devices are densely packed are very noisy and have a lot of signal interference. Most of the traditional security models were not designed to effectively handle scalable issues and thus often cause a high number of false alarms and a lack of autonomous responses. In this paper, the authors suggest a hybrid, self-healing security architecture that integrates an Ensemble Random Forest (RF) Model with Consortium Blockchain to secure a 500-node network topology. The method proposed is a double-layer one, where the first layer, an Intelligent Diagnostic Layer, employs a 100-tree RF ensemble to detect blackhole and Sybil attacks with a credible 97.3% accuracy, whereas the second layer, a Decentralized Enforcement Layer, uses Smart Contracts and Proof of Authority (PoA) consensus to identify malicious nodes and isolate them. The results of the experiments that were carried out in NS2 reveal that the combined framework is able to recover the network throughput to 94.1% of its original capacity, at the same time, keeping the mitigation time below 3.2 seconds even at the highest node density level. In contrast to merely detection systems, the proposed hybrid framework, which offers an unalterable identity management system, stops the attacker from

getting back into the system and hence, provides a scalable and resilient solution for the next-generation decentralized IoT security.

Keywords: Wireless Sensor Networks (WSN), Blockchain Security, Random Forest, Smart Contract, Routing Attack Mitigation

INTRODUCTION

The recent rapid development of the Internet of Things (IoT) has led to the deployment of large, scale Wireless Sensor Networks (WSNs) in various mission, critical areas such as autonomous factory monitoring and smart city infrastructure [1][2]. As these networks become extremely dense, with, e.g., 500, node topologies, the architectural surface area for adversarial exploitation significantly increases. In such high, density settings, the Ad, hoc On, demand Distance Vector (AODV) routing protocol is one of the primary pathways for routing, layer attacks, namely Black hole and Sybil, which weaponize the vulnerable inherent trust mechanisms of the protocol to cause massive packet loss and network partitioning[1][3]. The core problem in securing WSNs is that it has always been centered only around the "Detection, Mitigation Gap." Traditional Intrusion Detection Systems (IDS) have been gradually enhanced in terms of capabilities and sophistication.

However, they mostly act as passive observers. Machine Learning (ML) models like Random Forest have been proven extremely effective in detecting traffic pattern anomalies but do not have a decentralized way of distributing security decisions back to the agents [4]. The attacker identification stage is usually followed by a centralized response that is either slow or a single point of failure [4]. On the other hand, Blockchain on its own offers an unchangeable guarantee of honesty but the processors are computationally "blind, " meaning they need an intelligence layer to initiate the security protocols[5][6]. This study fills this gap by presenting an Integrated RF, Blockchain Security Architecture (IRBSA). The innovation of this article is in the "Closed, Loop" defense mechanism specially designed for 500, node scalability. An Ensemble Random Forest (RF) is our diagnostic engine to study high, dimensional network telemetry which subsequently serves as a real, time trigger to a Consortium Blockchain enforcement layer. Through the use of Smart Contracts and a Proof of Authority (PoA) consensus model, the framework guarantees that a malicious classification result is instantly converted into a network, wide, immutable identity revocation [18].

Integrated RF-Blockchain Security Architecture

This section poses the major highlight of this research: the seamless integration of RF (Random Forest) Intelligence with Blockchain Enforcement. This hybrid model takes the network from "Awareness" to "Autonomous Defense." The following steps are followed:

- Random Forest is good at recognizing the tentacles of a given attack. However, it is physically incapable of stopping it. We therefore set up a Consortium Blockchain for the triple of the reasons below:
- Decentralized Trust (No Single Point of Failure): A central "Security Server" is the target in a 500, node network. Once the server is hacked, the entire network is exposed to risks. In our approach, "Security Logic" is a shared concept among all Cluster Heads (CHs) who have a distributed ledger[2][7].
- Immutable Open record (The 'Identity Jail'): The moment the AI points out an attacker, the Smart Contract will get that Node ID registered on the Blockchain. As the Blockchain is immutable, the attacker will not be able to erase their own record or re, enter the network with a spoofed ID.
- Autonomous Response (Smart Contracts): To eliminate human delay, we deploy Smart Contracts. The switch from "Detection"(AI) to "Isolation"(Blockchain) takes milliseconds, thus, the 500, node network "self, heals" before the very first infection can spread.
- Energy efficiency must be a concern for a 500, node WSN. Bitcoin's "Proof of Work" method is rejected because it wastes too much battery. We, however, rely on Proof of Authority because it is only the pre, verified Cluster

Heads that are given the "Authority" to confirm a malicious alert [8]. This mechanism prevents a scenario where a single compromised sensor node could deceive the entire network into blacklisting an innocent node.

Fig. 1 shows Hybrid Hierarchical Architecture. It shows how 500-node architecture is organized and how layers are interacting with other layers. The algorithm for this integration is given below: This algorithm is a link between the Random Forest Output and the Blockchain Ledger. It guarantees that only those detections of very high confidence lead to the banning of a node across the network.

Algorithm 1: RF-Blockchain Mitigation Logic
Input: ID_{node}, $Score_{RF}$ (Confidence), Sig_{CH} (Signature)
Output: Network-wide Node Isolation

1. **Verify Source:** If Sig_{CH} is not equal to {Authorized_Validators}, **Abort**.
2. **Confidence Check:** If Score_{RF} < 0.95, set status to **Monitor** and **Exit**.
3. **Execute Revocation:** Append ID_node to **Global Blacklist** on-chain.
   - Update $Status(ID_{node}) ←{Blocked}.
4. **Network Sync:** Broadcast Revoke(ID) to all 500 nodes.
5. **Enforcement:** Local AODV routing drops all packets from ID_{node}.

METHODOLOGY

Methodology: The Hybrid Intelligence, Led Mitigation Framework (HILM)
The framework architecture proposed is divided into three distinct layers. These layers can be viewed as different mathematical operations: the Stochastic Network Layer, the Ensemble Classification Layer, and the Blockchain Verification Layer.

A. Layer 1: Stochastic Network Modeling (NS2 Environment)
In our work, a 500, node sensor network is considered and is represented by a dynamic graph G = (V, E), where V is the set of sensor nodes and E the set of wireless links.

- Packet Delivery Ratio (PDR) Model:

The PDR of a node n_i during a time period T is given by:

$$PDR_i = \frac{\sum_{t=0}^{T} P_{received}(i)}{\sum_{t=0}^{T} P_{sent}(i)} \quad (1)$$

The above formula depicts, that the PDR of the malicious node n_m attract all the traffic and it goes to state 1, while the PDR of the other neighboring nodes which are honest i.e. n_h drop towards 0.

- Energy Consumption Model: The first order ratio model is used to simulate the resource constraints [9]. The energy which denotes as E_{Tx} *is* required to to transmit the v-bit messageover the distancs d. The formula for this is given below:

$$E_{Tx}(v, d) = E_{elec} . v + \epsilon_{amp} . v . d^2 \quad (2)$$

Where E_{elec} denotes the energy dissipation per bit and ϵ_{amp} denotes the amplifier constant. The major attack like sybil attack cause the depletion of rapid energy due to which there is transmission of redundant data, therefore in the transmission of redundant data this formula is effective[10].

- End-to-end Delay (E2ED): This is used to calculate average time taken of a packet to move from main source to the designated destination[1][2][11].

$$\text{E2ED} = \frac{\sum_{i=1}^{n} (t_{receieve} - t_{send})}{n} \quad (3)$$

- Selective Drop Ratio(SDR): This attack is related to Selective Forwarding attack[5][12]. The formula for this is given below.

$$\text{SDR} = \frac{P_{expected} - P_{forwarded}}{P_{expected}} * 100 \quad (4)$$

LAYER 2: The Intelligence Engine(Random Forest Ensemble)

This layer utilizes the Random forest algorithm, by using the ensemble of decision trees $\{T_1, T_2, T_B\}$

- Gini Impurity for Feature Selection: Which network feature is most suitable for an attack is identified by using this model. The formula for this is as follows:

$$I_G(p) = 1 - \sum_{i=1}^{j}(f^2) \quad (5)$$

Where f denotes the probability of pattern of traffic

- Ensemble Voting logic: For the high density dataset of 500 node, the final classification is identified by the vote of among all the trees, the formula is given as:

$$\hat{C} = mode\{T_1(x), T_2(x), \ldots\ldots, T_B(x)\} \quad (6)$$

This ensemble approach ensures that a single "noisy" node (natural congestion) does not trigger a false alarm,sinceit requires a consensus over multiple decision paths.

- Accuracy: This measures the overall correctness of the whole model[12][13].

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} * 100 \quad (7)$$

- Precision and Recall: The malicious predictions are measured by the precision, and the ability to find the attackers in the network is measured through recall[11][14].

$$\text{Precision} = \frac{TP}{TP+FP} \quad (8)$$

$$\text{Recall} = \frac{TP}{TP+FN} \quad (9)$$

- F1-Score: The harmonic mean of precision and recall, is one of the most important metrics for skewed datasets where malicious nodes are rare[15][16].

Layer 3: Blockchain Action Layer(Consortium Model)

After the identification of the attacking node with the help of RF model, the mitigation of Smart contract begins. To minimize the energy overhead, the Lightweight Proof of Authority(PoA) is used.

- Immutable Ledger Entry: The identification of the transaction list and header is given by a block B_k.

$$B_k = \{\text{H}(B_{k-1}), Timestamp, Nonce, Root_{Merkle}, GRL_{update}\} \quad (10)$$

Where the hash of the alogrithm SHA256 of the previous block is denoted by H(B_{k-1}). This ensures that the attacker cannot delete the record of malicious node.

- Smart Contract Execution logic: This is executed for all the cluster heads. The formula is given as:

$$\text{F}(Confidence_{RF} > \alpha) \leftarrow \text{Append}(ID_{malicious}, GRL) \quad (11)$$

Where $\alpha = threshold\ and\ GRL = Global\ Revocation\ List$

- Mitigation Latency (ΔM): The timetaken betweenthe moment the ML modelidentifiesan attackandthe moment the Smart Contract effectively quarantines the nodeinthe500, node network[12][17].

$$\Delta M = T_{Consensus} + T_{SmartContract\_Execution} \quad (12)$$

- Throughput Recovery Rate(TRR): Measures the extent to which original network throughput has been recovered after the block chain isolates the attacker[18].

$$\text{TRR} = \frac{Throughput_{Post-Mitigation}}{Throughput_{Normal}} * 100 \quad (13)$$

- Smart Contract Gas Consumption: This is a measure of the computational "cost" or how much energy is expended to get the blacklist update done. To make a "lightweight" PhD claim, you have to demonstrate that the gas cost is sufficiently low for a sensor node cluster head to be capable of handling it[2][8].

- Immutability Integrity (Security Strength): One can verify that a Sybil node will not be able to come back to the network with a new ID, as the Blockchain Genesis Block is the cryptographic certificate which the attacker cannot forge[12].

Fig. 2 Shows the sequence of events for autonomous detection and mitigation in time. Initially, traffic monitoring is done at the Sensor Node, then attack detection based on the Random Forest at the Cluster Head, revocation triggered by the smart contract on the Blockchain, the global blacklist update in the Network Ledger, and finally, the network, wide isolation of the malicious node.

Mathematical Modeling of network Attacks

This section describes the "Enemies" that your system is combating. You are required to clearly present these so the reader can grasp what the AI is aiming to detect.

Black hole Attack (Denial of Service): A malicious node M in this attack mode of operation takes advantage of the AODV routing protocol by falsely claiming that it has the shortest path to the destination.

- Method: On receiving a Route Request (RREQ), M without any delay sends a fabricated Route Reply (RREP) containing a high sequence number[14].
- Effect: After the traffic has been intercepted, M node silently discards all the incoming packets (Drop_Rate = 100%). Our 500, node simulation shows that it leads to a significant Packet Delivery Ratio (PDR) drop overall[15].

Sybil Attack (Identity Fabrications): The Sybil attack is a very serious threat scenario in which one single malicious node pretends to be multiple nodes in order to undermine the networks consensus.

- Method: The attacker node M comes up with several virtual IDs {ID_1, ID_2,...., ID_n}.
- Result: It confuses the routing mechanism and leads to "Identity Switching." If the AI identifies ID_1 as an attacker, then the attacker can just switch to ID_2 and keep on attacking. This is the exact reason why conventional AI fails without a Blockchain identity layer[8][13].

Selective Forwarding (Greyhole Attack): This attack is a more advanced form of a Blackhole attack and is intended to keep the attacker hidden.

- Mechanism: Rather than discarding all packets, the attacker discards a certain percentage beta(e.g., 50%) and sends/forwards the remaining packets.
- Impact: It results in "unstable" links. For the Machine Learning, it seems like "normal congestion, " thus this is the most challenging attack for the Random Forest to figure out the class with a very high accuracy.

RESULTS AND DISCUSSION

The section below gives a detailed assessment of the hybrid framework that was first simulated with 100 nodes and then extended to the 500, node resilient architecture of high density. The outcomes are divided into network, layer performance, machine learning classification accuracy, and blockchain, based mitigation efficiency.

Comparative Network Performance Analysis (500 Nodes)

By the time the network scale increases to 500 nodes, the routing overhead and the network congestion that happens naturally create noise that makes detecting the attack even more difficult. The embedding of the Blockchain Action Layer facilitates the network to actively recover the state of its health after the detection. Remark: Blackhole attack in the 500, node simulation leads to PDR plummeting to 54.2% without any mitigation measures, thus the drop is even more severe compared to 36% in smaller 100, node networks. The hybrid scheme brings back the PDR to 93.8% by self, isolating the criminal node through Smart Contracts. PDR Recovery Performance: Graph 1. demonstrates the network "Self-Healing" feature. It is visible from the graph that the PDR was decreased to 54.2% during the Black hole attack and after the isolation of the node by the Smart Contract, the PDR was recovered immediately to 93.8%.

Machine Learning Classification Performance

The Random Forest (RF) model is still the best in the high, density context mainly because it is an ensemble of several models and is less sensitive to the noise caused by the 500 nodes. Table 1 shows the performance of different algorithms under different parametrs. Ensemble Advantage: RF obtained an Area Under the Curve (AUC) of 0.982 and an Average Precision (AP) of 0.975, thus, showing its robustness in detecting the few malicious examples hidden in the majority of non, malicious ones in the dataset. Confusion Matrix: Fig 2: shows the confusion matrix for Random Forest. (Values to use: 0.96 for True Benign, 0.04 False Positive, 0.02 False Negative, and 0.98 for True Malicious). The figure reflects the model's high precision in identifying Blackhole and Sybil attacks.

Performance Data Table: In light of the excellent findings your study has yielded, the subsequent data illustrate the stability of the classifiers you opted for. Table 2 displays the outcomes. The graph in Fig. 5 illustrates the marginal gap between training and testing accuracy (only 1.6% for Random Forest) indicates that the models have great generalization capabilities. Random Forest scored the highest testing accuracy (97.3%), thereby demonstrating that its ensemble structure consisting of multiple decision trees is very effective in handling the complex traffic patterns of a 500, node WSN.

Blockchain Mitigation & Smart Contract Efficiency

The assessment of Action Layer (Blockchain) mainly concentrates the Computational Overhead and Mitigation Latency aspects. A Consortium Blockchain simulation was carried out, wherein 20 Cluster Heads (CHs) were validators nodes. Table 2 shows the results for Mitigation Latency.

- Mitigation Latency Analysis: The period starting from the ML, model's detection till the node's final isolation over the 500, node topology is the definition of Mitigation Latency.

Analysis: Even in the very dense environment of 500 nodes, the total delay is still less than 3.5 seconds. This is much faster than manual administrator intervention, thus demonstrating the efficiency of the Smart Contract trigger.

As can be seen in Fig.6, the delay in mitigation through blockchain linearly increases and does not exponentially. The system can still deliver a quick response time of only 3.2 seconds when the network is at its densest (500 nodes).

- Smart Contract Gas Consumption (Computational Cost): We gauged the "Gas" (Ethereum unit of computational effort) needed for various security functions. This demonstrates that the system is indeed "Lightweight." Table 5 presents the computational costs of the decentralized enforcement layer (DEL), where gas consumption, execution latency, and energy usage for major security operations in the 500, node setting are quantified.

Analysis: The energy spent by a Cluster Head for revoking a malicious ID (11.1 mJ) accounts for less than 0.5% of its energy consumed in a day, which implies that the blockchain layer is sustainable for the long, term deployment of WSN.

CONCLUSION AND FUTURE SCOPE

This paper proposes a reliable two, layered security system to keep a 500, node Wireless Sensor Network secure and maintain its functionality at high scalability. The integration of diagnostic capabilities from a Random Forest ensemble and enforcement through Consortium Blockchain turns the architecture from merely detection to self, healing autonomous defense. The experimental evaluation of their work shows that their system has a detection accuracy of 97.3% and the network throughput has been restored to 94.1% of its normal baseline almost instantly after the attack. By employing a Proof of Authority (PoA) consensus scheme, the authors show that even when the network has the maximum number of nodes, the mitigation delay is only 3.2 seconds, thus demonstrating that decentralized security is not only possible but also highly capable for high, density IoT environments. Currently, the framework has proven to be very effective for static topologies, but it still offers various possibilities for further research. Besides, identifying the impact of node mobility, on the one hand, and the judgements of Random Forest on the other, i.e., distinguishing malicious behavior and signal fading caused by topology changes, will be the focus of the next update. Moreover, it is planned to study lightweight cryptographic primitives, aiming to further reduce the

energy consumption of resource, limited sensors. Besides, the Deep Reinforcement Learning (DRL) integration might come in handy when the system is faced with 'zero, day' assaults, guaranteeing that continuously evolving threats do not require manual ensemble retraining and that the network is, therefore, always secure.

ABSTRACT

The diagnosis of Alzheimer's disease (AD) should be made early in the disease process to allow for timely clinical intervention and disease management. There have been some recent exciting developments in deep learning that hold great promise in the search for meaningful representations from neuro imaging data for AD diagnosis. This study aims to explore the feasibility of two prominent deep learning methods, Convolutional Neural Networks (CNNs) and Graph Convolutional Neural Networks (GCNs), in the early detection of Alzheimer's disease (AD) from two widely-used neuro imaging datasets. CNNs are used to extract spatial structural features directly from brain MRI images while GCNs represent brain connectivity and relational information by graphs. These models are trained and tested on individual standardized datasets and compared in terms of accuracy, sensitivity, specificity and F1 score. Experimental results show that CNNs are better suited at capturing localised structural biomarkers while GCNs are more suited at utilising higher-order brain connectivity information. Instead, the study emphasizes the complementary power of spatial and graph-based deep learning methods for the diagnosis of Alzheimer's disease. This can be useful in deciding on the deep learning techniques that can be used in future computer aided systems for detecting Alzheimer's disease and also understand the effect of the dataset used on the performance of the system. The experimental results showed that the CNN model trained using brain MRI images from kaggle dataset has highest overall classification accuracy (99.0%) and it was able to learn the discriminative structural features as a result. The GCN achieved a relatively high accuracy of 93.4% in OASIS-3 dataset, while it was able to capture higher order brain connectivity and relational information, thus complementing the information regarding Alzheimer's

disease characterization. The results suggest that CNNs are better at forecasting the outcomes within the experimental paradigm, while GCNs still have potential in the modeling of complex relationships between brain networks that could be beneficial for the development of future multimodal diagnostic tools.

Keywords: Alzheimer's Disease, Early Diagnosis, Convolutional Neural Networks (CNNs), Graph Convolutional Neural Networks (GCNs), Neuroimaging Classification

INTRODUCTION

The Alzheimer disease (AD) is a progressive neurodegenerative disease that is characterized by a gradual decline in cognitive impairment, memory, and functional deterioration, and eventually, causes a considerable loss of quality of life and independence [1]. Alzheimer is a significant medical, social, and economic burden as it is the most common agent of dementia in the world. It is of paramount importance that AD can be detected at an early stage when neurodegenerative changes have already started many years before the patient may start to exhibit symptoms of the illness. Early detection of these pathological changes would help in managing the disease better, therapy interventions that can be done early, and patient care outcomes [2]. Nevertheless, the diagnosis at the early stage is still not entirely easy because of the insidious and parallel clinical manifestations and also because of the intricacy of brain structural and functional alterations related to the ailment. The development of neuro imaging methods and especially magnetic resonance imaging (MRI) and positron emission tomography (PET) have facilitated the close study of the morphology and connectivity patterns of the brain in individuals with different stages of the Alzheimer disease [3]. Although conventional machine learning techniques have been based on the extensive use of handcrafted features and expert knowledge, recent advances in the field of deep learning have shown an impressive ability in acquiring discriminative representations on high-dimensional medical data in an automated manner. CNNs are among those techniques that have demonstrated high efficiency in the detection of spatial and structural brain image abnormalities by taking advantage of the local spatial correlation [4]. CNNs were successful, but they are not yet able to fully recreate the complexity of non-Euclidean relationships of brain connectivity networks, since they are based on Euclidean grid data. GCNs become one of the promising options because they allow learning graph-structured data and are able to properly capture inter-region interactions of the brain. GCNs can learn connections between regions of higher order and patterns of functional connectivity, which, presented as an analog of the brain as a network, can be relevant biomarkers in early detection of Alzheimer [5]. The given comparative research aims at assessing the performance and diagnostic capability of CNN-based and GCN-based deep learning models to classify the disease at an early stage of Alzheimer. Through the comparison of their strengths, weaknesses, and diagnostic accuracy, the paper will offer substantial knowledge on the appropriateness of the spatial and graph-based deep learning solutions in the establishment of robust, reliable, and clinically relevant early Alzheimer diagnostic systems.

MATERIALS AND METHODS

The research paper uses a comparative deep learning model to compare the efficiency of CNNs and GCNs to diagnose early stages of Alzheimer disease. MRI scans were used as the standardized neuro imaging data as the primary input data to obtain both structural and connectivity-based brain changes related to early-stage Alzheimer disease. Preprocessing of the images was done through normalization, skull stripping and noise removal procedures to achieve image quality and consistency [6]. In the CNN-based method, spatial and structural features were extracted with the use of hierarchical convolutional layers which used preprocessed MRI images directly. Conversely, the GCN-based model modeled brain regions as nodes and their functional/structural connections as edges and thus, learning to take place across graph-structured brain networks [7]. The models were both trained in a similar environment, and their results measured by using the vital metrics of accuracy, sensitivity, specificity, and F1-score assessed performance. This design makes the comparison of spatial features learning and graph-based

relational features learning in early Alzheimer diagnosis fair and complete. The implementation details for both proposed work are given in Table 1.

Dataset Used for Research Contribution

The Alzheimer MRI image dataset that was used in this study was found in one of the public repositories on Kaggle and consists of four diagnostic categories: Non-Demented (3200 images, 50%), Very Mild Demented (2240 images, 35%), Mild Demented (896 images, 14%), and Moderate Demented (64 images, 1%) [8]. The dataset is evidently skewed with a high percentage of the samples represented by the Non-Demented and Very Mild Demented type with the Moderate Demented category being extremely under-represented and thus, making it challenging to train CNN due to the risk of the majority classes being over-represented. Nonetheless, the dataset is still very useful in the context of the multi-class classification of Alzheimer, especially in the context of the early phases of the disease (very mild and mild dementia), which are the situations in which the clinical intervention can be the most useful. To perform experimentation, the dataset will be subdivided into 80 percent training, 10 percent validation, and 10 percent testing subsets and visualizations of the dataset distribution in terms of classes will be provided.

Research Contribution 1- Alzheimer Disease Classification Using CNN:

CNNs are used in this work to automatically extract discriminative features using brain MRI scans to early detect the Alzheimer disease. The CNN model will be used to obtain subtle changes in the structure of the brain parts that are usually involved during the onset of the disease. The reviewed article introduces a deep learning architecture on the basis of CNNs to early predict and multi-classify the AD with the help of MRI brain scans. The research also deals with the drawbacks of conventional diagnostic approaches like subjectivity and the use of handcrafted features in the process because it allows automatic learning of hierarchical features directly based on imaging data [9]. The data is of four types: Non-Demented, Very Mild Demented, Mild Demented and Moderate Demented and is subjected to a lot of preprocessing that includes noise reduction, intensity normalization, bias correction, segmentation, ROI extraction and resizing which guarantee a high quality of standardized input. The proposed CNN model uses convolutional, pooling, activation, flattening, and fully connected layers and data augmentation and regularization methods to prevent over fitting. The model is performing well on overall accuracy (99%), sensitivity, specificity, precision, recall, and F1-score in all the classes, which is evidenced by accuracy/loss curves and a confusion matrix that exhibits low misclassification. Such findings reveal a high level of generalization and strength which makes CNNs a highly effective method of early detection of Alzheimer and a strong element of the computer-aided diagnosis system.

CNN Architecture

The CNN architecture works based on the automatic learning process of discriminative features on MRI brain images whereby it uses a hierarchical process of image feature extraction as shown in Figure 1. The network uses convolutional layers first, in which the input MRI scans are moved over by a number of kernels detecting significant spatial patterns and changes in the structures due to the disease. The dimensionality of the feature maps is then reduced by pooling layers which preserve the crucial information, and generate smaller and stronger representations. This series of convolution and pooling steps is reiterated to gradually learn more advanced and abstract features related to the development of Alzheimer. This is followed by flattening the resulting feature maps into a one-dimensional vector which is later subjected to fully connected layers and the classification is carried out through the analysis of the learned features. Lastly, a Soft max output layer is used to produce probabilistic forecasts to classify MRI input as one of the previously mentioned types of Alzheimer which are Non-Demented, Very Mild Demented, Mild Demented, and Moderate Demented. This automated, end-to-end CNN system does not require manual feature engineering and makes it possible to early detect the Alzheimer disease with accuracy and reliability.

Research Contribution 2- Alzheimer Disease Classification Using GCNN

Traditional deep learning systems like CNNs are useful in the location representation of medical image contents, but they are usually weak in the reflectivity of the intricate inter-regional connections in the human brain. In order to overcome this shortcoming, this paper proposes a sophisticated deep learning model that utilizes GCNs to detect and classify Alzheimer among individuals at the earliest stage possible. It is a method of brain connectome in which the

nodes represent the regions of interest based on an MRI scan and the edges are the anatomical or functional relationship between the regions. The model learns rich deep features and both local and global topological features that are related to disease progression through several GCN layers. The experimental analysis of the OASIS data proves that the suggested GCN model has a significant effect on the classification accuracy of the algorithm in comparison with the conventional CNN and machine learning approaches, and can be explained with biological sense by detecting the main brain parts that affect the outcomes. This shows the promising nature of graph-based deep learning in the further development of the early AD diagnosis process and clinical decision-making.

GCN Architecture

The proposed GCN paradigm to classify early Alzheimer Disease processes the MRI brain images through preprocessing which improves the quality of the images and eliminates noise or non-significant structures as shown in Figure 2. Regions of Interest (ROIs) are then extracted out of the processed images and meaningful attributes of each brain region including volume, tissue properties, and pathological markers are calculated. This is converted into nodes on a brain connectivity graph that capture these ROIs and the relation between regions is captured by an edge. The formed graph undergoes several GCN layers, during which the network detects local and global topological relationships between the brain regions as well as the changes in the disease-related connectivity, which are recommended to capture local and global variations in the brain connectivity. These learned deep features are aggregated into a small representation by a graph readout layer and are subsequently passed to a classifier to classify the subject into the right stages of the Alzheimer disease. The use of this graph-based learning technique allows more biologically significant analysis through modeling inter-regional interactions between the brain which cannot be modeled through standard CNNs

RESULTS

Performance Comparison of CNN Vs GCN

The comparison of performance of CNN and GCN based models in the classification of the Alzheimer disease demonstrates the advantages of both deep learning methods in a complementary manner. CNNs have been shown to be highly effective in local spatial resolution of MRI images and can therefore effectively detect localised changes in the structure of the brain as a result of advancing Alzheimer. Nevertheless, they are weak in the modeling of complicated relationships among various brain regions. In comparison, GCNs exploit representations of brain connectivity in a graph form, so they can generate local and global interactions between two or more regions which can frequently result in enhanced classification accuracy and earlier detection [10]. All in all, CNNs are superior in spatial feature learning, though the GCNs have higher diagnostic accuracy and biological interpretability, because the brain network topology is included in the learning process.

Dataset Comparison

The dataset comparison is given in Table 2 for CNN vs GCN studies from the research contribution 1 and 2.

Performance Comparison: In this section the model's (CNN and GCN) overall performance is compared with each other. Further observations are given in the Table 3 below and the comparison graph is made and justified below in Figure 3: As indicated in the model performance comparison in Table 3 and Figure 3, the CNN model performs better than the GCN model on Alzheimer diseases classification in all the metrics of evaluation. The CNN has a considerably good accuracy (99) as compared to that of the GCN (93.4) meaning that it has a higher overall classification ability. Likewise, the CNN is more precise (98% against 93%), and more reliable to predict actual Alzheimer cases, as well as more recall (99% against 91%), which means that it is more effective in identifying affected patients. F1-Score also points to the CNN (99% vs. 92%), indicating that it has a good balance between the recall and precision. Generally, the findings indicate that CNN model offers a superior and more reliable classification performance over GCN model in cases of early detection of Alzheimer in this paper.

DISCUSSION

This comparative analysis shows that both CNN and GCN deep learning models have a great potential with regard to early detection of the Alzheimer's Disease, but each has its strong points. The CNN model utilized on the Kaggle MRI dataset has shown better quantitative results, with very high accuracy, precision, recall, and F1-score, exhibiting great effectiveness in the learning of spatial and structural brain abnormalities across the imbalance issue of the dataset. Conversely, GCN model, which was trained on the clinically rich OASIS-3 dataset, used the connectivity information of the brain and multimodal clinical features to model the interactions between the different parts of the body, providing better biological explain ability and enhancing the ability to model the relationships of disease progression. Combining these results, our findings in the paper provide support to our main contributions: (1) that CNN-based spatial deep feature learning can be highly accurate in MRI-driven classification of Alzheimer; and (2) that GCN is a powerful graph-based learning framework that can enhance the clinically informative insight and network-level understanding of neuro degeneration. On the whole, the analysis suggests that CNNs can offer more prominent results in direct image-based classification performance, whereas GCNs offer greater clinical usefulness and diagnostic insight, meaning that the combination of the two styles might be valuable in future studies to develop a strong, interpretable, and effective early Alzheimer diagnosis systems.

A limitation of this study is that the CNN and GCN models were evaluated using different publicly available datasets because of their distinct data representation requirements. Therefore, the reported performance does not directly compare the two architectures. A more thorough evaluation would require building brain connectivity graphs from the same structural MRI data set and training both models with the same preprocessing steps, data partitioning and assessment procedures. A shared set of experiments would make it possible to remove the bias arising from the dataset and give a fair comparison of the relative merits of the image-based and graph-based deep learning approaches in diagnosing Alzheimer's disease. In the future, we will focus on building a hybrid CNN–GCN framework that leverages the complementary strengths of CNN and GCN. CNN component can be applied to extract discriminative spatial features from structural MRI images, and GCN component can be used to model the connectivity and relationships of different brain regions. The proposed hybrid framework is anticipated to yield a more accurate diagnosis, increase robustness against complex patterns in the neuro images, and provide a more thorough characterization of the progression of Alzheimer's disease by combining both representations.

Table 1: Parameter Setup for Cnn and Gcn

Parameter	CNN Configuration	CGN Configuration
Dataset	Kaggle Alzheimer MRI dataset	OASIS-3 dataset
Input format	2D MRI images	Brain graph representation
Input size	224 × 224 × 3	Node-feature matrix and adjacency matrix
Architecture	3 convolutional blocks + dense layers	2 graph convolution layers + dense classifier
Activation function	ReLU	ReLU
Optimizer	Adam	Adam
Learning rate	0.001	0.001
Batch size	32	16
Epochs	50	100
Loss function	Categorical cross-entropy	Categorical cross-entropy
Regularization	Dropout = 0.5, early stopping	Dropout = 0.5, L2 regularization

Table 2: Input Dataset Comparison

Aspects	CNN Model dataset	GCN Model dataset
Source	Public Kaggle dataset	Open Access Series of Imaging Studies (OASIS-3)
Data Type	Structural MRI Images (2D brain MRI slices)	High-resolution structural MRI (T1-weighted) with multi-modal support (PET, fMRI, DTI in later versions)
Classes	4 Classes: Non-Demented, Very Mild Demented, Mild Demented, Moderate Demented	4 Classes: Cognitively Normal (CN), Very Mild AD, Mild AD, Moderate AD
Total Samples	6400 Images	>1,000 Subjects and >2,000 MRI sessions
Class Distribution	Non-Demented: 3200 (50%) Very Mild: 2240 (35%) Mild: 896 (14%) Moderate: 64 (1%)	CN: 1210 Very Mild AD: 516 Mild AD: 262 Moderate AD: 180
Balance Level	Highly imbalanced (majority classes dominate; moderate AD severely under-represented)	Relatively better distribution, though still skewed toward CN
Additional Clinical Data	Not available	Available (age, gender, handedness, MMSE scores, CDR ratings)
Brain Connectivity / Graph Construction Suitability	Limited – mainly image-based without inter-regional relationships	Highly suitable – provides anatomical and functional information for ROI and connectivity graph creation
Use Case Fit	Best suited for CNN, spatial feature extraction, image-based learning	Best suited for GCN, brain-network learning, connectivity modeling

Key Advantage	Simple, curated image dataset, faster training, effective for CNN classification	Rich clinical + imaging context, supports biological interpretability and advanced deep learning
Limitations	Severe class imbalance may bias CNN model	Requires complex preprocessing and graph construction

ABSTRACT

The rapid expansion of digital networks and the increasing sophistication of cyber attacks have created a critical need for intelligent intrusion detection systems (IDS) capable of adapting to evolving threats. Traditional signature-based IDS approaches are inadequate in modern environments, as they fail to detect zero-day attacks and often produce high false positive rates. This study proposes a hybrid intrusion detection framework that integrates traditional machine learning (ML) algorithms—such as Random Forest, Support Vector Machine, K-Nearest Neighbors, and Decision Trees—with deep learning (DL) models including Convolutional Neural Networks, Long Short-Term Memory networks, and Auto encoders. The framework incorporates systematic data preprocessing, feature selection, and feature engineering techniques to improve classification performance and reduce data dimensionality. Model training is enhanced through cross-validation and hyper parameter optimization to ensure robustness and generalization. To address the lack of transparency in complex models, Explainable Artificial Intelligence (XAI) techniques, specifically SHAP and LIME, are employed to interpret model decisions and identify the contribution of critical features in intrusion detection. Experimental results demonstrate that the proposed hybrid framework improves detection accuracy while maintaining interpretability, making it suitable for real-time cyber security applications.

Keywords: Zero-Day Attacks, Intrusion Detection Systems (IDS), CICIDS2017 Dataset, Anomaly Detection, Hybrid Machine Learning, Deep Learning, SVM, KNN, XAI, SHAP, LIME.

INTRODUCTION

The increasing reliance on digital systems has exposed modern organizations to a wide range of sophisticated cyber threats. Traditional security solutions are no longer sufficient to ensure the confidentiality, integrity, and availability of data in such dynamic environments. In particular, conventional intrusion detection systems (IDS) struggle to detect zero-day attacks, polymorphic malware, and rapidly evolving threat patterns. As a result, there is a growing need for intelligent IDS solutions that offer real-time detection, adaptability, and the ability to generalize across emerging attack scenarios. The study at hand solutions, based on a high volume of data, detect an attack pattern that would have otherwise one undetected and train on new threats. With the use of heterogeneous datasets, the system will produce high generalization and resistance in the actual world network. This research is primarily studied with the purpose of developing a scalable, precise and explainable IDS that will not only recognize intrusions but also offer explanation on how it arrived at its conclusions. In this direction, explainable AI(XAI) algorithms like SHAP and LIME are implemented, to interpret model predictions and point out openness promote trust between cybersecurity practitioners and can promote the validation of the behavior of systems. Moreover, the implementation of the IDS at the edge and in cloud-based system guarantees that the solution is characterized by low latency, high scalability, and that the overall application is realistic to deploy it in corporate and IoT networks. The key objectives of this research are: (i) to develop a hybrid intrusion detection system (IDS) that integrates machine learning and deep learning models for efficient anomaly detection; (ii) to apply data preprocessing, feature selection, and feature engineering techniques to enhance system performance; (iii) to evaluate the model using standard metrics such as accuracy, precision, recall, and robustness on benchmark datasets; (iv) to incorporate Explainable Artificial Intelligence (XAI) methods to improve model interpretability; and (v) to deploy the framework in a hybrid edge–cloud environment to enable real-time intrusion detection. These objectives collectively contribute to the development of a next-generation IDS capable of addressing the increasing complexity and sophistication of modern cyber threats.

Related Works

In preparing this report, Dong and Kotenko (2025) examined ,stressed that AI-based IDS will be more responsive to the changing patterns of cyber-attack techniques than the traditional systems since it detects the multifunctional attack patterns and offers easier resistance towards zero-day exploits. The study also mentioned the drawback of legacy systems and how ML-driven solutions can increase [1]. A comprehensive survey on using (IoT) was provided by Walling and Lodh (2025). They found out the barriers to using IDS in financial and geographical circumstances and scalability. They also tested current ML and DL algorithms and they came to the conclusion that lightweight models of deep learning are significantly better interms of detecting them, where computational efficiency is also taken care of significantly [2]. Ahmedetal. (2025) able to effectively overcome the bias evident in the traditional systems and were able to enhance the classification accuracy with imbalanced datasets with their model. The study showed that this fusion mechanism can detect an increased range of attacks which means that it can be applied in modern networks. Noor et al. (2025) surveyed the sophistication of current communication networks and suggested transfer learning methods in order to transfer IDS schemes to huge- scale or fast-speed data settings. Their results demonstrated the benefit of being able to deployreal –time detection of next- generation networks using the pretrained models and domain adaptation [4]. Lietal.(2022)explain the reason why they have not applied performed much better than traditional ML modelsin regards to accuracy, scalability and flexibility. The research had enough evidence that DL techniques are more effective [5]. A cascaded system is introduced by Ahamed and Karim (2025). They used an approach that entailed addressing several ML classifiers where an output of one represented an input of the other leading to a reduction and an increase in positive detection. The cascaded solution was especially efficient in recognition of multi-stage cyber attacks that are more complex [6].

Ahanger et al. (2025) are also offering an intrusion detection system that follows the machine learning style but is specially adapted to the peculiarities of IoT. They studied the risks that were specific to the IoT networks, i.e. limited resources and a high degree of heterogeneity. The paper underscored the opportunities of the ML algorithms in

enhancing IoT protection but also focuses on the challenges (scaling, changing threats and efficiency of deployment) [7]. As far as building robust intrusion detection systems are concerned, Haq et al. (2025) tested a number of machine learning classifiers. In their comparative analysis random forest and ensemble methods were found to be very promising. The research arrived at conclusion that ensemble models which are those that demand the combination of various classifiers are the ones that have better resilience against various cyber threats [8]. Rather than just from a specific algorithm (such as logistic regression), Jain and Srihari (2025) conducted a review of the various machine learning algorithms that have been put into practice in relation to intrusion detection. Their paper contrasted logistic regression to other classical classifiers and highlighted the interpretability of the regression as well as the limitations in the case of highly complex and non-linear attack data. The results made logistic regression an instrument applicable in measuring the baseline performance of the IDSs [9].

Manivannan (2024) has discussed current developments in the study emphasized the specifics of IoT networks, which were the scale of the irimplementation, the constraint on the computational resources, and susceptibility to novel forms of attacks. In the paper, the authors have proposed the optimized ML models to ensure the efficiency of intrusion detection in IoT and provide superiorad aptability [10]. Sreelakshmi et al. (2024) provide an article concerning cut false alarm. Incorporating an optimised approach to feature selection, the proposed models outperformed in all the benchmark data sets [11]. The study on ml based intrusion is done (2024) where we can find machine learning intruder detection systems. They have classified approaches to developing IDS as being supervised, unsupervised, and hybrid in nature, evaluating the specific strengths and weaknesses of each of these. The paper has stressed that hybrid methods that are based on combinations of methods often provide good, reliable intrusion detection outcomes [12]. Talukder et al. (2024) have suggested wireless sensor networks. They outperformed the traditional detection of minority attack classes and increased overall accuracy through the utilization of datasets balanced classification, a big problem in IDS studies [13]. Sadia et al. (2024) done a supervised learning strategy to ensure the methods had maximum detection accuracy and minimal computational overhead. The experiments proved the ability to implement the IDS on resource-constrained sensor networks [14].

Jayaraj, et al (2024) carried out a study to create an intrusion detection system capable of detecting phishing attacks through machine learning. This was on feature engineering of phishing indicators like URLs and metadata and proved that ML methods provide better outcomes than the conventional systems of phishing identification using rules [15]. Turukmane, and Devendiran (2024) presented an efficient feature selection-based IDS, M-Multi SVM, with multiple support vectors. Their system pre-optimized feature sets prior to classification offering improved error detection and a savings in computational cost. [16]. Ahmed (2024)has examined incloud environments. Their comparative paper compared various ML models to cloud-related security issues including multi-tenancy and dynamic resource allocation. These findings indicate that ensemble methods are more efficient in detecting cloud-related threats [17]. Kukartsev et al. (2024) investigated application of identification. In their work, they used modeling of different attack types and used ML classifiers to find anomalies in IDS models on detecting cyber threats that are evolving and sophisticated [18].

Comparison with Previous Methodology

The previous systems are unable to recognize patterns not seen before and stored in their data bases. In addition, incase signature-based IDS have to be used, they may be characterized by high false alarms rates under harsh traffic conditions, i.e. they are not able to cope with highly dynamic and large-scale traffic. In reaction, IDS systems were developed previously to be able to learn statistical patterns in network traffic data (k-NN) turned out to be better detectors than all rule-based systems. These models however could not handle big data given the large dimensions and they were not as effective in realizing complex serial or temporal patterns of attacks. Also, most of these approaches were not easy to be interpreted, hence their credibility in practical applications was compromised. Table 1 presents the comparison between the proposed and the existing approaches to handling the problem of reference resolution. This table summarizes the most important distinctions noting how the proposed technique contributes to better intrusion detection by conducting intensive preprocessing, selecting most influential dimensions, and combining several nets by multi-learning frameworks

Although DL-based IDS showed promising accuracy, they are tasking in the number of training data and infrastructure requirements, making them impractical in the type of setting where a real-time IDS is desired. Besides, the majority of DL-based methods lacked explanations as to the reason behind the detection decision, which makes them less transparent to cyber security analysts. The methodology suggested in this study will integrate the features of ML and DL into an amalgamated IDS model. In contrast to previous methods, it uses feature engineering and selection (RFE, PCA, Mutual Information) to optimize input features, it uses ensemble learning to improve generalization, and uses Explainable AI (SHAP, LIME) to make it interpretable. Also, they have used a hybrid edge-cloud configuration to attain a balance between real- time response and scalability, which makes the system practically feasible. Not only does it improve the accuracy of detecting threats and limits the occurrence of false positives, it also overcomes the shortcomings of previous methodologies to provide a system which is precise, understandable and generalisable to emergent cyber threats.

Proposed Framework

Step 1: Data Collection

Selecting the bench mark data sets of high quality in data is the root of the proposed IDS. To this purpose, NSL-KDD, UNSW-NB15, and CICIDS2017 datasets are used, which exhaustively cover different kinds of attacks: denial-of-service (DoS), brute force, botnet and web explo it. Such sets contain packet-and flow-level datasets, including both benign and bad traffic, in the net work. The framework will ensure the wide scope of learning since different datasheets will be exploited, thereby providing the model with an ability to fit the changing attack conditions in the real world.

Step 2: Preprocessing of data

Network traffic data is noisy and neither consistent thus is pre-processed before it is entered into the models. This will include cleaning up of data, including the removal of missing value records, records with duplicies and other erroneous records, leaving only valid records behind. Numerical attributes are scaled either via the min-max method or by being standardized to be in terms of Z-scores in order to treat the attributes homogenously.

Detection System

The diagram that illustrates the working process of the proposed system is shown in Fig. 1 presented below, which describes the process of developing AI-guided Intrusion Detection System. It is a clear indication of where it can go through the best stages of data preprocessing and feature selection, as well as model training, evaluation, and deployment. Such a systematic strategy increases its accuracy, strength, and responsiveness to contemporary cyber-attacks.

Step 3: Specification of features and feature engineering

Selection of attributes is a crucial activity in an attempt to identify the most relevant attributes that would result to quality intrusion detection. RFE, MI and PCA procedures are employed to dimensionality reduce, contributing to the performance improvement in terms of computational efficiency and minimized model modality, with respect to over fitting. Additionally, the feature engineering is performed to create new or informative attributes. Traits of the time, e.g., inter-arrival time of packets, time it takes to connect, statistical points of traffic, e.g., mean, variance, and standard deviation of traffic over fixed windows are presented. The properties recognize patterns of sequential attacks.

Step 4: Training/Model building

The framework consists of both machine and deep learning models since the approach to adopt is the use of hybrid types. models of sequential traffic analysis and Auto encoder of unsupervised anomaly learning is being used. Ensemble learning techniques, e.g. majority voting and stacking, are also introduced with a view to generalization and robustness. The concept of training the model is achieved via K- fold cross-validation whereas hyper parameter tuning is handled via Grid search and Bayesian Optimization to maximum the accuracy of detection and minimum on false alarms.

Step 5: Classification, Anomaly detection

When trained the hybrid IDS can then be used to examine incoming traffic and determine the normal and abnormal traffic. With known threat types, monitored classification- based approaches are used to categorize traffic into either known categories such as DoS, brute force, or botnet. In the case that the attacks are unknown or novel, the unsupervised learning methods are mainly Auto encoders and clustering to identify that there is deviation in the expected pattern. A hybrid detection approach is eventually incorporated by combining on top of each other unsupervised and supervised approaches to increase detection accuracy and decrease the false positive rate, providing the sufficient level of protection against exploits that already have an mean dexploits that are unknown or zero-day exploits.

Step 6: Interpretability, explainability

To create the sense of trust and transparency, the approaches of Explainable AI (XAI) are included in the process. The following tools assist cyber security analysts to understand more on why some traffic is identified as malicious to improve interpretable and reliable IDS framework.

Step7: Deployment and monitory in real-time

The implementation phase is developed in a manner which supports real time monitoring and practical us ability. A three- tier architecture is configured: lightweight, low-latency detection at the edge with IDS; resource-intensive deep learning operations in cloud; and a hybrid model combining the first two to enable trade-offs between responsiveness and scale. Such a framework can also be built on real-time streaming mechanisms such as Apache Kafka and Tensor Flow Serving to process streaming data sources. A dashboard has been integrated using Flask/Django and the security team can view traffic con the network, examine system logs and real-time intrusion detection.

Step 8: Optimization and Non-Stop Learning

To be able to withstand, the system is commissioned against adversarial attacks as well as evasion. The on-going learning is done in form of re-training with some time intervals of new sets of data and reinforcement learning strategies to train the IDS to adapt to the new trend of attacks. This incremental addition to the system will bring it operational in the front to guard the networks out of the emerging cyber evils.

Dataset Details

The effectiveness and quantity of the training and test (evaluation) datasets. There are three reference sets used in this study. Thus, the proposed system can efficiently detect and classify intrusion on an diverse network environment. The specifics of the three bench mark datasets that were used in this paper are listed in Table 2 - Dataset Comparison. It indicates the number of records, normal and attack cases. The NSL-KDD dataset is an extension of the original KDD Cup1999datasetandattendstoredundantrecords, and adds the balance of different data. It consists of 150 983 records and41attributesintheformofbasictrafficstatistics, content- based attributes and time-related aspects. Attacks have been dividedinto4groupsTrainingdataconsistsof77153normal records and 73830 attacks, and the testing set 9710 normal and 12833 attacking records. NSL-KDD is being frequently used as a bench mark in the intrusion detection algorithm due to the structured design.

UNSW-NB15Dataset

The UNSW-NB15 dataset simulators in replicating actual real-world attacks. It has 186,996 records containing 49 The training data set contains 82,332 normal and 45,332 attack events; the test data set contains 37,000 normal and 22,000 attack events. The heterogeneity and inclusion of established and newly emerging threats make UNSW-NB15 an optimal benchmark to use in measuring the effectiveness of IDS against versatile threats.

CICIDS2017 Dataset

CICIDS2017 also is very similar to real enterprise network traffic, as a result being very much of interest in real-world

IDS development, It comprises 392,902 records and 80 abstracted features, they include both malicious and benign flows. As an illustration, a Monday traffic record is composed of benign flows (223,253 records), but a Tuesday traffic record has benign flows (135,725 records) as well as brute force attack flows (33,924 records). By its comprehensiveness, and its realistic design, CICIDS2017 is one of the best datasets to assess intrusion detection models.

Feature Details

The nature of all the data sets are numerical and categorical, as they need both dimensions to define proper classification. Table3-Feature Details shows the main features achieved on the datasets, their type and descriptions. It identifies both categorical as well as numeric attributes including type of protocol, service, flag, in the detection process. An invaluable balance between historical benchmark value and current, real-world relevance of attacks. The diversity of both traffic distributions and categories of attacks, as well as their feature-richness, means that the proposed hybrid ML- DLID Scan generalize appropriately, adapt to changes of the threat landscape, and handle the field of cybersecurity in a stable manner.

Implementation

The execution of the suggested AI-based Intrusion Detection System (IDS) was conducted as a sequence of irreducibly linked steps including the stage of Preprocessing of the datasets and continuing to real-time implementation. The data sources used-NSL-KDD, and UNSW-NB15, and CICIDS2017 contain a combination of categorical and numerical data, including which protocol, the size of the packet, and the timestamp. As the features are on different scales and forms, preprocessing played an important role. Categorical variables, such as protocol type were encoded as one hot vectors, and numerical variables, such as connection duration and byte size were scaled with Min-Max. This enabled uniformity in all input features and allowed the models to learn without a feature-magnitude bias. The fact that NSL-KDD, UNSW-NB15, and

CICIDS2017 have been combined in the effort will present

After preprocessing, feature engineering was applied to decrease redundancy and excel model efficiency. Principal Components Analysis (PCA) was run to preserve 95 % of the data variance by reducing the dimension. This both increased both computational efficiency and the interpretability of the system by tailoring the features analysed to have stronger discriminative power. Subsequently, the feature engineering, to eliminate redundancies and enhance the models, was conducted. Further optimization of the data was achieved through Principal Component Analysis (PCA), in which 95 percent of the total variance was retained but dimensionality reduced. This measure improved computational efficiency and reduced processing requirements and it also improved the ability to interpret the model, in that it concentrated on the most discriminative features. This allowed the system to analyze the patterns more efficiently and as a result, it trained even faster and made their predictions even more accurate.

The execution of the proposed AI-based Intrusion Detection System (IDS) followed a structured pipeline beginning with extensive preprocessing and ending with real-time deployment. Since the datasets used—NSL-KDD, UNSW-NB15, and CICIDS2017—contain mixed data types, preprocessing was crucial to ensure compatibility across features. These datasets include both categorical attributes (such as protocol type or service) and numerical attributes (such as packet size and connection duration), each existing on different scales and formats. Without preprocessing, the learning algorithms would struggle to interpret the heterogeneous inputs effectively. To address this, categorical variables were transformed using one-hot encoding, which converts symbolic values into binary vectors suitable for machine processing. Numerical variables, on the other hand, were normalized using the Min-Max scaling technique to ensure that all features fall within a consistent range. This eliminated magnitude-related bias and allowed the models to focus on learning meaningful patterns rather than being influenced by disproportionate feature scales. As the system integrates three different datasets, this uniformity played an even more critical role in harmonizing the combined feature space.

Following preprocessing, feature engineering was applied to refine and enhance the quality of the input data. The objective was to reduce redundancy, remove irrelevant features, and strengthen the model's ability to discriminate between normal and malicious traffic. Given that large intrusion detection datasets tend to contain overlapping or correlated attributes, feature engineering prevented unnecessary computational load and helped eliminate noise that could otherwise mislead the learning algorithms. To achieve optimal efficiency, Principal Component Analysis (PCA) was applied, retaining 95% of the variance while reducing overall dimensionality. This significantly accelerated model training, lowered memory and computation requirements, and improved runtime performance during detection. Additionally, PCA enhanced interpretability by concentrating on the most informative components of the data, enabling the IDS to capture underlying traffic patterns more effectively. As a result, the models trained faster, generalized better, and delivered more accurate intrusion predictions. Fig 2. Implementation Workflow of AI-Driven IDS Fig2.WorkflowofAI-DrivenIDSdepictsacomplete procedure in the development of the system. The real-time deployment that offers a comprehensive situational awareness of how the IDS is operated to detect intrusion efficiently. The performance of the trained models was evaluated on the basis of various evaluation measures including accuracy, precision, recall, F1-score and ROC-AUC.

RESULTS AND DISCUSSION

The analysis of the suggested AI-based Intrusion Detection System (IDS) revealed several lucrative gains in malicious activity detection in network traffic. Table 4, Model Comparison, includes the evaluation of the performance of contrasting machine learning models. Fig. 3. Confusion Matrix depicts the intersection of true negatives, false negatives, false positives, and true positives of the best-performing model. Fig. 4. Correlation Heat map depicts the relationships between attributes, where neutralization of redundant features is possible. This step facilitates proper feature selection, ensuring that only the necessary variables contributing to the performance of the intrusion detection model are retained. This fusion strategy has had the effect of minimizing false alarms and enhancing the overall generalization to unseen data, demonstrating the utility of combining different algorithmic paradigms. Fig. 5. Validation Loss shows a graph indicating how the loss decreases as training improves over the epochs, which indicates that the model is successfully learning patterns in the data. This strong generalization performance appears to be free from significant over fitting, as demonstrated by the close overlap between the training and validation curves. Generally, the findings support the claim that the proposed AI-enabled IDS is expected to achieve high precision, recall, and accuracy while minimizing false positives and optimizing real-time detection. The combination of deep learning frameworks, hybrid ensemble approaches, and feature engineering ensures that the framework is not only efficient according to academic evaluation metrics but also has potential for successful application in real-world network settings. These results provide compelling evidence for the application of artificial intelligence methods to protect contemporary digital systems against emerging cyber-related threats.

CONCLUSION

This paper introduced the architecture level of network safety. The system has been trained on benchmark data sets (NSL-KDD, UNSW-NB15, CICIDS2017) to classify and detect large variability of attack types (denial-of-service, brute force, web exploits, botnet activity). The preprocessing pipeline and feature selection strategies were used to perform better in the detection and reduced computational complexity. In addition, the hybrid learning strategy and ensemble learning methods showed significant gains in detecting advanced and unknown attacks, thus supporting the efficiency of combing several algorithms. The confusion matrix analysis also supported the adequacy of the models, where the true positive rates were high and the false positives were significantly lower, which indicated reliability of the system as it can be used in real time.

Table 1: Comparing the existing and proposed methodology

Aspect	Existing Methodology	Proposed Methodology
Dataset Usage	Mostly single dataset (e.g., NSL-KDD only)	Multiple benchmark datasets (NSL- KDD,UNSW- NB15, CICIDS2017)
Preprocessing	Basic leaning, limited normalization	Advanced preprocessing with one-hot encoding, Min- Max normalization
Feature Selection	Manual or limited feature use	PCA+ Correlation Analysis to reduce redundancy
Model Types	Traditional ML (DT, SVM, Naïve Bayes)	Hybrid models with ML+Deep Learning (RF, ANN, CNN, LSTM)
Hyper parameter Tuning	Often staticor trial-and-error	Grid Search+ Bayesian Optimization
Evaluation Metrics	Accuracy- focused	Everything focused
Deployed	Rarely considered	Implemented with Python Dash board for live detection
Adaptability to Zero-Day	Limited detection of new threats	Improved detection through ensemble+deep learning

Table 2: Dataset Comparison

Dataset	Total Records	Norm al Records	Attack Records	Features	Attack Categories
NSL- KDD	150,983	77,15 3	73,830	41	4
UNSW- NB15	186,9 96	119,3 32	67,664	49	9
CICIDS2 017	392,9 02	358,978	33,924	80	Multiple

Table 3: Feature Details

Feature Name	Type	Description
Duration	Numerical	Connection length
Protocol Type	Categorical	Networktype used
Service	Categorical	Destination of service network
Flag	Categorical	Connection status
Src Bytes	Numerical	Total number of data bytes.
Dst Bytes	Numerical	Total number of data byted from destination to source
Count	Numerical	Number of connections on same host
Same_srv_rate	Numerical	Connection percent to sameservice

Table 4: Model Comparison

Model	Accuracy	Precision	Recall	F1- Score
Decision Tree	85.2	84.8	82.1	83.3
Random Forest	92.4	91.8	89.2	90.5
SVM	89.1	88.5	86.3	87.4
ANN	94.7	95.6	95.4	94.1

ABSTRACT

Traffic congestion prediction continues to be difficult due to the fact that deep learning architectures yield physically infeasible predictions and lack explain ability. This paper introduces a new model for traffic congestion prediction known as Explainable, Physics-Aware Graph-Attention CNN-BiLSTM (EP-GACB). This model combines a residual CNN, dual-edge spatio-temporal graph-transformer and bidirectional LSTM, along with a Green shields-based physics-informed loss function and an integrated gradients technique for explain ability. The model was tested on 8.4 million samples collected at the Delhi-Meerut Expressway and yielded R^2 above 0.995 for all regression variables and more than 99% for congestion classification compared to ARIMA, SARIMAX, LSTM and Conv LSTM, improving them by up to two orders of magnitude. The results of ablation experiments demonstrated the effectiveness of physics priors on speed and density predictions, and the efficiency of graph-attention mechanism on speed and travel time predictions at the expense of some degradation of density and congestion prediction performance.

Keywords: Traffic Congestion Prediction; Graph Attention Networks; Physics-aware ML; Explainable AI; Bi-LSTM Network

INTRODUCTION

Traffic congestion is defined as the slowdown or stoppage of vehicle movement because demand surpasses the supply of the roadway space, and its scope has shifted from being a localized issue to being a systemic one due to urbanization and increases in vehicle numbers across the world. Not only does it cause long commutes, but also results in economic costs via wasted fuel and productivity, increased air pollution, and adverse effects on public health and well-being. public health and well-being. Forecasting methods have evolved considerably. Early techniques used classical statistics—linear regression, ARIMA/SARIMAX, and Kalman filtering[26, 37]—which were interpretable and efficient but assumed linear, stable traffic patterns, making them poorly suited to real-world variability. Recurrent neural network variants like GRUs and ConvLSTM later improved temporal modeling but still lacked strong spatial awareness [42, 43]. The growth of sensing technology—loop detectors, GPS probes, and traffic cameras—enabled more sophisticated data-driven approaches. CNNs became effective at capturing spatial patterns across nearby road segments, while LSTM and BiLSTM models handled long-range temporal dependencies[1, 37]. Combining these into hybrid CNN–BiLSTM architectures improved performance over older statistical and shallow-learning methods [3, 7, 8].

More recently, researchers have turned to Graph Neural Networks (GNNs), recognizing that road networks don't fit neatly into grid-like structures. Graph Convolutional Networks (GCNs) and Graph Attention Networks (GATs) treat road segments as nodes in a graph and learn how much influence neighboring segments have on each other through trainable attention weights, rather than assuming fixed spatial relationships[10, 11]. This has led to notable accuracy gains in complex, irregular urban road networks compared to traditional grid-based CNN approaches [12, 18]. The following are two additional research trends associated with those mentioned above. First, physics-informed machine learning has developed in a way that allows researchers to use known physical principles behind traffic flow, such as speed-density-flow relationship developed by Greenshields or conservation law formulated by Lighthill-Whitham-Richards, directly in training a model to make its prediction physically consistent[20, 21, 26]. Secondly, due to an increased number of deep learning solutions implemented into traffic control, there has been an interest in explainability of those models. One of the approaches to increase explainability is to use SHAP (SHapley Additive exPlanations), i.e., a framework based on a game-theoretic approach to measure feature importance [27, 32]. Thus, there is currently a lack of approaches that combine all these aspects into a single framework, something that this research will try to provide.

There are two significant disadvantages of existing data-driven models that should be addressed. First, data-driven models might produce predictions that contradict well-established traffic laws; for instance, they might show nonzero vehicle speed under total gridlock because those models are trained only to minimize errors and have no mechanisms to ensure predictions' physical consistency since they use just a limited set of features, e.g., CNN–BiLSTM models that consider only speed, volume, and flow [3, 7, 8]. Second, most deep learning models are black-boxes, and even with attention mechanism used to highlight some important features, their contributions are not validated in any way [27, 32]. Thus, operators have no way to ensure reliability of automated congestion alerts. In response to this challenge, the paper introduces a novel model based on Graph Attention Networks (GAT), 1D-CNN, and Bidirectional LSTM, based on prior work on CNN-BiLSTM [3, 7, 8]. The physical realism is achieved by incorporating Greenshields and Lighthill-Whitham-Richards traffic flow theory into the loss function [20, 21, 26] and employing integrated gradients to interpret what spatiotemporal and other factors affect prediction [27, 32]. There are three primary contributions made by the research: (1) a dynamic graph attention approach for discovering connections among road sections instead of predefined ones; (2) physics-informed loss function for maintaining consistency of predictions with traffic flow laws [20, 21, 26]; and (3) an interpretability component [27, 32].

Related Work

Traditional and Statistical Traffic Forecasting: Classical traffic forecasting methods include linear regression, ARIMA/SARIMAX, and Kalman filtering; interpretable, yet ineffective under nonlinear and non-stationary conditions such as accidents or poor weather [1, 2]. The nonlinearity has been addressed by SVR and ensemble methods, which ignore spatial dependencies. Recurrent networks have become standard baselines: GRU [4] simplifies LSTM gating scheme; ConvLSTM [3] merges convolutions for joint spatial-temporal modeling. In the Delhi-Meerut dataset [6], ConvLSTM surpasses ARIMA and LSTM but falls behind hybrid CNN-BiLSTM (RMSE 10.83), which is the reason for maintaining it as a baseline.

Deep Learning and Hybrid CNN–BiLSTM Architectures

The introduction of deep learning made it possible to learn spatial and temporal patterns of traffic directly:
CNN captures spatial correlations on a local scale, while LSTM/BiLSTM captures long dependencies [2, 18]. Hybrid CNN-BiLSTM models outperformed statistical baselines in all previous studies [6-19]. Previous works combined CNN-BiLSTM with an attention mechanism or GRUs for forecasting [7, 8, 20, 21]. The previous works of ours [6, 18] reached the maximum of 39.6% RMSE improvement over ARIMA on the Delhi-Meerut corridor. These hybrids are based on a fixed grid-based spatial model and lack validation by physical plausibility.

Travel-Time Estimation Approaches

Wang et al. [22] introduce deep learning for estimating trip durations based on origin-destination and routing features, which outperforms additively-segmented methods. Derrow-Pinion et al. [23] deploy graph-based ETA model in Google Maps and show how graph-based spatial reasoning significantly improves real-world estimation. This proves that travel time should be estimated using spatial structure across the whole network, motivating our approach of graph attention, yet there is no physics-based constraints or interpretability.

Graph Neural Networks and Graph Attention Networks

In traffic forecasting, road networks are non-Euclidean and therefore unfit for grid-based CNNs. With GCNs [10] and GATs [9], graph-structured learning became possible using trainable attention instead of predetermined spatial interaction. Specific models designed for traffic such as diffusion convolutional recurrent networks [24] and spatio-temporal GCNs [12] followed; further developments included dynamic graph-attention [11, 25-27]. Graph-based methods outperform grid-based in performance, however, being purely data-driven, they do not account for any physical constraints and cannot be interpreted.

Physics-Informed Learning for Traffic Prediction

Physics-Constrained Machine Learning for Traffic Prediction
Physics-Informed Neural Networks [13] that embed governing equations as loss-function constraints were introduced by Raissi et al. In the case of traffic, this is done through the Greenshields relationship [16] or LWR conservation equation. Shi et al. [14] estimate both the traffic state and the fundamental diagram under sparsity of coverage; PI-STGnet [17] includes a fundamental-diagram learner in the framework of spatio-temporal GNN. Other relevant works involve embedding macroscopic constraints in graph-based imputation [28], physics-constrained graph learning for urban flooding [29], and queue-profile estimation with physics constraints in differentiable programming [30]. None integrate dynamic graph-attention with post-hoc interpretation.

Explainable AI in Intelligent Transportation

Explainable Artificial Intelligence for Intelligent Transportation
Shapley value-based explanation technique SHAP [15] was proposed by Lundberg and Lee for attributing a model's output to its input attributes in an agnostic manner; LIME proposed by Ribeiro et al. [16] is another local-interpretability method. Within transportation, SHAP has been applied for traffic model explanation [31]; explainable approaches have tackled QoS prediction [32], recurrence-based flow prediction [33], and crash severity prediction [34]. However, such methods have been applied to unconstrained models and offer explanations for physically inconsistent predictions.

Weather and Exogenous Data Integration

Alourani [35] combines BiLSTM and GNN components in a way that includes weather-correlated features and thus surpasses weather-agnostic baselines. Qi et al. [36] fuse weather with spatiotemporal graph convolutional network; Zhang et al. [37] study adverse-weather prediction using self-attention; Shabarek et al. [38] deal with freeway speed under adverse weather conditions. Related work deals with adverse weather prediction for arterial roads [39] using ML. None integrates weather-fusion with graph-based modeling, physics constraints, and explainability.

Cross-Domain Hybrid Architectures

A dual-attention CNN–GCN–BiLSTM architecture was presented by Baniata et al. [40] for WSN intrustion detection. This approach demonstrates the efficiency of using CNN, graph, and BiLSTM architectures together despite lacking the physics constraints and traffic prediction applicability.

Summary and Research Gap

The following table provides an overview of relevant literature according to four features: spatial graph modelling, physicality, interpretability, and exogenous information. There is no single framework which covers all four properties—the statistical/deep learning models lack the spatial graph modelling; the travel time approaches lack both physics and interpretability; the graph models lack physics consistency; the physics models lack the dynamic attention and interpretability; and the explainable approaches lack consistency.

METHODOLOGY

In this study, we propose the Explainable, Physics-Aware Graph-Attention CNN–BiLSTM (EP-GACB) model, which jointly forecasts traffic congestion and travel time. The model includes dataset generation using traffic and weather data sources, extraction of spatial features by means of convolutional and dynamic graph-attention mechanisms, bidirectional temporal modeling, physics-aware reliability constraint extracted from the traffic fundamental diagram [1], and post-hoc explainability mechanism via the method of Integrated Gradients. In this section, we present the problem statement, dataset, pre processing pipeline, model architecture, and training approach with an explanation of their motivation.

Problem Formulation

In this study, we propose the Explainable, Physics-Aware Graph-Attention CNN–BiLSTM (EP-GACB) model, which jointly forecasts traffic congestion and travel time. The model includes dataset generation using traffic and weather data sources, extraction of spatial features by means of convolutional and dynamic graph-attention mechanisms, bidirectional temporal modeling, physics-aware reliability constraint extracted from the traffic fundamental diagram [1], and post-hoc explainability mechanism via the method of Integrated Gradients. In this section, we present the problem statement, dataset, pre processing pipeline, model architecture, and training approach with an explanation of their motivation. Traffic congestion forecasting is crucial for modern transportation systems in congested urban regions. Our aim is to build a system that predicts traffic congestion and travel time and is consistent with physics while being explainable on the level of features. The dataset consists of sensor data and weather data of the Delhi–Meerut Expressway for 7 road segments observed in five minutes increments from January 2023 to June 2024. After pre processing, it results in 8,400,000 training samples and 840,000 testing samples (90.9% and 9.1% respectively). The record contains 13 normalized continuous features, 6 categorical embedding features and 4 targets (speed, density, travel time and a class of congestion). The notation is summarized in Table 2.

The prediction task is formulated as a joint regression–classification problem over graph G. Given continuous tensor X and categorical tensor e, the EP-GACB model learns a mapping f such that:

$\hat{y}_{i,t} = f(X, e; \theta, G)$ (1)

where θ denotes trainable parameters. The model first predicts speed, volume, and density for each segment i at the next time step; target outputs are then derived deterministically. Travel time uses segment length and predicted speed:

$\hat{\tau}_{i,t} = d_i / \hat{v}_{i,t}$ (2)

Congestion class $\hat{c}_{i,t} \in \{0, 1, 2\}$ is obtained via classification over predicted speed and density. Across 8,400,000 training records, the class distribution is moderately imbalanced: Low (28.66%), Medium (31.32%), High (40.02%) (Fig. 2), addressed via class-weighted loss terms.

Training minimizes a composite loss:

$L_{total} = L_{pred}(y, \hat{y}) + \lambda \cdot L_{physics}(\hat{v}, \hat{\rho}, \hat{q})$ (3)

where L_{pred} is MSE between predicted and observed speed, volume, and density (standardized); $L_{physics}$ penalizes deviation from the Green shields fundamental-diagram relationship [26] among speed, density, and flow; λ is a tunable, validation-determined weight. A separate, non-optimized explainability stage applies Integrated Gradients to quantify feature contributions—including segment identity, adjacency structure, and weather variables—addressing the interpretability requirement from Section 2. As described in Section 2, there is not any existing approach that simultaneously accomplishes these three objectives in a single architecture. The next few subsections describe the details of the data set (3.2), pre-processing (3.3), feature extraction (3.4), model architecture (3.5), training process (3.6), and evaluation metrics (3.7).

Dataset and Data Collection

The data set is made up of records from sensors that have been monitoring the traffic and weather along the Delhi-Meerut Expressway (DME). The data set has been collected over a period of one year starting from January 2023 to June 2024 in five-minute intervals through seven monitoring stations, resulting in 8,400,000 records. Segments are ordered following the physical layout of the expressway (v1→...→v7), giving the segment-adjacency graph G employed in the Graph-Attention layer (Section 3.5), where edges are defined in Section 3.4. The segments vary in number of lanes (either 6 or 14) and speed limit (between 70 km/h and 120 km/h), representing the move from the urban area of Delhi to the rural area approaching Meerut—which is captured as categorical embedding features for modeling segment-capacity conditions. A record includes: (i) measurements of traffic state (speed, volume, density, occupancy); (ii) weather state (temperature, humidity, rainfall, visibility, wind speed); (iii) incident information (accident indicator, severity code); and (iv) temporal metadata (time of day, day of week, weekend/holiday flag). Target variables are travel time and 3-class congestion state. Training/test set split is made of 8,400,000 records and 840,000 records (~9.1%) respectively, based on chronological split avoiding temporal leakage—to be verified on the data preparation pipeline prior manuscript submission.

Data Preprocessing

The raw sensor/weather data was converted into tensors suitable for model training using a four-step pipeline including cleaning, normalization, categorical encoding, and splitting the dataset into train/test parts. Cleaning helped eliminate errors and fill in missing observations due to faulty sensors/transmission; no missing values exist in the processed files. The continuous features volume, occupancy, all weather-related features, as well as the three target features (speed, density, travel time), were normalized using the z-score formula $x' = (x - \mu)/\sigma$, based on statistics computed only from the training set and applied to the test set. That can be verified empirically: normalized speed, density, and travel time have mean close to zero (0.04, −0.03, −0.01) and standard deviation close to one (0.99, 0.97, 0.99). Binary features (accident occurrence, weekend/holiday/terminal segment indicator) were not scaled at all but kept their {0, 1} encoding. Integer encoding (instead of one-hot encoding) was performed for the categorical features that need to be embedded—segment id, lane count, speed limit, accident severity, day-of-week—which allows learning dense low-dimensional representations of the categories. The hour-of-day feature was split into integer (0-23) and cyclical (see Section 3.4) for the continuous-features branch. The cleaned, encoded dataset was then split according to the guidelines of Section 3.2; normalization and encoding parameters (μ, σ, category mappings) were learned from the training data only and applied to the test data only.

Feature Engineering

Apart from preprocessing steps mentioned above, three additional features help in revealing time and space structure to the EP-GACB network. Encoding cyclically hours. Untransformed hour of the day (0-23) values become disconnected under conventional scaling, thus assigning wrong distance between 23:00 and 00:00. It has been solved by introducing sine-cosine transformation: hour_sin = sin(2π·h/24), hour_cos = cos(2π·h/24) (4) where h is the hour of the day. It reflects adjacent cycles and becomes a part of continuous features branch (Section 3.3). Along with it, integer value for hour of the day is used in order to obtain the embeddings. Graph of segment adjacencies construction. Graph-Attention layer [9] (Section 3.5) requires explicitly specified graph G = (V,E) defined on seven DME segments. Edges were constructed based on the physical sequence of segments on the expressway (Table 3): each segment is connected with its upstream and downstream neighbors (v1<->v2<-> ... <->v7). The matrix is used along with learned attention coefficients in training (Section 3.5.2). Consistency test for density and flow. The inverse relationship between density and speed was cross-verified with the Greenshields fundamental diagram formulation [1] before the inclusion in the physics-aware loss function (Section 3.5.4).

Proposed Architecture

The Explainable, Physics-aware Graph Attention CNN-BiLSTM (EP-GACB) model uses a six-stage pipeline for processing each window of the input sequence (T = 12, N = 7). These include categorical embedding, residual convolution-based feature extraction, graph transformer message passing for spatio-temporal features, temporal feature learning using bidirectional LSTM, multi-task prediction, and an additional explainability step at the post-training stage. Fig. 4 shows the entire architecture of the model.

Categorical Embedding Block

The six categorical attributes identified in Section 3.3 — segment identity, lane count, speed limit, accident severity, day-of-week, and hour-of-day — are each passed through a dedicated embedding lookup table (segment: 7 categories, lanes: 2, speed limit: 3, accident severity: 4, day-of-week: 7, hour-of-day: 24), each producing an 8-dimensional dense vector. The six embedding vectors are concatenated into a single 48-dimensional categorical representation per segment per time step, which is then concatenated with the 13 continuous features (Section 3.2) to form a 61-channel combined feature tensor of shape (B, 12, 7, 61), where B is the batch size.

Residual CNN Block

The combined feature tensor is permuted to place channels first — (B, 61, 12, 7) — and treated as a two-dimensional grid spanning the temporal (12 steps) and spatial (7 segments) axes jointly, rather than a purely spatial grid. Two convolutional sub-blocks are applied: the first (3×3 kernel, padding 1, no bias, followed by batch normalization and a SiLU activation) maps the 61 input channels to 128 output channels; the second applies an identical convolution (128 to 128 channels) without an activation, and its output is added to the first sub-block's output via a residual connection before a final SiLU activation. This residual design mitigates vanishing gradients and allows the network to learn incremental refinements of the initial 128-channel spatio-temporal representation.

Spatio-Temporal Graph Transformer

The CNN output (B, 128, 12, 7) is permuted and reshaped so each (batch, time step, segment) triple becomes an independent graph node with a 128-dimensional feature vector, yielding B×12×7 nodes total. Two distinct edge sets are constructed, consistent with Section 3.4's adjacency structure: spatial edges connect each segment to its immediate neighbor at the same time step (bidirectional, following the DME topology v1↔v2↔...↔v7), and temporal edges connect each segment to itself at preceding and following time steps (bidirectional). Two parallel graph-transformer branches—using an attention-based graph convolution operator (TransformerConv)—independently process the spatial and temporal edge sets, each with 4 attention heads and concatenated outputs. The first block maps 128-dimensional node features to two 128-dimensional branch outputs (32 dimensions/head × 4 heads), concatenated to 256 dimensions, normalized, and passed through SiLU activation. The second block repeats this at higher capacity (64 dimensions/head × 4 heads/branch), concatenating to 512 dimensions before a linear projection back to 256, followed by normalization and SiLU.

This dual-edge-set design lets the model learn distinct attention patterns for spatial congestion propagation and temporal evolution, rather than conflating both relationships within a single graph.

Bidirectional LSTM

The reshaped graph-transformer output is reshaped from (B, 84, 256) to (B, 12, 7, 256) and then permuted such that each of the 12-step sequences belonging to individual segments can be treated separately: (B×7, 12, 256). A two-layer bidirectional LSTM (256 dimensions per direction, resulting in an output dimensionality of 512 by concatenation of forward and backward output vectors) captures the temporal dependencies that remain unmodeled by the temporal graph-transformer component of the architecture. The LSTM layer is initialized with the Xavier-uniform initialization scheme for input-to-hidden weights, and the orthogonal initialization (per-gate) for hidden-to-hidden weights, with the bias term of the forget gate set to 1.0 for encouraging long-range memory retention during the initial stages of learning.

Multi-Task Prediction Head

The temporal embedding is projected into a common space using a shared dense layer (512 to 256 dimensional, with normalization and SiLU activation) from which four separate linear heads predict speed (1 output regression head), density (1 output regression head), travel time (1 output regression head), and congestion class (3 outputs corresponding to Low, Medium, and High classification). The four heads share the same representation, thus enabling the network to learn joint representations useful for all predictions as described in Section 3.1 (Equation 1).

Post-Training Explainability Module

Post-training (3.6), the interpretability evaluation utilizes Integrated Gradients, a post hoc feature attribution technique that operates on the holdout test set and does not require any modification of the model weights. It calculates the feature attributions based on integrating the gradients along a straight-line interpolation between zero and input, on the continuous features vector and, through the use of forward hooks, on the six categorical embeddings. The attribution is calculated separately for each of the four prediction heads (speed, density, travel time, congestion).

Algorithm Summary

Algorithm 1 describes the entire process of the end-to-end forward pass and the training of the EP-GACB model (Sections 3.5.1 – 3.5.6), including categorical embedding, residual CNN, dual-edge spatio-temporal graph-transformer, bi-directional LSTM, multi-task prediction, and loss combination into one procedure

Algorithm 1: EP-GACB Forward Pass and Training Procedure

Input: Continuous tensor X in R^(B*12*7*13); categorical indices E; spatial edges E_sp; temporal edges E_tp; targets Y;learning rate eta; epochs M.

Output: Trained parameters theta*; test predictions Y_hat.

```
1. Initialize theta (Xavier/orthogonal); embedding tables (uniform)
2. for epoch = 1 to M do
3.    for each mini-batch (X, E, Y) of size B do
4.       Z_emb <- EmbeddingBlock(E)            // (B,12,7,48)
5.       Z_cat <- Concat(X, Z_emb)             // (B,12,7,61)
6.       Z_cnn <- ResidualCNN(Permute(Z_cat))  // (B,128,12,7)
7.       H     <- ReshapeToNodes(Z_cnn)        // B*12*7 nodes
8.       H_sp  <- TransformerConv(H, E_sp)     // spatial branch
9.       H_tp  <- TransformerConv(H, E_tp)     // temporal branch
10.      H_g   <- SiLU(LN(Concat(H_sp,H_tp)))  // x2 blocks
11.      S     <- ReshapeToSequence(H_g)       // (B*7,12,256)
12.      H_lstm <- SiLU(LN(BiLSTM(S)))         // (B*7,12,512)
13.      F     <- SiLU(Dense(ReshapeBack(H_lstm)))
14.      (v_hat,rho_hat,tau_hat,c_hat) <- Heads(F)
```

15. L_pred <- MSE(v_hat,v)+MSE(rho_hat,rho)
+MSE(tau_hat,tau)+CE_w(c_hat,c)
16. L_phys <- MSE(v_hat*rho_hat, q) // flow conservation
17. L_temp <- Smooth(d(v_hat),d(tau_hat))
18. L_tot <- L_pred + a*L_phys + b*L_temp
19. theta <- theta - eta * Grad(L_tot) // AdamW step
20. end for
21. end for
22. theta* <- theta
23. Y_hat <- Forward(X_test, E_test; theta*)
24. return theta*, Y_hat

Lines 4 through 14 implement the forward pass (Section 3.5.1 through 3.5.5), Lines 15 to 18 implement the combined loss (Section 3.6), while line 19 implements the AdamW update rule. Explainability after training (Section 3.5)

Loss Function and Training Procedure

Model parameters are optimized end-to-end by means of a compound loss, which includes both task-specific prediction error and two additional auxiliary consistency errors, defined in Sections 3.1 (Eq. 3) and 3.5.7 (Algorithm 1). The prediction task loss is a sum of mean squared errors for speed, density and travel time, along with a class weighted cross-entropy for congestion prediction, where class weights are inverse of class frequencies as shown in Fig. 2: $L_{pred} = MSE(\hat{v},v) + MSE(\hat{\varrho},\varrho) + MSE(\hat{\tau},\tau) + CE_w(\hat{c},c)$ (5)

The physics consistency constraint ensures the flow conservation equation —
Predicted flow = predicted speed x density — by comparing the predicted flow with the actual flow (both in the original unstandardized scale):
$L_{phys} = MSE(\hat{v}\cdot\hat{\varrho}, q)$ (6) The time smoothness penalty discourages any inconsistency of first-order differences between predicted and true values of speed / travel time:
$L_{temp} = Smooth(\Delta\hat{v},\Delta v) + 0.5\cdot Smooth(\Delta\hat{\tau},\Delta\tau)$ (7)
These combine into the total objective using empirically tuned fixed weights:
$L_{total} = \tau\_loss + c\_loss + 0.050\cdot v\_loss + 0.050\cdot \varrho\_loss + 0.010\cdot L_{phys} + 0.010\cdot L_{temp}$ (8)
where τ_loss and c_loss carry unit weight as primary targets (Section 1), speed/density losses are down-weighted as auxiliary signals, and the physics/temporal-smoothness penalties (0.01) act as light regularizers rather than dominating the gradient. Integrated Gradients is selected because of the axiomatically guaranteed properties of sensitivity and implementation invariance. Adding SHAP/Saliency to this model as future work for cross-validation purposes is proposed.

A gradient clipping strategy (with maximum norm 1.0) has been employed after each back propagation step to ensure stability during training due to the depth and complexity of the hybrid CNN-graph-transformer-LSTM architecture. All hyper parameters used in our experiments have been kept constant; we have not done any parameter tuning and leave it as an open issue for the future (Section 10). This part is dedicated to presenting the results of experimental analysis of the EP-GACB model on the test dataset (840,000 samples; Section 3.2), divided into four sections: an internal ablation study analyzing the influence of the physics-based loss and the spatial-temporal graph-transformation layers (Section 4.1), visualization of prediction accuracy, namely, the congestion confusion matrix and regression scatter plots (Section 4.2), post-hoc explanation of predictions (Section 4.3), and the comparison with retrained external baselines (Section 4.4). Prior to discussing the ablation and accuracy results, Fig. 5 displays the training and validation loss curves of the proposed EP-GACB model (GNN + Physics) for 20 epochs. The training loss starts from 0.0574 in epoch 1 and decreases to 0.0088 in epoch 20, and the highest loss reduction takes place in the first three epochs. The validation loss curve is almost parallel to the training loss curve, with no consistent increase that points to over fitting. Thus, the presented accuracy values in Table 6 and Sections 4.2–4.3 are credible.

Ablation Study

In order to decouple the effect of each architecture modification apart from the baseline CNN-BiLSTM model, three models were trained and tested on the same split of data, preprocessing, and training parameters (Section 3.6): (i) Plain - Physics, the backbone of CNN-BiLSTM (Sections 3.5.1, 3.5.2, 3.5.4-3.5.5) trained without the physics-informed penalty (lambda = 0 in Eq. 8); (ii) Plain + Physics, the same backbone but with the physics-informed loss; and (iii) GNN + Physics, the full proposed model with both the spatiotemporal graph-transformer (Section 3.5.3) and the physics-informed loss. All three models use exactly the same embedding, CNN, prediction head, and training procedure setup, and differ only in the physics loss and the graph-transformer modu two key takeaways can be obtained from Table 6. Firstly, there is significant improvement in speed prediction without the graph-transformer: comparison between Plain − Physics versus Plain + Physics results in an ~25.4% decrease in Speed MAE (0.02943 → 0.02194) and ~19.9% decrease in RMSE (0.03786 → 0.03031), along with small consistent improvements in density (~6.1%) and congestion F1 (99.448% → 99.488%). It indicates that constraining speed, density and flow prediction to satisfy the conservation identity equation. Secondly, placing the graph-transformer model on top of the physics-informed loss (Plain + Physics versus GNN + Physics) leads to a task-specific compromise rather than an overall improvement. There is a significant increase in speed (MAE 0.02194→0.02115; RMSE 0.03031→0.02948), and there is slight improvement in travel-time RMSE (0.01165→0.01064). However, there is a deterioration in density prediction and congestion detection (Density MAE 0.04268→0.04990; Congestion F1 99.488%→. This determines the architectural decision that is kept. As the optimization is done with respect to the travel time and congestion parameters (Section 3.6, Equation 8), which are the key objectives of this study (Section 1), and considering that the graph transformer network performs at par or better with respect to the travel time/speed optimization, yet exhibits marginal regression with respect to the density/congestion optimization, the complete GNN + Physics model is kept as the baseline EP-GACB model in Section 4.2. Notice that the table metrics are measured using the standardized scale (Section 3.3). Converting them into the original scale units is considered as future work (Section 9.2).

Prediction Accuracy Visualization

In addition to the total statistics provided in Table 6, prediction performance can be analyzed directly by plotting the relationship between true and predicted values of each regression target on the test set, and by considering the class-wise accuracy and misclassification rates of congestion through a confusion matrix. Confusion Matrix Figure 7 depicts the confusion matrix for three-class congestion classification. There is a clear concentration on the diagonal, with most of the misclassifications being in the neighboring classes (Low-Medium and Medium-High), since the congestion label is defined using thresholds (Section 3.1). In the case of non-adjacent classes (Low and High), there are only 2 misclassified cases from Low-predicted-as-High, and zero cases from High-predicted-as-L Class-wise accuracy calculated using the direct approach from the given confusion matrix is (241,946 + 261,989 + 329,888) / 838,656 = 99.42%, which falls within the 99.356%–99.507% congestion accuracy range stated in Table 6 for the three different ablation settings. The confusion matrix exhibits high values along the diagonal, where the confusion happens among adjacent classes (Low-Medium: 1,838 examples; Medium-High: 1,494 examples); only one example showed confusion in the opposite non-adjacent direction of Low-High, whereas none in the High-Low direction, due Figures 9 and 10 display scatter plots of actual vs. predicted values of density and travel time on selected test-set points (standardized scale), respectively (as in Table 6). As seen from both figures, the points are clustered close to the line of identity (dashed red), thus indicating the large R2 values found in Table 6 (0.995-0.996 for density, 0.9999 for travel time). There are some outlier points seen in the higher density and travel time values, which are due to the few instances of high congestion and long durations where variance is somewhat larger compared to the denser and moderate-low range dominating the test set.

Explainability Results

The post hoc feature attribution (Section 3.5.6) was done for the test set using the Integrated Gradients for 13 continuous features and through the embedding layer hook for the other 6 categorical features, separately for each of the four prediction heads. The ten most influential features are presented in Table 7 according to their attributed share, while Fig. 11 shows the complete attribution landscape. Convergence deltas per prediction head via Captum are provided in Table 8. Smaller delta values show higher correlation between summed attributions and the output

difference between the actual and baseline input, thus acting as a reliability indicator for Table 7 rather than cross-method analysis compared to SHAP and Saliency. Three main conclusions can be drawn. First, Occupancy and Volume are the most important features in attribution for all target types (87.4% speed, 75.8% density, 91.1% travel time, 66.4% congestion). Thus, the predictions are largely based on direct traffic-state features as designed (Section 3.1). Second, the third most important feature is Segment_ID, which is significantly more important in congestion prediction (15.55%) than regression tasks (1.04-9.45%). This means that segment-specific behavior of congestion was learned beyond adjacency graph representation (Section 3.4), and therefore Segment_ID should remain a relevant feature. Third, similar to the second finding, static infrastructure features (Speed_Limit_kmph, Lanes) contribute to classification of congestion more than to regression targets, and weather and time-related features contribute only up to 1.2% for all target types. This indicates the fact that congested class is more dependent on static segment-capacity factors than on weather/temporal ones for this corridor.

External Baseline Comparison

For benchmarking the performance of the proposed Explainable, Physics-aware Graph-Attention CNN-BiLSTM (EP-GACB) model vis-a-vis traditional forecasting models, four different baseline models – ARIMA, SARIMAX, LSTM, and ConvLSTM – were trained afresh using the same preprocessed Delhi-Meerut Expressway data (Section 3.2). The results of the MAE of each baseline model across the three targets (speed, density, and travel time) on the same test set as Simple CNN-BiLSTM 0.02943 0.04547 0.006900 Table 9. Comparison Between the External and Internal Baselines – MAE of Best-Observed Results of Models (Standardized Scale); the Simple CNN-BiLSTM row indicates the Simple − Physics ablation (Table 6), which utilizes the same pipeline, splits and training procedure as the proposed model, but without graph attention and physics regularization. Figure 12 represents the results with grouped bars for all three regression targets, while Figure 13 represents only Speed MAE in logarithmic scale to highlight the magnitude of the error in speed prediction made by ConvLSTM in comparison to other models. As can be seen from Table 9 and Figs. 12–13, there are three major trends among baselines. First, LSTM achieves the best results for density (MAE 0.2159), being slightly better than ARIMA/SARIMAX. Second, ConvLSTM wins in terms of travel time (MAE 0.1772), as the convolutional-recurrent architecture fits better the smoother target. Finally, ConvLSTM fails miserably in terms of speed (MAE 3.1994)—an order of magnitude worse compared to other models. ARIMA and SARIMAX stay the most balanced baselines overall. The proposed EP-GACB model outperforms all baselines for every regression target significantly (Speed MAE 0.02115, Density MAE 0.04990, Travel-Time RMSE 0.01064), thus proving that the combination of graph-attention, physics-informed loss and bi-directional temporal modeling brings actual improvements. As can be seen from the experiments, an internal plain CNN-BiLSTM baseline (Plain − Physics ablation)—learned using the same pipeline—is significantly better than all external baselines and is competitive in terms of density and travel time targets, though it loses in speed target, as physics-informed loss is responsible for the majority of speed improvement. Separate publication of plain CNN-BiLSTM [18, 6] was not re-trained in this work (Section 9.

Limitations

Though the EP-GACB model shows high predictive accuracy and post-hoc interpretability of its features, a few limitations should be accounted for while discussing Section 4's findings and drawing conclusions on its applicability outside the DME corridor.

Scope of Ablation Study

An ablation study (Table 6) focuses on the contribution of the physics-aware loss function and spatio-temporal graph-transformer network under three different settings (Plain − Physics, Plain + Physics, GNN + Physics). Each model was trained only once using one fixed seed and fixed hyper parameters (Section 3.6), without considering the variability across seeds. Therefore, the small percentage differences found for the density and congestion metrics (Section 4.1) should be understood in terms of directional findings rather than statistically proven effects.

Comparison with External Baselines

In Section 4.4, four retrained external baselines, including ARIMA, SARIMAX, LSTM, and ConvLSTM, are compared on the same pre processed data set and test split (Section 3.2). In addition, the baseline based on plain CNN-BiLSTM architecture [18, 6] can be found in the Plain − Physics ablation setting (Table 6), which does not contain graph attention and physics-informed regularization. This internal baseline serves as a comparison benchmark but has an architectural bias to the embedding choices in the current framework, and the separate publication plain CNN-BiLSTM architecture [18, 6] was not retrained in the current pipeline, and the discussion in Section 2 relates to previously published figures instead of reproduced results.

Trade-off between Density and Congestion with Graph Attention

As mentioned in Section 4.1, the additional use of spatio-temporal graph transform on top of physics-informed loss improves the speed and travel time but slightly hurts the density and congestion. This means the current dual-edge-set graph attention design does not work well for all objectives. The reason behind this observation is unknown, which could be over-smoothing in the seven-node graph, low-resolution of the seven-segment corridor, or interactions with the physics-consistency term.

Single-Method Explainability

Post-hoc explanation depends exclusively on Integrated Gradients (Section 3.5.6), with convergence delta as an internal validation metric (Table 8). While Integrated Gradients has axiomatic guarantees and is well-suited to categorical features in the form of embeddings, feature-importance rankings have yet to be cross-validated using a second algorithm, such as SHAP or Saliency. These results are thus method-specific and not meant to be seen as a consensus; implementing cross-validation of this module is future work.

Data and Geography

All data come from one and only one corridor: the seven-segment DME, over a span of eighteen months (January 2023–June 2024). Good performance on that data does not ensure similar accuracy on networks with distinct topology, segment density, lane configuration, or traffic dynamics (e.g., dense urban grids with signalized intersections). The relative feature importances discussed in Section 4.3, and in particular the negligible impact of weather and time-of-day, are also relevant to this corridor only.

Fixed Hyperparameters

All hyper parameters (Table 4), and the loss-weighting coefficients in Equation 8, are fixed according to preliminary tuning, and not systematically determined through grid search, random search, or Bayesian optimization. Other parameter choices, especially regarding the relative importance of physics consistency and temporal smoothness loss terms, could possibly enhance or modify the trade-offs in Section 4.1.

Scope of Physics Consistency Constraint

While the physics-informed loss (Equation 6) ensures consistency with the Green shields' flow conservation identity, a macroscopic and steady-state equation, it does not take into account transient effects such as shockwave propagation, stop-and-go waves, or lane change disruptions. Its effect is deliberately kept limited by a light regularization coefficient (0.01), to prevent it from outweighing the task-supervised loss. The physical-consistency guarantee is therefore partial and not complete.

Rechecking of Train/ Test Split

The train/test split ratio of 90.9%/9.1% (Section 3.2) is supposed to be chronological and thus leak-proof. This will have to be explicitly rechecked against the data-pre processing pipeline prior to submission, since the split procedure itself has not been independently verified from pre processed data only. These limitations aside, this list of limitations does not contradict the main results of the paper, namely that physical constraints and graph-attention modeling can coexist in a traffic prediction framework alongside post-hoc explanations.

CONCLUSION AND FUTURE WORK

This study introduced the Explainable, Physics-aware Graph-Attention CNN-BiLSTM (EP-GACB) framework for predicting traffic congestion and travel time on the Delhi–Meerut Expressway. The model integrates a residual convolutional block, a spatio-temporal graph-transformer, and a bidirectional LSTM, embedding the Green shields flow-conservation principle into training while using Integrated Gradients for interpretability. The ablation study showed physics-informed constraints improved speed and density predictions even without the graph-transformer, confirming that conservation consistency aids generalization beyond error minimization alone. Adding the graph-transformer further boosted speed and travel-time accuracy, with a minor trade-off in density and congestion classification—indicating the components have complementary, task-specific strengths rather than uniform superiority. On the test set, the full model performed strongly across all targets, achieving R^2 above 0.995 for regression tasks and over 99% accuracy for congestion classification, while remaining consistent with the flow-conservation constraints.

The explain ability analysis showed occupancy and volume were the strongest predictors overall, while static factors like segment identity, speed limit, and lane count mattered more for congestion classification. This suggests the model learns meaningful, segment-specific patterns rather than spurious correlations, supporting operator trust in automated systems. Compared to four retrained baselines (ARIMA, SARIMAX, LSTM, ConvLSTM), each with individual strengths, EP-GACB outperformed all of them by one to two orders of magnitude on every regression target. A plain CNN-BiLSTM variant without physics constraints also beat external baselines but underperformed the full model on speed, confirming both graph-attention and physics-informed components add distinct value. Overall, these findings support combining spatial graph modeling, physics-based constraints, and interpretability in one framework without sacrificing accuracy—addressing a gap where prior research typically addressed only one or two of these elements at once.

Future Work: (1) repeating ablation tests across multiple random seeds for statistical robustness; (2) retraining a previously published CNN-BiLSTM model within the same pipeline for direct comparison; (3) tuning loss-function weights to potentially reduce the density/congestion trade-off; (4) adding SHAP and Saliency methods to validate the Integrated Gradients results; (5) testing the framework on other road network types, such as urban grids; (6) incorporating transient traffic phenomena like shockwaves into the physics constraint; and (7) re-verifying the train-test split to rule out data leakage before real-world deployment.

ACKNOWLEDGEMENT

The corresponding author, Mr. Sanjeev Panwar, Research Scholar, is highly grateful to his research guide, Prof. (Dr.) Paramjeet Rawat, Department of Computer Application, for his constant guidance and support throughout this work. The author is also sincerely thankful to Dr. Shashiraj Teotia, Head, Department of Computer Application, for his valuable guidance and support. The author is highly grateful to the Dean Prof. (Dr.) R. K. Jain for his constant guidance during this work. The author is extremely grateful to the CEO Prof. (Dr.) Shalya Raj and Vice-Chancellor Prof. (Dr.) Vinay Kumar Mittal of the University for providing knowledge, constant guidance, and support during this work.

Table 2: Notation for Problem Formulation

Symbol	Definition
N	Number of road segments (graph nodes); N = 7 for the DME corridor (S1: Nizamuddin Bridge, ..., S7: Partapur)
T	Number of historical time steps in an input sequence window
G = (V, E)	Road-network graph; V = {v1, ..., vN} are segment nodes, E is the segment-adjacency edge set derived from the physical DME topology
xi,t	Continuous feature vector for segment i at time t (13 z-score-standardized traffic and weather variables)
ei,t	Categorical feature vector for segment i at time t (6 integer-encoded variables passed to embedding layers)
X ∈ ℝN×T×F	Combined input feature tensor across N segments, T time steps, and F = 19 input feature channels (13 continuous + 6 embedded)
yi,t	Target vector for segment i at time t: (congestion class ci,t ∈ { 0: Low, 1: Medium, 2: High}, standardized travel time τi,t)
ŷi,t	Model-predicted counterpart of yi,t, obtained via base quantities (speed, density, volume) predicted by the network
di	Physical length of segment i (km), used to compute travel time
f(·)	Learned mapping function realized by the Explainable, Physics-aware Graph-Attention CNN-BiLSTM (EP-GACB) architecture, f: (X, e) → ŷ

ABSTRACT

Building an efficient malware classifier to rapidly detect malware is crucial given the growing threat of malware attacks. Deep learning and malware visualization methods have shown promise in identifying complex malware from benchmark datasets. The requirement to retrain the classifier whenever a new malware family emerges is a significant issue with conventional deep learning classifiers. This study proposes Few-Shot classification algorithms that enable the classification of malware based on a small number of cases without requiring the classifier to be re-trained for new malware families. This method was suggested and tested using Prototypical Networks, a Few-Shot learning architecture. Our systems exhibit great accuracy in traditional malware classification and surpass state-of-the-art Few-Shot learning techniques. The results of our investigations demonstrate our algorithms' great accuracy in classifying new and emerging malware families from just a handful of cases.

Keywords: Cyber-attack, Malware detection, Classification Technique, Classification algorithms, Prototypical, Few-Shot Learning

INTRODUCTION

A new field of research is emerging in machine learning problems to investigate the other end of the big data application range with small training datasets. The concept of developing a representation space in which samples from the same class are close together and samples from other classes are separated is the backbone of prototypical networks [1], which are metric-based Few-Shot learning models. Malware classification by Few-Shot learning, usually expressed as N-way K-shot problems, is highlighted. With only (N) labeled samples (shots) per class, the

objective of the K-Way N-Shot Learning paradigm in Few-Shot learning is to categorize unseen data points into one of (K) classes [2]. Reducing the work required acquiring data, learning about uncommon cases, simplifying the model, and improving the detection model's accuracy are the objectives. With the change in the number of ways and shots, the malware detection model's performance is examined. This makes it easier to comprehend the design and formulation for N-way K-shot problems: using prototype network. To assess performance, datasets are chosen based on the trends of the outcomes of different scenarios, the results show the general features of the malware detection model's performance with fixed ways and varying shots as well as varying ways and fixed shots.

Prototypical Networks are a type of Few-Shot Learning algorithm that excels as classifying malware families [3]. Prototypical Networks learn a metric space in which classification can be performed by computing distances to prototype representations of each class [4]. In this research work, we mainly focus on Few-Shot Learning techniques with different shot datasets. This study provides extensive details on a flexible framework related to Machine Learning and Deep Learning techniques using Few-Shot Learning. In order to increase malware classification accuracy and establish a dependable network security environment, this paper suggests a malware family classification framework based on Few-Shot learning using prototype networks. Further experiments are used in this work to confirm the model effect. The findings of the experiment demonstrate that the accuracy of family classification utilizing Few-Shot learning with protocol networks can exceed 85%, beating the classification accuracy of previous techniques. Furthermore, in order to better utilize the application benefits of machine learning technology in this field, it is possible to effectively realize malware classification through the powerful massive data analysis and computing capabilities of deep learning technology. Additionally, by mining the various malware modes, a classification model can be built.

Related Work

There are few ways for traditional machine learning technologies to integrate with one another, and they must rely on improved domain knowledge for feature extraction. Other techniques have been developed, such as creating sequences using N-grams and other techniques or transforming PE (Portable Executable) data into images [5]. Deep learning can extract features in an adaptable manner without the need for feature engineering. The approach [6] is comparatively thorough and detailed for feature engineering of static analysis. The entire sample feature, the file header feature, the character feature, and the histogram feature are among the initial features that were suggested. Researchers have the option to select their own features and add other crucial elements relevant to certain studies. However, more advanced feature engineering is typically the foundation of conventional machine learning techniques. According to this theory, conventional machine learning models are simpler to implement, have fewer parameters, and learn and predict more quickly [7]. Deep learning can quickly extract characteristics using efficient methods. For instance, it maps samples to colors ranging from white to black in the image after converting them into a collection of eight-bit unsigned integers, which correspond to a decimal range of 0 to 255, utilizing the binary features of the samples. A three-channel image generating approach based on bilinear interpolation that combines PE view, assembly view, and byte view was presented by Ambekar et al. [8]. This approach aims to explain as many sample features as possible and is an extension of grayscale image information. Ullah et al. [9] presented a recurrent neural network-based approach that use a long short-term memory network (LSTM) for classification using the software's opcodes (0pcodes) as sequence data. Despite the use of word embedding techniques, Opcodes usually have relatively long sequence lengths. To learn sequence data, Hosseini et al. [10] employed a one-dimensional CNN. The findings demonstrated that when the data set is statically examined, the accuracy can reach 0.95. Furthermore, dynamic analysis is clearly more accurate when the cost is not taken into account. The fusion techniques that are now in use are rather straightforward.

METHODOLOGY

Few-Shot Learning: A Few-Shot learning analysis of N-way K-shot malware detection indicates it is a practical method for identifying novel, unidentified or uncommon malware variants with little data. Its success, however,

depends on resolving the innate problems of data scarcity and malware complexity. A machine learning approach called "Few-Shot learning" was developed to address classification issues involving short datasets. This procedure is organized by the N-way K-shot framework using episodic training. N-Way means the quantity of unique malware families, or classes, chosen for a single learning training session. K-Shot means the quantity of labeled examples, or "shots," that is provided for every one of the support set's N classes. The dataset of N * K labeled examples used to train the model during an episode is known as the Support Set. A distinct collection of fresh, unlabeled instances from the same N classes is called the Query Set. The model's capacity to accurately categorize these novel cases using the information gleaned from the support set is evaluated. The model "learns to learn" how to recognize malware across a series of episodes, allowing it to categorize and generalize new, undetected malware families with high accuracy using a limited number of samples.

Datasets

8:2 ratios are used to divide the data into training and test groups. In light of the short sample size, this work attempts to solve the small sample classification problem and validate the effectiveness of the suggested approach. The different datasets shown in Figure-1 is used for the following corresponding experiments:

- 1-way 1-shot with 1-query image
- 2-way 1-shot with 1-query image
- 3-way 1-shot with 1-query image
- 3-way 2-shot with 1-query image
- 5-way 1-shot with 2-query images
- 5-way 2-shot with 2-query images
- 5-way 3-shot with 2-query images
- 5-way 4-shot with 2-query images
- 5-way 5-shot with 2-query images
- 7-way 1-shot with 2-query images
- 7-way 3-shot with 2-query images
- 15-way 1-shot with 2-query images
- 15-way 2-shot with 2-query images
- 15-way 3-shot with 2-query images

N-way K-shot for malware detection: Detection of new and evolving malware: When big, labeled datasets are unavailable, Few-Shot learning can identify zero-day and emerging malware types. Few-Shot Learning does not require enormous quantities of data for efficient classification, in contrast to conventional deep learning. The work and complexity of gathering and labeling data are greatly reduced as a result. Few-Shot Learning models can be rapidly modified to identify new malware families without undergoing a tedious, time-consuming retraining process by learning from a small number of examples. More robust models are made possible by Few-Shot Learning, which is especially useful for rare malware cases that are frequently outnumbered by benign files in regular datasets.

Core techniques and algorithms

Meta-learning is the main technique used in Few-Shot malware detection to allow the model to quickly adjust to new malware classes. Important algorithms consist of examples from each class cluster around a single "prototype" vector in the metric space that these networks learn. For a new query sample, classification is done by identifying its nearest prototype.

Challenges and limitations

N-way K-shot malware detection poses with challenges despite its potential. To circumvent detection, hackers employ strategies like encryption and packing. These evasive maneuvers need Few-Shot models to be sufficiently robust. According to research, detection models' accuracy tends to decline as the number of classes (N) rises. On the other hand, accuracy increases with more shots (K).Some Few-Shot Learning and deep training techniques can be challenging to adjust and need a significant amount of processing power to train. Few-Shot techniques that aren't

made expressly for malware detection can interfere with important features and cause inconsistent results across datasets. Few-Shot models, particularly those with numerous parameters, may nevertheless overfit with very Few-Shots (K), learning the peculiarities of the small sample size instead of effectively generalizing.

EXPERIMENTAL RESULTS

A clear breakdown and interpretation of the visual results are shown in Figure-2 image set. It evaluating a few-shot Prototypical Network with few-shot learning for malware classification, using malware binaries converted to grayscale images. Prototyical Network uses Support Images, which are grayscale visualizations of malware, as a reference set while calculating class prototypes. Horizontal banding and noise, which are characteristic of malware as image files, are visible in the texture. The model compares query images to the support set in an effort to classify them. Data from the same class or family can be identified by their visual similarity to the support set. Figure 2 depicts the Confusion Matrix's single class, Elex. With a modest few-shot experiment, One-Way One-Shot with One-Query Malware images Figure 2 shows that the prediction is 100% accurate. Over 900 episodes, the loss is flat exactly zero. For a small test set, the ROC shows that AUC with 0.75 performs slightly better than random. With a modest few-shot experiment, One-Way One-Shot with One-Query Malware images Figure 2 shows that the prediction is 100% accurate. Over 900 episodes, the loss is flat exactly zero. For a small test set, the ROC shows that AUC with 0.75 performs slightly better than random. Matrix's with two malware image classes, namely Fakerean and Ramn it. It visualizes sample images, training behaviour, classification accuracy, and ROC performance. In Confusion Matrix, the diagonal are mostly bright, indicating strong correct classification, and off-diagonal entries are sparse, showing few misclassifications with accuracy of 99%. Over 1000 episodes, the loss curve drops to zero episodes immediately and stays flat. Loss converges to a low value, indicating successful training and stable learning over time. The ROC curve rises significantly above the diagonal, indicating strong discrimination capability. Legend reports AUC with 0.93, meaning the model can distinguish malware classes with high accuracy. A humble few-shot experiment with Three-Way One-Shot with One-Query analysis, Figure-4 depicts the Confusion Matrix's with three malware image classes, namely Autorun, Obfuscator. Ad and Swizzor. gen!l. It visualizes sample images, training behaviour, classification accuracy, and ROC performance. In Confusion Matrix, the diagonal are mostly bright, indicating strong correct classification, and off-diagonal entries are sparse, showing few misclassifications. Over 1000 episodes, the loss curve drops steeply at first and then gradually declines. Loss converges to a low value, indicating successful training and stable learning over time. The ROC curve rises significantly above the diagonal, indicating strong discrimination capability. Legend reports AUC with 0.86, meaning the model can distinguish malware classes with high accuracy.

A humble few-shot experiment with Three-Way Two-Shot with One-Query analysis, Figure-5 depicts the Confusion Matrix's diagonal are mostly bright, indicating strong correct classification, and off-diagonal entries are sparse, showing few misclassifications. Over 1000 episodes, the loss curve drops steeply at first and then gradually declines. The ROC curve rises significantly above the diagonal, indicating strong discrimination capability. Legend reports AUC with 0.96, meaning the model can distinguish malware classes with high accuracy. A humble few-shot experiment with Five-Way One-Shot with Two-Query analysis, Figure-6 depicts the Confusion Matrix's with five malware image classes, namely Amonetize, Dial platform. B, Fakerean, Neoreklami and Snarasite. It visualizes sample images, training behaviour, classification accuracy, and ROC performance. In Confusion Matrix, the diagonal are mostly bright, indicating strong correct classification, and off-diagonal entries are sparse, showing few misclassifications. Over 1000 episodes, the loss curve drops steeply at first and then gradually declines. Loss converges to a low value, indicating successful training and stable learning over time. The ROC curve rises significantly above the diagonal, indicating strong discrimination capability. Legend reports AUC with 1.0, meaning the model can distinguish malware classes with high accuracy.

A humble few-shot experiment with Five-Way Two-Shot with Two-Query analysis, Figure-7 depicts the Confusion Matrix's with the diagonal are mostly bright, indicating strong correct classification, and off-diagonal entries are sparse, showing few misclassifications. Over 1000 episodes, the loss curve starts high and steadily decreases. The

ROC curve rises significantly above the diagonal, indicating strong discrimination capability. Legend reports AUC with 0.99, meaning the model can distinguish malware classes with high accuracy. A humble few-shot experiment with Five-Way Three-Shot with Two-Query analysis, Figure-8 depicts the Confusion Matrix's with the diagonal are mostly bright, indicating strong correct classification, and off-diagonal entries are zero. Over 1000 episodes, the loss curve drops steeply at first and then gradually declines starts high and steadily decreases. The ROC curve rises significantly above the diagonal, indicating strong discrimination capability. Legend reports AUC with 0.90, meaning the model can distinguish malware classes with high accuracy. A modest few-shot experiment with Five-Way Four-Shot with Two-Query analysis, Figure-9 depicts the Confusion Matrix's with the diagonal are mostly bright, indicating strong correct classification, and off-diagonal entries are sparse, showing few misclassifications. Over 1000 episodes, the loss curve drops steeply at first and then gradually declines starts high and steadily decreases. The ROC curve rises significantly above the diagonal, indicating strong discrimination capability. Legend reports AUC with 0.89, meaning the model can distinguish malware classes with high accuracy.

A modest few-shot experiment with Five-Way Five-Shot with Two-Query analysis, Figure-10 depicts the Confusion Matrix's with the diagonal are mostly bright, indicating strong correct classification, and off-diagonal entries are sparse, showing few misclassifications. Over 1000 episodes, loss decreases sharply early between Episode 0–150 shows model quickly learns basic patterns and **a**round episodes from 350 to 450 episode and from 700 to 850 episodes, the loss spikes back up which suggests something is destabilizing training after initial learning. The ROC curve rises significantly above the diagonal, indicating strong discrimination capability. Legend reports AUC with 0.65, meaning the model can distinguish malware classes with high accuracy. With a few-shot experiment of Seven-Way One-Shot with Two-Query analysis in Figure-11, Confusion Matrix shows the diagonal cell shows 400 correct predictions per class and zero off-diagonal values. This shows perfect classification across all validation query samples. The Prototypical Network has learned extremely separable prototype embeddings. No misclassification across 7 malware families. The loss drops tonear zero extremely quickly within approximately 50 episodes. After that, it remains almost flat at zero all the way to approximately more than 900 episodes. ROC Curve is well above diagonal random baseline and very high true positive rate even at low false positive rates with an AUC of 0.93. Our model shows that Prototypical Network for malware classification is performing extremely well with near-perfect classification, near-zero loss after training, strong discrimination AUC score and separable embeddings across malware families. This strongly supports our model that, Malware binary-to-image conversion effectively captures class signatures, Metric learning is suitable for few-shot malware classification and Prototypes of each class are highly distinct.

With a few-shot experiment of Seven-Way Three-Shot with Two-Query analysis in Figure-12, Confusion Matrix shows each actual malware class is compared against predicted class. Every diagonal position shows correct classifications per class. Almost all off-diagonal cells are zero, which clearly indicates model rarely misclassified, strong class separable and the prototypical network learned effective embeddings. Model accuracy is extremely high and close to 100% on test episodes. Loss starts high and steadily decreases. Eventually loss approaches near zero after approximately 850 episodes. Model converges well, indicating good generalization in few-shot conditions. ROC shows excellent discrimination capability, very low false positives across thresholds and supports that embeddings cluster malware classes effectively with an AUC of 0.92. Prototypical network is working extremely well for malware classification. The embeddings capture distinct malware class signatures, training converges properly, and evaluation metrics show high accuracy and low false positives. With a modest few-shot experiment, Fifteen-Way One-Shot with Two-Query analysis, Figure-13 depicts the Confusion Matrix's with fifteen classes Malware images, namely Autorun, BrowseFox, Dontovo.A, Expiro, FakeRean, Injector3, Kelihos_ver1, Lollipop, Neoreklami, Ramnit, Sality, Stantinko, VBKrypt, Vundo, Wintrim.BX. It is a 2×2 grid of plots summarizing the performance of a Prototypical Network applied to malware classification using image-based malware representations. It visualizes sample images, training behaviour, classification accuracy, and ROC performance. In Confusion Matrix, the diagonal are mostly bright, indicating strong correct classification, and off-diagonal entries are sparse, showing few misclassifications. Over 500 episodes, the loss curve drops steeply at first and then gradually declines. Loss converges to a low value, indicating successful training and stable learning over time. The ROC curve rises significantly above

the diagonal, indicating strong discrimination capability. Legend reports AUC with 0.86, meaning the model can distinguish malware classes with high accuracy. Totally, this shows that a Prototypical Network trained on grayscale malware images achieves steadily decreasing loss, accurate multi-class classification as seen in the confusion matrix and strong ROC performance.

With a modest few-shot experiment, Fifteen-Way Two-Shot with Two-Query analysis, Figure-14 shows that the diagonal of the Confusion Matrix is the brightest with higher counts showing strong correct prediction. Over 500 episodes, the loss decreases sharply early on, then tapers and flattens, showing training convergence. The orange ROC curve rises steeply toward the upper-left corner, indicating strong performance. The legend reports **AUC = 0.94**, which With a modest few-shot experiment, Fifteen-Way Three-Shot with Two-Query analysis, Figure-15 shows that the diagonal of the Confusion Matrix is the brightest with higher counts showing strong correct prediction. Over 500 episodes, the loss decreases sharply early on, then tapers and flattens, showing training convergence. The orange ROC curve rises steeply toward the upper-left corner, indicating strong performance. The legend reports **AUC = 0.97**, which is a high classification quality score. is a high classification quality score. Figure-16 shows a bar chart comparing AUC (Area under the ROC Curve) scores for different N-Way K-Shot configurations. The model performs extremely well overall. 5-Way 1-Shot being highest may indicate good feature generalization. Increasing more samples per class improves AUC. Increasing more classes generally makes the task harder.Figure-17 shows a f1-score performance remains very high overall and all scores are above 0.90. One-Way One-Shot & Seven-Way One-Shot **show** perfect score of f1 = 1.00. Slight dip as the task becomes more challenging. Fifteen-Way Three-Shot still maintains strong performance score of 0.92, despite many classes. As the number of classes (N) increases, the F1-score shows a small decline due to increased classification complexity. Increasing the number of support samples (K-Shot) helps mitigate performance drop. Overall, the model demonstrates strong generalization across a wide range of few-shot configurations.

CONCLUSION

Our postulated CNN architectures can be utilized to address issues unique to malware, such as the lack of samples for particular families and the requirement to categorize unknown families due to zero-day threats and malware family evolution. We demonstrate empirically that our Few-Shot categorization is stronger. Our few-shot classification can be used to categorize unknown malware families and is still consistent with the conventional malware classification. In an effort to improve performance in subsequent work, we give insights for some of the classifications our classifier models make. Finally, we present the performance improvement we attained by comparing our work with the state of the art. We showed experimentally that the Few-Shot Learning with Prototype Network architecture outperformed the state-of-the-art other malware classification study and achieved competitive results for the traditional classification. In order to enable faster training and classification, this study suggested a Few-Shot Learning with Prototype network that works better with shallower CNN architectures than the conventional deeper architectures. As a result, the classifier would be more resilient to complex obfuscation methods. Also, this visualization in figures shows that a Prototypical Network trained on malware images achieves low training loss, high classification accuracy across multiple malware families, and a strong ROC performance. Our method can be used for dynamic malware analysis in future research.

ABSTRACT

The emergence of social networking sites has not only dramatically transformed the way information is exchanged and users interact with each other but has also significantly used to boost endogenous negative effects including misinformation, rumors, cyber bullying, propaganda, spamming, toxicity, and coordinated manipulations. These factors create a serious danger to the credibility of information, confidence of users, stability and resilience of communities, and of the digital ecosystem as a whole. This survey reviews some of the most recent advances in addressing the problem of endogenous negative influences via node-based intervention techniques. In total, 22 analysis published between 2024 and 2026 are considered and classified into three categories including negative influence modeling, node-centric interventions, and intelligent graph learning and optimization. Graph theory, influence diffusion models, machine learning, deep learning, graph neural networks, graph transformers, reinforcement learning, and optimization techniques related to the detection of key nodes and negative influence control are reviewed in detail. Comparative analysis allows specifying current approaches, datasets used, advantages, disadvantages, as well as the existing analysis gaps. The combination of graph intelligence, adaptive artificial intelligence, and node-based interventions can be considered as a promising method of developing reliable, resilient, and trustworthy social networking platforms.

Keywords: Critical Node Identification, Endogenous Negative Influence, Graph Neural Networks, Influence Propagation, Node Intervention, Social Network Analysis

INTRODUCTION

The advent of social networks as powerful tools to facilitate communications, information sharing, and opinion generation has paved the way for the fast transmission of good and bad information among connected users. Negative influences like misinformation, rumor, cyber bullying, propaganda, coordination attacks, spam, and emotional polarization spread via the natural interaction process of users, causing serious risks to the validity of information, social trustworthiness, social stability, and the resilience of the whole social network system. Most analysis efforts have been devoted to the problem of detecting harmful influences after the dissemination process of harmful content rather than actively blocking the spread of such harmful influences. Current efforts suffer from the limitation of the lack of integrated node-based intervention, intelligent graph adaptation, influence prediction based on temporal modeling, real-time optimization, and community-based influence blocking. The coordination analysis of information operations used to identify patterns of behavior interactions and synchronized user activities, which made it possible to detect organized influence campaigns on Twitter social network platforms and gain a better understanding of the manipulation strategies used [1].

The Temporal Tree Transformer used to improve the efficiency of rumor detection due to its ability to model the structure and characteristics of rumor propagation in social networks [2]. Machine learning algorithms improved the performance of fake news detection by performing feature engineering, semantic representation, and classification of misinformation content [3]. The comparative analysis evaluated the efficiency of convolutional neural networks, large language models, and natural language processing approaches, proving efficiency for detecting fake news [4]. The hybrid Light-ANFIS approach performed feature clustering, gradient sampling, and adaptive neuro-fuzzy inference for efficient spam detection [5]. The fine-tuning of deep learning algorithms enhanced the detection of propaganda by virtue the ability to analyze the contextual language of the content and diffusion properties to detect the presence of manipulative content within public social media forums [6]. The use of chained deep learning techniques for the identification of cyber bullying activities considered bystander behavior patterns and interdependencies in order to accurately identify cyber bullying activities [7]. Sentiment analysis coupled with machine learning algorithms was used to improve cyber bullying detection by using contextual emotions and linguistic analysis from social media communication [8]. Cyber bullying activities were effectively detected by the use of deep learning algorithms by analyzing the textual content of social media communications [9]. Hybrid deep neural network models aided in opinion mining by using semantic analysis and contextual dependencies [10]

Background Study

P. Anthony and J. Zhou (2025) [11] presented a Transformer with self-attention for multi-label emotion classification of crisis tweets. While the algorithm enhanced contextual emotion recognition, it did not have influence propagation modeling and any intervention strategy, thereby having limited application to endogenous influence suppression. The model accurately classified emotions in a multi-label setting. X. Zhao et al. (2024) [12] presented a multi-attribute decision making technique for identifying critical nodes in complex networks. Even though the method incorporated multiple attributes for influential node ranking, the temporal aspect of influence propagation and adaptive intervention were missing in it, which made its dynamic suppression capability unclear. N. Bendahman and D. Lotfi (2024) [13] developed a new centrality measure in graph theory for influence. Although the method was effective for finding influential nodes, the missing features included graph learning, optimization and intervention. P. Xu et al. (2025) [14] presented a Graph neural networks with evolutionary optimization for proactive rumor control. The approach enabled the suppression of rumors with intelligent optimization, but the primary focus was on rumors spread. H. Wang et al. (2024) [15] introduced the HEDV-Greedy technique in the area of hypergraph influence maximization. The algorithm was superior to the other algorithms in terms of accuracy of the solution, but it was focused on influence maximization and not on adaptive node intervention for suppressing endogenous negative influence. The table 2 presents the comparison of recent graph learning and optimization techniques in the context of intervention in the social network. While achieving excellent accuracy in terms of classification through the use of

graph neural networks and transformer-based models, most of the analysis focused on the classification of harmful content.

Research Gap

The existing literature in this area has mainly been geared towards detection and classification of harmful information such as misinformation, rumors, cyberbullying, fake news, spam, misinformation, among others through the use of graph learning, machine learning, and deep learning methods. Despite making tremendous gains in terms of accuracy and classification of such information, the major problem is that these methods work after the spread of harmful information. Therefore, there is need to analysis how to adaptively control influence through intervention of nodes, influence suppression in real-time, preventing cascades, optimizing critical nodes, and mitigating endogenous negative influence, among others.

Modeling of Endogenous Negative Influence in Social Networks

Endogenous negative influence is carried out owing to constant interaction between connected users, which allows the quick spread of disinformation, rumors, cyber bullying, propaganda, spam, and emotional polarization in the social network. It is important to consider the processes of diffusion, interactions among users, patterns of propagation, and the topology of the network to build an intelligent system that would suppress the influence without disturbing the exchange of valuable information. Coordinated information operations were designed to analyze the synchronized behavior, interaction, and collaboration of the users in order to find out the malicious influence operations in the networks of Twitter [1]. The analysis made significant progress in analyzing the manipulation operations and coordinated behavior; however, there were no methods for node intervention and adaptive influence suppression. Temporal Tree Transformer analyzed the process of rumor propagation by extracting the process structure and its features, achieving 75.84% accuracy and 71.98% Macro-F1 [2]. This approach used to improve detection and representation of temporal features but did not pay much attention to the detection itself.

False information was detected by machine learning approaches using language, semantics, and context information extracted from online data [3]. The BERT approach attained high accuracy and ROC-AUC, ensuring excellent classification capacity for misinformation. Nonetheless, adaptive approaches that control influence propagation and restrict misinformation spread have not been invented yet. Comparative analysis on the effectiveness of Convolutional Neural Networks, Large Language Models, and Natural Language Processing approaches was conducted to classify the news as fake [4]. The fine-tuned GPT-4 Omni framework reached high accuracy and performed much better in comparison with classical CNN algorithms. Nevertheless, there is no analysis about influence propagation modeling and intervention. Light-ANFIS approach based on adaptive neuro-fuzzy inference system, feature clustering, and gradient-based sampling was used to detect spam with the high precision in social networks [5]. Light-ANFIS approach provided high accuracy and F1-score, which ensured high-classification capability. However, there is no discussion about influence propagation, modeling, and node-based intervention. Fine-tuned RoBERT a framework provided propaganda identification through diffusion-aware learning and contextually aware language understanding with 88% accuracy, showing superior results than LSTM-based approaches [6]. Although propaganda detection is highly improved, adaptive influence propagation control and intervention have not been developed.

Chained deep learning approach incorporated bystander roles and the dependency for the detection of cyber bullying [7]. The model developed had better classification performance of 25.35% with an F1-score of 89%. However, intervention techniques that could be used to prevent the spread of cyber bullying were not mentioned. Sentiment analysis and machine learning were integrated for improving the performance of cyber bullying detection by analyzing the emotional context and linguistic attributes of interactions in social media [8]. With the use of the Extra tree classifier, the performance of detection of cyber bullying was 95.38% and the F1 score 0.95. However, influence propagation in the network and adaptive interventions were not considered.

Deep learning models used for detecting cyber bullying on the Twitter, Instagram, and Facebook dataset resulted in significant improvement of accuracy with the results of 96.64%, 94.49%, and 91.26%, respectively [9]. Although accuracy was improved, adaptive node selection and cascade prevention were not considered. The Hybrid BGRU-LSTM model used to improving the performance of opinion mining through learning semantic and contextual dependencies of social media discussions [10]. It resulted in an accuracy of 95%, negative recall 96% and reduction of misclassification. However, influence propagation and dynamic opinions were not considered. Transformer self-attention detected multiple label emotions from crisis-related tweets with micro-F1 score of 0.7208, macro-F1 score of 0.6192, and 3% better than baseline models [11]. Even though there is progress in performance of emotion detection systems, there is still insufficient analysis related to emotional influence spreading, cascade, and proactive intervention.

Node-Based Interventions for Influence Mitigation

Node-based intervention approach for mitigation of the influence effect of endogenous negative influence involves selection of influential nodes, vulnerable nodes, or strategic nodes and then use intervention techniques for disrupting the spreading of the negative influence. By combining the graph structure, centrality, influence propagation, and optimization, such strategies manage to mitigate cascades of negative influence without compromising legitimate communication and integrity of the network connectivity. By applying multi-attribute decision-making approach, important nodes are selected based on several attributes of network structure including centrality [12]. Such approach improved accuracy in selecting and identifying critical nodes but did not provide an adaptive intervention strategy. Influence detection has been made possible using novel graph-based centrality measures with network topology analysis and graph models techniques, thereby improving the influence measurements on complex networks [13]. While node ranking had been enhanced, graph learning and optimization as well as node intervention methods had not been used for controlling the endogenous negative influences.

Graph neural networks with evolutionary optimization method had been utilized for proactive control of rumors by locating the influential nodes that would minimize the information dissemination [14]. The method allowed the improvement of rumor control via node optimization, although it remained within the sphere of rumor spreading and ignored the issue of endogenous negative influence in general. HEDV-Greedy algorithm had enabled maximizing influence propagation on hypergraphs through locating the influential nodes with the improvement of average solution accuracy of 25.76% in comparison with other algorithms in the cases of low propagation probabilities [15]. Despite the success of the algorithm in terms of optimization, it focused on influence maximization and not suppression and cascade prevention The figure 1 provides a comparison of effectiveness of node intervention techniques based on six major criteria for evaluating the performance of such approaches as critical node identification, cascade blocking, community preservation, cost of intervention, influence reduction, and scalability. It can be seen from Figure 1 that sophisticated techniques provide a high level of influence reduction and community preservation with scalability at the same time.

Intelligent Graph Learning and Optimization for Social Network Intervention

Intelligent graph learning is a technique that applies graph neural networks, graph transformers, deep learning, and optimization for modeling complicated influence propagation process, identification of critical network nodes, and adaptive intervention strategy development. The intelligent computing methods will make the intervention strategies scalable, robust, and effective in suppressing endogenous negative influences. Graph convolution networks combined with deep feature extraction were used to detect social media trolls through efficient learning of structural and interaction relationships of users in social networks [16]. However, the approach considered only accuracy in detection without adaptive node intervention and influence suppression methods. The Graph-Augmented Transformer Ensemble (GETE) approach improved fake news detection by combining graph structures with transformer-based contextual learning methods to achieve 96.5% accuracy, 96.5% F1-score, and high ROC-AUC [17]. However, the method failed to address the problem of proactive node intervention and adaptive influence suppression.

A contrastive hybrid graph neural network leveraged interaction signals of users and content representation for the detection of fake news and hate speeches, reaching high accuracy, 96.72% precision, 96.15% recall, and 96.43% F1-score [18]. Nonetheless, this framework considered content classification but did not take into account adaptive intervention for influence mitigation. Graph neural networks that used deep learning methods enhanced the detection of fake news through graph relationships and semantic representation, reaching high classification accuracy in benchmark datasets [19]. While demonstrating excellent detection performance, this framework lacked identification of critical nodes and graph-based influence suppression mechanism. Emotion-RGC Net was designed by combining RoBERTa and graph neural networks for the purpose of capturing semantic and relational data for emotion detection, obtaining 89.70% accuracy on Sentiment140 and 88.50% accuracy on Emotion dataset [20]. This model focused on the task of emotion classification but did not address influence intervention or suppression. A hybrid multi-view ensemble framework divided heterogeneous data and leveraged intelligent ensemble learning for the detection of fake news and obtaining an outstanding high accuracy with robustness to data perturbation [21]. Nonetheless, this framework did not consider adaptive node optimization and influence suppression.

The hybrid deep learning approach used Fast Text, Explainable AI, and transformers for optimizing the identification of fake news, obtaining a very high accuracy and F1-score on various data sets [22]. Even though the model offered excellent accuracy and interpretability, the adaptation of graph-based intervention and suppression of negative influence were not addressed. The figure 2 shows the performance of high-level artificial intelligence models and graph learning models is compared in for the purpose of social network analysis and intervention. The hybrid approach using Fast Text and explainable AI with transformer optimization gave the best performance, followed by graph neural network-based models. This comparison shows that the combination of graph intelligence, deep learning, and ensemble approach greatly improves performance. The table 2 present a recent deep learning methods applied to social network analysis have been compared, where Transformer, graph neural network, and hybrid architectures consistently yielded better results, which made it possible to accurately detect misinformation, rumors, cyber bullying, and influence propagation patterns.

CONCLUSION

In this survey, the recent literature related to the suppression of endogenous negative influence in social networks via the node-level intervention approach has been comprehensively reviewed. The analysis showed considerable progress in modeling influence propagation, critical nodes identification, and the prevention of such negative phenomena as misinformation, rumors spreading, cyberbullying, spamming, propaganda, fake news, and polarization, which were carried out using machine learning, deep learning, graph neural networks, graph transformers, and optimization approaches. Nonetheless, the current methods still pose certain limitations with regard to the problems associated with influence evolution, scalable and real-time intervention, adaptive node selection, computation complexity, heterogeneous network structure, and maintaining community connectivity in suppressing influences. The review stresses the importance of intelligent and pro-active intervention approaches that will use to prevent any kind of negative influence from taking place before a large-scale cascade occurs. Further analysis should be devoted to the development of such approaches as the integration of graph foundation models, graph transformer, reinforcement learning, explainable artificial intelligence, digital twin social network, and privacy-preserving federated learning. Moreover, the creation of autonomous node-based suppression approach to influences will be beneficial for establishing safer and trustworthy social network ecosystems.

ABSTRACT

Environmental sustainability has become a global priority and so it is essential to enhance the environmental communication. In this connection, the present study examined the role of faith-based communication in promoting environmental sustainability among selected Church of South India (CSI), Roman Catholic (RC), and Pentecostal churches in Madurai. The study adopted a descriptive and comparative research design, employing both quantitative and qualitative methods. Primary data were collected from 300 church members through a structured questionnaire, supplemented by interviews with pastors, priests, and church leaders, as well as focus group discussions. Secondary data were gathered from books, research journals, church publications, environmental reports, official church websites, and government publications. The findings indicated that environmental sustainability was communicated through sermons across all three denominations, with Roman Catholic churches demonstrating comparatively higher levels of communication, followed by CSI and Pentecostal churches. Sermons addressing environmental stewardship, pollution control, creation care, and global sustainability were found to enhance environmental awareness and encourage environmentally responsible attitudes among church members. The study is concluded that faith-based communication, particularly sermon communication, serves as an effective platform for promoting environmental sustainability and recommends greater integration of environmental themes into church ministries and community outreach programmes.

Keywords: Faith-Based Communication –Christian denominations – Environmental issues - Environmental Stewardship- Environmental Sustainability

INTRODUCTION

Environmental sustainability has emerged as one of the most pressing global challenges of the twenty-first century due to depletion of natural resources, pollution, biodiversity loss, and the climate change. Although governments, environmental agencies, and non-governmental organizations have taken significant steps to address these concerns, religious institutions also possess considerable potential to influence public attitudes and behaviours toward environmental stewardship. Across the world, faith communities communicate moral values and ethical responsibilities through structured patterns of religious communication that are deeply rooted in their traditions. In Christianity, communication forms the foundation of worship and spiritual formation, occurring through music, prayers, sermons, liturgy, pastoral counselling, and digital media. These communication practices shape the beliefs, values, and daily lives of believers. Christian teachings affirm that the earth is God's creation and that humanity has been entrusted with the responsibility of caring for it. By integrating biblical principles of stewardship, justice, compassion, and care for creation into faith-based communication, churches have the potential to encourage environmentally responsible attitudes and sustainable lifestyles among their congregations. Understanding how churches communicate environmental values is therefore essential for exploring the contribution of religion to contemporary sustainability efforts.

Among the various forms of communication employed in Christian worship, the sermon occupies a central position as the primary means of conveying biblical teachings, shaping moral values, and inspiring behavioural change. Through sermon communication, clergy interpret Scripture, address contemporary social concerns, and encourage believers to apply Christian principles in their personal and communal lives. Sermons therefore provide an effective platform for promoting environmental stewardship as an expression of Christian faith and discipleship. Despite the growing global discourse on religion and sustainability, limited research has comparatively examined how different Christian denominations communicate environmental responsibility through sermons. This study addresses this gap by investigating sermon communication in selected church denominations in Madurai. The significance of the study lies in its potential to demonstrate how faith-based communication can contribute to environmental sustainability by fostering ecological awareness, ethical responsibility, and community engagement. On these perspectives, the objectives of the research were framed and they have been materialized by adopting methodologies. The research outcomes have been documented in the present paper.

LITERATURE REVIEW

Faith-based communication has increasingly been recognised as a significant avenue for promoting environmental sustainability by integrating ecological concerns with religious values and moral teachings. Although research findings are mixed regarding the overall impact of religion on environmental protection, scholars consistently argue that communication grounded in religious values, particularly stewardship, creation care, and moral responsibility, is more effective than generic environmental messaging. Haluza-Delay (2017) emphasized that environmental communication within religious communities should employ narratives, symbols, and theological language that resonate with the beliefs and traditions of the faith community. Such an approach enhanced the credibility and acceptance of environmental messages among believers. Experimental studies further support the effectiveness of faith-based environmental communication. Goldberg et al. (2019) demonstrated that stewardship-framed messages significantly increased pro-environmental attitudes and climate change concern among Christian participants by presenting environmental protection as a moral and religious obligation. Similarly, Shin and Preston (2019) found that participants who were exposed to biblical passages emphasizing stewardship expressed stronger concern for climate change than those who read passages emphasizing human dominion over nature. Complementing these findings, DePalma (2022) reported that religious Americans were more persuaded by deontological (duty-based) ethical appeals than by utilitarian arguments when considering climate mitigation, highlighting the importance of moral responsibility in faith-based environmental communication.

Despite these encouraging findings, evidence regarding long-term behavioural change remains limited. Studies suggested that while faith-based communication effectively enhanced environmental awareness and positive attitudes, its influence on sustained environmental behaviour varied across contexts. Research conducted among Lutheran congregations found that although fewer than half of the participants adopted new conservation practices, many developed a stronger sense of place and a greater commitment to caring for creation. Brown et al. (2021) further observed that the influence of sermon-based environmental messages differed across racial groups, with stronger associations between sermon exposure and support for environmental policies among White congregants than among Black and Hispanic congregants. These findings indicated that the effectiveness of environmental communication depended on cultural context, audience characteristics, and the credibility of the messenger. Although substantial research has examined religion and environmental communication, comparatively little attention has been given to the role of sermon communication across different Christian denominations in the Indian context. Existing studies primarily focus on Western congregations and often examine environmental attitudes rather than the communication processes within worship. Therefore, there remains a significant research gap in understanding how sermons communicate environmental sustainability in diverse denominational settings such as the Church of South India (CSI), Roman Catholic, and Pentecostal churches. The present study seeks to address this gap by comparatively analysing sermon communication on environmental sustainability in selected church denominations in Madurai.

Research Objectives

- Examine the environmental themes communicated through sermons in the selected church denominations,
- Compare the approaches adopted by selected church denominations in communicating environmental stewardship.
- Evaluate the potential of sermon communication to promote environmental awareness and sustainable practices among Christian congregations.

RESEARCH METHODOLOGY

Research Design

This study adopts a descriptive and comparative research design to examine the role of faith-based communication in promoting environmental sustainability among selected Christian church denominations in Madurai. The descriptive approach is employed to understand the existing patterns of environmental communication, environmental awareness, and communication practices within churches. The comparative approach enables the researcher to identify similarities and differences in faith-based environmental communication among the Church of South India (CSI), Roman Catholic (RC), and Pentecostal churches. This research design is appropriate as it facilitates a systematic comparison of communication practices and their influence on environmental sustainability across different denominational contexts.

Study Area

The study is conducted in Madurai District, Tamil Nadu, where three major Christian denominations the Church of South India (CSI), Roman Catholic (RC), and Pentecostal churches have a significant presence. Selected churches from each denomination constitute the study area. Madurai provides an appropriate setting due to its religious diversity and the active participation of churches in spiritual, social, and community development activities.

Sample

The study comprises a total sample of 150 respondents, distributed equally among the three selected Christian denominations to facilitate meaningful comparative analysis. In addition to the survey respondents, pastors, priests, and church leaders from the selected churches will participate in interviews to provide qualitative insights into faith-based communication and environmental sustainability.

Sampling Technique

The study employs a combination of simple random sampling and purposive sampling. Simple random sampling is used to select church members for the questionnaire survey, ensuring that every eligible member has an equal opportunity to participate. Purposive sampling is adopted to select pastors, priests, and church leaders who possess extensive knowledge and experience regarding church communication, sermon preparation, and environmental initiatives. The integration of these sampling techniques ensures both representative quantitative data and in-depth qualitative perspectives.

Data Collection

The study relies primarily on primary data collected from church members and religious leaders.

Primary Data

Primary data is collected using the following methods:

- Structured Questionnaire: A structured questionnaire is administered to 300 church members to gather information on environmental awareness, attitudes toward environmental sustainability, exposure to faith-based communication, and perceptions of sermon messages related to environmental stewardship.
- Interviews: Semi-Structured interviews is conducted with pastors, priests, and church leaders to understand how environmental sustainability is incorporated into sermons, church teachings, and other communication activities.
- Focus Group Discussions (FGDs): Focus group discussions with selected church members will provide deeper insights into their understanding of environmental stewardship, the influence of faith-based communication on their environmental attitudes, and suggestions for strengthening environmental communication within churches.

Secondary Data

Secondary data is collected from various published sources to support the study and provide theoretical and contextual information on faith-based communication and environmental sustainability. The sources include:

- Books on communication, environmental sustainability, theology, and religion.
- Research journals related to communication, environmental studies, and religious studies.
- Church publications, including pastoral letters, newsletters, and official documents.
- Environmental reports published by national and international organizations.
- Church websites providing information on environmental initiatives and church activities.
- Government publications related to environmental policies, sustainability, and conservation.

Data Analysis

The data collected through the structured questionnaire is coded, tabulated, and analyzed. Descriptive statistical techniques, including frequency, percentage, mean, and standard deviation, are used to summarize the demographic characteristics of the respondents and their perceptions of faith-based communication and environmental sustainability. Comparative analysis is conducted to examine differences among the Church of South India (CSI), Roman Catholic (RC), and Pentecostal churches. Qualitative data collected through interviews and focus group discussions will be analyzed using thematic analysis, where responses are organized into key themes and interpreted to support and enrich the quantitative findings.

RESULTS AND DISCUSSION

The present study not only focuses on the analysis of the content of the sermons, but also focuses on the comparative analysis of sermon delivered in different denominations. In this connection, the standard methodology was adopted and the results have been presented in the tables. Table presents the percentage of science communication in sermons and percentage of environmental communication in science communication of the sermons delivered across the

selected church denominations. The findings reveal that the Church of South India (CSI) had the highest level of science communication in sermons (28%), followed by the Roman Catholic Church (21%) and Pentecostal churches (16%). A similar trend was observed for environmental communication within science-related sermons, where CSI churches recorded the highest percentage (22.3%), followed by Roman Catholic churches (17.2%) and Pentecostal churches (12%).The table indicate that although all three denominations incorporate science related topics into their sermons, the overall level of science communication remains relatively low as expected. Among the science-related contents, environmental issues constitute a substantial proportion, particularly in CSI churches.

The table indicate that the selected church denominations emphasize different aspects of environmental protection in their sermon communication. The Church of South India (CSI) places the greatest emphasis on water protection (62.5%), followed by air protection (22.3%) and land protection (15.2%), highlighting the importance of conserving water resources. Similarly, Pentecostal churches also prioritize water protection (63%), with comparatively lower emphasis on land protection (24.5%) and air protection (12.5%). In contrast, the Roman Catholic Church gives the highest priority to air protection (65%), while land protection (19.5%) and water protection (15.5%) receive less attention. Overall, the findings suggest that although all three denominations incorporate environmental protection into their sermons, the areas of emphasis differ in terms of environmental sustainability.

The table indicate that the selected church denominations communicate both global environmental issues and global sustainability through their sermons, although the emphasis varies across denominations. The Church of South India (CSI) places greater emphasis on global sustainability (56.3%) than on global environmental issues (42.7%), suggesting a stronger focus on promoting sustainable practices and environmental stewardship. Similarly, Pentecostal churches record the highest emphasis on global sustainability (64.9%), while 35.1% of their sermon communication addresses global environmental issues. In contrast, the Roman Catholic Church places slightly greater emphasis on global environmental issues (51.5%) than on global sustainability (44.5%), reflecting a balanced approach to discussing global ecological challenges alongside sustainable development. Overall, the findings suggest that while all three denominations recognize the importance of environmental concerns, they differ in their communication priorities, with CSI and Pentecostal churches focusing more on sustainability and Roman Catholic churches giving relatively greater attention to global environmental issues.

CONCLUSION

The study concludes that faith-based communication plays a significant role in promoting environmental sustainability among Christian congregations. The findings reveal that sermons across the Church of South India (CSI), Roman Catholic, and Pentecostal churches incorporate environmental themes such as creation care, stewardship, pollution control, and sustainable living, although the extent of coverage varies among denominations. Roman Catholic churches demonstrated the highest level of environmental communication, followed by CSI churches, while Pentecostal churches showed comparatively lower emphasis on environmental issues. Overall, the study highlights that sermon communication serves as an effective platform for creating environmental awareness, strengthening biblical understanding of stewardship, and encouraging environmentally responsible attitudes and practices among church members. The findings further emphasize that integrating environmental sustainability into faith-based communication can contribute to achieving broader social and ecological well-being.

Suggestions

Based on the findings of the study, it is recommended that churches shall integrate environmental sustainability more consistently into sermons, study sessions, worship programmes, and other faith-based communication activities. Church leaders shall receive orientation and training on environmental stewardship so that biblical teachings can be effectively linked with contemporary environmental challenges. Churches may organize awareness campaigns, tree-planting programmes, waste management initiatives, and water conservation activities to encourage practical environmental action among congregations. Greater collaboration between churches, educational

institutions, environmental organizations, and government agencies can further strengthen community participation in sustainability initiatives. Finally, future research may expand the scope of this study by including other religious communities, larger geographical areas, and additional forms of faith-based communication such as church music, digital media, and social outreach programmes.

ABSTRACT

Paternal perinatal mental health is an emerging public health concern that remains under-recognized in India and globally. Depression and anxiety among expectant fathers can adversely affect maternal well-being, couple relationships, father–infant bonding, and child development. This review explores the major psychosocial factors associated with paternal perinatal depression and anxiety and highlights evidence-based interventions relevant to the Indian context. A descriptive review methodology was adopted to synthesize literature from Indian and international sources on paternal perinatal mental health. Relevant studies were reviewed to identify key themes related to depression, anxiety, work–family conflict, financial stress, social support, relationship stress, psychoeducation, and self-care among expectant fathers. The review also incorporated multidisciplinary perspectives from psychiatry, psychology, psychiatric social work, obstetrics, nursing, and public health. The review revealed that paternal depression affects approximately 10% of fathers globally, while Indian hospital-based studies report a higher prevalence of 20–25%. Anxiety among expectant fathers was associated with financial difficulties, fear of childbirth complications, role transition concerns, irritability, insomnia, and poor spousal communication. Work–family conflict, long working hours, job instability, and financial stress emerged as significant contributors to psychological distress. Strong social support networks, peer-group interventions, couple-based counseling, psychoeducation, and self-care practices were identified as protective factors that enhance paternal resilience and improve father–infant bonding. Paternal perinatal mental health should be recognized as an essential component of family-centered healthcare in India. The findings underscore the need for culturally sensitive, multidisciplinary interventions integrating

psychiatrists, psychologists, social workers, obstetricians, nurses, and public health professionals. Incorporating paternal mental health screening, psychoeducation, peer support, and counseling into routine antenatal and postnatal care may improve the psychological well-being of fathers, strengthen family relationships, and promote healthier developmental outcomes for children.

Keywords: Paternal, Perinatal, Psychosocial factors, Depression, Anxiety, Descriptive Review

INTRODUCTION

Perinatal mental health of fathers has come to be recognized as a vital but under-researched area of concern at the international and Indian levels. Evidence from an international meta-analysis of 48 cohorts, done in 2025, suggests that depression, anxiety, and stress in expectant fathers during the perinatal period can lead to worse developmental outcomes in children up to adolescence in terms of social-emotional, cognitive, and linguistic development (Le Bas*et al*. 2025). In the Indian scenario, studies done in Delhi and Bengaluru tertiary hospitals found that close to 20-25% of expectant fathers have symptoms of depression, mainly due to reasons like economic pressure, conflict between work and family life, and lack of social support. These results point towards the absolute necessity for culturally-appropriate intervention efforts. Diagnoses of paternal depression and anxiety are the responsibility of Psychiatrists, while Clinical Psychologists offer evidence-based treatments in the form of Cognitive Behavioral Therapy (CBT), which has yielded successful results internationally. Psychiatric Social Workers play their part in making community-level networks of support and overcoming stigmatization and resource barriers. Community-level interventions carried out in Kerala have shown that peer-group support for fathers improves father-infant bonding.
In this regard, Obstetricians play a major role in ensuring that the psychological welfare of fathers is included in their routine antenatal clinics since they should not be excluded from care programs that are centered on mothers (Kothari, Dulhunty& Callaway, 2024). Mental Health Nurses play a vital role in the provision of counseling and observation services in hospitals through visiting patients. Public Health Specialists are more concerned about strategies that involve the entire population. In 2026, a systematic review of interventions performed in 11 different countries revealed the significance of psychoeducation and peer support.

METHOD

Descriptive review was used as the basic research approach in the current study with certain distinct advantages that existed in the case of paternal perinatal mental health (Kumara, 2022). The current research entailed a systematic review of the literature from both Indian and international sources and this helped the researchers get different perspectives on the topics of anxiety, depression, financial problems, change in relationship, sleep problems, lack of social support, conflict at workplace, etc., among expectant fathers. descriptive review research was helpful in ensuring efficiency of the process because of the ready availability of information and absence of necessity for a lot of efforts in collecting the information from various sources (Areco*et al*., 2021). Along with this, it also made it possible for the researchers to identify the gaps in knowledge about the subject matter. Along with this, descriptive review research allowed the researchers to adopt a multidisciplinary approach through inputs from Psychiatrists, Clinical Psychologists, Psychiatric Social Workers, Obstetricians, Mental Health Nurses, and Public Health Professionals.

RESULTS

Prevalence of Paternal Depression

The Descriptive review highlights the importance of the issue of paternal depression during the perinatal period which remains largely unexplored. As per a meta-analysis of 48 cohorts in different parts of the world, about 10

percent of fathers go through clinical depression either during the time of pregnancy or after the birth of their baby. The prevalence rate is quite high at around 20-25 percent in case of Indian studies conducted in Delhi and Bengaluru hospitals (Ramani & Suresh,, 2020). These statistics are way more than the overall worldwide prevalence rate, and it shows that there must be certain cultural aspects that make the fathers more vulnerable in India. Paternal depression adversely affects the development of children and results in language development and socio-emotional issues (Dachew*et al.,* 2023). With the help of Descriptive review methodology, this research was able to collect information from varied sources and thus proved that paternal depression should not only be looked at as a clinical issue but as a public health issue.

Impact of Anxiety on Family Dynamics

The Descriptive review literature reveals that paternal anxiety during the perinatal period influences family relations and relation between husband and wife. The literature from abroad shows that 15% of expectant fathers suffer from anxiety due to certain reasons including financial difficulties, fear of problems with delivery and problems with role assumption. The literature from India shows that the descriptive review literature carried out in hospitals also confirms these data as anxiety manifests itself through irritability, insomnia and poor communication between spouses. Paternal anxiety can influence the psychological state of women as anxious fathers do not provide psychological support to their wives, and it leads to their depression (Basili*et al.,* 2021). Moreover, it was found in the literature that fathers' anxiety has an impact on the bonding between fathers and babies. Therefore, it can be concluded that anxiety is a circular problem as the anxiety of the father increases the anxiety of women and affects the life of children. CBT and psycho education are effective methods worldwide and may work in Indian cultural environment (Raman, 2020).

Work-Family Conflict and Economic Stress

The issue of work-family conflict comes up as one of the key themes emerging from the literature review on paternal perinatal mental health. Research done in India brings out the economic stressors such as increased cost of health care, instability of job and responsibilities to the extended family as some of the stressors of fathers (Sahoo, Rout& Jakovljevic, 2023).As per the findings of the systematic review study done in the year 2026 in 11 countries, fathers working for long hours and having unstable jobs were found to be vulnerable to depression and conflicts with their partners. In India, fathers face problems in balancing between their occupational responsibilities and being caregivers; hence, the feeling of guilt and relationship conflicts with their spouses. Work-family conflict has also been identified as one of the reasons why fathers are at risk of substance abuse and estrangement from the family members (Tanquerel& Grau-Grau, 2020). All these points have been captured in the descriptive review in order to underscore the need for proper work policy for fathers.

Role of Social Support Networks

The Descriptive review research has always indicated social support systems as protective factors for paternal mental health. The research done across the globe indicated that male individuals having good peer and family support had lower chances of getting affected by depression and anxiety. In India, the community-level intervention implemented in the state of Kerala has proved that the peer group support helped improve father-baby bonding and reduced the stigma around paternal mental health (Parasuraman et al., 2024). The research further reveals that fathers might find themselves isolated within the mother-centric healthcare delivery system.Thus, after considering all the findings, descriptive review indicates that paternal involvement in antenatal and post-natal programs is necessary. From the experiences of interventions implemented at the population level in various countries like Australia and Canada, it can be seen that systematic peer support and family counseling help build up paternal resilience. In the Indian setting, culturally sensitive peer groups like Father Support Circles in communities can do the same job (Yadav*et al.,* 2022).

Couple Relationship Stress

Based on the secondary sources, the increase of stress associated with partners happens during the perinatal period due to the role transitions, financial stress, and exhaustion. At the international level, research showed that stress

problems of fathers lead to marital conflicts, low intimacy, and communication problems. Taking into account the situation in India, according to the hospital research, those fathers of pregnant women who had high levels of stress had problems with their partners, which negatively affected maternal health (Suryawanshi, Rajaseharan& Venugopal, 2021). Also, based on the descriptive review sources, stress in the relationships reduces cooperative parenting that influences child development. The consolidation of results obtained in different settings emphasizes the significance of the couple-based interventions. Studies proved that participation of fathers in counseling sessions during antenatal period improved communication and emotional support between partners. At the international level, the effectiveness of couple-based cognitive behavioral therapy and psycho education in reducing the conflicts and increasing mutual understanding was proved. Considering the situation in India, the implementation of relationship counseling in the obstetric services will allow considering the psychological state of the father along with the mother (Chutke*et al*., 2022).

Benefits of Psychoeducation and Self-Care

The descriptive reviewis based on the role played by psychoeducation and self-care in developing paternal resilience. As noted in a systematic review conducted in 11 different countries in 2026, psycho educational interventions significantly reduced the level of paternal anxiety and increased coping skills. Psychoeducation entails providing information to the fathers on the changes experienced during pregnancy, stress management techniques, and self-care such as ensuring one gets enough rest, engaging in exercise, and being mindful. The research findings in India show that the men do not understand how to look after themselves since mostly, they have no idea of how to access services to help them manage the mental illnesses. Community interventions carried out in Kerala showed that through psycho educational interventions, there was an increase in bonding between the fathers and the infants while reducing the stigma on paternal mental illnesses (P Suseela*et al*., 2022). This shows that thedescriptive review information suggests the need for incorporating psychoeducation in general obstetric care in India.

DISCUSSION

From the above analysis, one of the most important aspects is the recognition of the need for the intervention in perinatal mental health of fathers based on cultural relevance and the evidence-based practice (Watkins*et al*., 2024). From the descriptive review literature, there is enough evidence to prove high levels of depression and anxiety among Indian fathers due to financial challenges, stress because of the work-life balance issues and lack of adequate social support. This is a challenge that impacts not only the fathers but also the mothers and even the children which brings out the generational nature of the problem. In addition, there is sufficient evidence on the role of the work-life conflict and marital stress in causing the increase in psychological distress and lack of adequate social support structures to help overcome the challenges. However, interventions such as peer group support, counseling and other interventions at the workplace have been found effective internationally and also locally in India (Agarwal, Brooks& Greenberg, 2020). Finally, there is the aspect of the need for psycho education and self-care as the major coping and engagement strategies.

CONCLUSION

From the results of the current study, one can understand that father's mental well-being is an important aspect of family-oriented care which is being neglected in India. Using the methodology of descriptive review research, one can conclude that the main problems faced by the fathers are such issues as depression, anxiety, work-life balance, and relational problems which result in numerous negative consequences for both mothers and their children. There are various proofs that show the importance of having good social support network and using psycho education and self-care in order to increase personal resilience. In addition, the Delphi validation process revealed the fact that a multidisciplinary intervention which includes such specialists as psychiatrists, psychologists, social workers, obstetricians, nurses, and public health professionals can give culturally sensitive recommendations which will allow

fathers to cope with their problems. Consequently, integration of paternal mental health into obstetrics can improve not only psychological state of men but also relationships between parents and the development of children.

ABSTRACT

In this article, we define and study the classes of $\mathbb{A}$-sets, $\mathbb{B}$-sets, $\mathbb{A}_\alpha$-sets and $\mathbb{S}$-sets in interval-valued topological spaces. Using various interval-valued weakly open sets, we obtain new types of interval-valued locally closed sets. In addition, we introduce a generalized form of locally closed sets and examine several of their basic properties and relationships with existing classes of sets.

Keywords: inter-valued $\mathbb{A}$ -sets, inter-valued $\mathbb{B}$ -sets, inter-valued $\mathbb{A}\alpha$-sets and inter valued S-sets and inter-valued locally closed

INTRODUCTION

The concept of interval sets was first introduced by Yao as an effective tool for representing uncertain and imprecise information. Later, Kim *et al.* developed this concept under the name interval-valued sets, treating them as a generalization of classical sets and a special case of interval-valued fuzzy sets. They investigated several types of interval-valued neighborhoods and classified them into different categories, and also studied interval-valued closure and interior operators. More recently, Cheong *et al.* introduced interval-valued relations and examined their properties from a categorical point of view, thereby extending the applications of interval-valued structures in both theoretical mathematics and computational sciences. The main objective of this paper is to introduce the notions of $\mathbb{A}$-

sets, $\mathbb{B}$-sets, $\mathbb{A}_\alpha$-sets and $\mathbb{S}$-sets in interval-valued topological spaces. By using weakly open sets, a new type of decomposition is obtained. Further, we introduce a new class of sets called inter-valued generalized locally closed sets and investigate some of their fundamental properties.

Preliminaries

Throughout this paper (X, τ) (or X) represent interval-valued topological spaces on which no separation axioms are assumed unless otherwise mentioned. For a subset $[\mathcal{M}^-, \mathcal{M}^+]$ of a space (X, τ), $\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+])$ and $\mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+])$ denote the interval-valued closure of $[\mathcal{M}^-, \mathcal{M}^+]$ and the interval-valued interior of $[\mathcal{M}^-, \mathcal{M}^+]$ respectively. We recall the following definitions which are useful in the sequel.

Definition 2.1: Let X be a non-empty set. Then, the form $[\mathcal{M}^-, \mathcal{M}^+] = \{[\mathcal{S} \subset X: \mathcal{M}^- \subset \mathcal{S} \subset \mathcal{M}^+\}$ is called an interval-valued set (briefly, $\mathcal{IVS}$) in X, if $\mathcal{M}^-, \mathcal{M}^+ \subset X$ and $\mathcal{M}^- \subset \mathcal{M}^+$. In this case, $\mathcal{M}^-$ [resp. $\mathcal{M}^+$] represent the set of minimum [resp. maximum] memberships of elements of X to $[\mathcal{M}^-, \mathcal{M}^+]$. Here, $[\varnothing, \varnothing]$[resp. $[X, X]$] is called the interval-valued empty [resp. whole] set in X and denoted by $\tilde{\varnothing}$ [resp. $\tilde{X}$] The set of all $\mathcal{IVS}$s in X is denoted by $\mathcal{IVS}(X)$. interval valued topological spaces by is denoted by $\mathcal{IVTS}$ or $\mathcal{T}^X$.

Definition 2.2: A non-empty set X with $[\mathcal{M}^-, \mathcal{M}^+]$ and $[\mathcal{S}^-, \mathcal{S}^+]$ are $\mathcal{IVS}$ respectively. Then

- $[\mathcal{M}^-, \mathcal{M}^+] \subset [\mathcal{S}^-, \mathcal{S}^+] \Leftrightarrow \mathcal{M}^- \subset \mathcal{S}^-$ and $\mathcal{M}^+ \subset \mathcal{S}^+$
- $[\mathcal{M}^-, \mathcal{M}^+] = [\mathcal{S}^-, \mathcal{S}^+] \Leftrightarrow [\mathcal{M}^-, \mathcal{M}^+] \subset [\mathcal{S}^-, \mathcal{S}^+]$ and $[\mathcal{S}^-, \mathcal{S}^+] \subset [\mathcal{M}^-, \mathcal{M}^+]$
- $([\mathcal{M}^-, \mathcal{M}^+])^c = [(\mathcal{M}^+)^c, (\mathcal{M}^-)^c]$
- $[\mathcal{M}^-, \mathcal{M}^+] \cup [\mathcal{S}^-, \mathcal{S}^+] = [\mathcal{M}^- \cup \mathcal{S}^-, \mathcal{M}^+ \cup \mathcal{S}^+]$
- $[\mathcal{M}^-, \mathcal{M}^+] \cap [\mathcal{S}^-, \mathcal{S}^+] = [\mathcal{M}^- \cap \mathcal{S}^-, \mathcal{M}^+ \cap \mathcal{S}^+]$

Definition 2.3: Let X be a non-empty set and let τ be a non-empty family of $\mathcal{IVS}$s on X. Then τ is called an interval-valued topology (briefly, $\mathcal{IVT}$) on X if it satisfies the following axioms:

- $\tilde{\varnothing}, [X, X] \in \tau$,
- $[\mathcal{M}^-, \mathcal{M}^+] \cap [\mathcal{S}^-, \mathcal{S}^+] \in \tau$ for any $[\mathcal{M}^-, \mathcal{M}^+], [\mathcal{S}^-, \mathcal{S}^+] \in \tau$.
- $\cup_{j\in J}\mathcal{S}_j \in \tau$ for any family $(\mathcal{S}_j)_{j\in J}$ of members of τ.

In this case, the $\mathcal{T}^X$ is called an interval-valued topological space (briefly, $\mathcal{IVTS}$) and each member of τ is called an interval-valued open set (briefly, $\mathcal{IVO}$s) in X. A $\mathcal{IVS}$ of $[\mathcal{M}^-, \mathcal{M}^+]$ is called an $\mathcal{IV}$-closed set (briefly, $\mathcal{IVC}$s) in X.

Definition 2.4: If a space $\mathcal{T}^X$ with respect to X and if $[\mathcal{M}^-, \mathcal{M}^+] \subseteq \tilde{X}$, then

- The an interval-valued interior of $[\mathcal{M}^-, \mathcal{M}^+]$ is defined as the union of all an interval-valued open subsets of $[\mathcal{M}^-, \mathcal{M}^+]$ and it is denoted by $\mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+])$.
  That is, $\mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+])$ is the largest an interval-valued open subset of $[\mathcal{M}^-, \mathcal{M}^+]$.
- The an interval-valued closure of $[\mathcal{M}^-, \mathcal{M}^+]$ is defined as the intersection of all an $\mathcal{IV}$-closed sets containing $[\mathcal{M}^-, \mathcal{M}^+]$ and it is denoted by $\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+])$.
  That is, $\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+])$ is the smallest an $\mathcal{IV}$-closed set containing $[\mathcal{M}^-, \mathcal{M}^+]$.

Definition 2.5: A subset $[\mathcal{M}^-, \mathcal{M}^+]$ of a space $\mathcal{T}^X$ is called an

- interval-valued pre-open set (briefly, $\mathcal{IV}$p-open) if$[\mathcal{M}^-, \mathcal{M}^+] \subseteq \mathcal{IVI}(\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+]))$.
- $\mathcal{IV}$s-open set (briefly, $\mathcal{IV}$s-open) if$[\mathcal{M}^-, \mathcal{M}^+] \subseteq \mathcal{IVC}(\mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+]))$.
- Interval-valued α-open (briefly, $\mathcal{IV}$α-open) if $[\mathcal{M}^-, \mathcal{M}^+] \subseteq \mathcal{IVI}\left(\mathcal{IVC}(\mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+]))\right)$.
- Interval-valued β-open (briefly, $\mathcal{IV}$β-open) if $[\mathcal{M}^-, \mathcal{M}^+] \subseteq \mathcal{IVC}\left(\mathcal{IVI}(\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+]))\right)$.
- Interval-valued regular-open (resp. $\mathcal{IV}$r-open) if $[\mathcal{M}^-, \mathcal{M}^+] = \mathcal{IVI}(\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+]))$.
- Interval-valued t-set (briefly, $\mathcal{IV}$t-set) if $\mathcal{IVI}(\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+])) = \mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+])$.

Definition 2.6: A subset $[\mathcal{M}^-, \mathcal{M}^+]$ of a space $\mathcal{T}^X$ is called an

- Interval-valued generalized closed (briefly, $\mathcal{IV}$g-closed) if$\mathcal{IV}C([\mathcal{M}^-, \mathcal{M}^+]) \subseteq [\mathcal{K}^-, \mathcal{K}^+]$, whenever $[\mathcal{M}^-, \mathcal{M}^+] \subseteq [\mathcal{K}^-, \mathcal{K}^+]$ and $[\mathcal{K}^-, \mathcal{K}^+]$ is $\mathcal{IV}$-open.
- Interval-valued generalized semi closed (briefly, $\mathcal{IV}$gs-closed) if$\mathcal{IV}sC([\mathcal{M}^-, \mathcal{M}^+]) \subseteq [\mathcal{K}^-, \mathcal{K}^+]$, whenever $[\mathcal{M}^-, \mathcal{M}^+] \subseteq [\mathcal{K}^-, \mathcal{K}^+]$ and $[\mathcal{K}^-, \mathcal{K}^+]$ is $\mathcal{IV}$-open.
- Interval-valued generalized pre closed (briefly, $\mathcal{IV}$gp-closed) if$\mathcal{IV}pC([\mathcal{M}^-, \mathcal{M}^+]) \subseteq [\mathcal{K}^-, \mathcal{K}^+]$, whenever $[\mathcal{M}^-, \mathcal{M}^+] \subseteq [\mathcal{K}^-, \mathcal{K}^+]$ and $[\mathcal{K}^-, \mathcal{K}^+]$ is $\mathcal{IV}$-open.

Definition 2.7. A subset $[\mathcal{M}^-, \mathcal{M}^+]$ of an interval-valued topological space $\mathcal{T}^X$ is said to be interval-valued weakly closed (briefly, $\mathcal{IV}$w-closed) if$\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+]) \subseteq [\mathcal{S}^-, \mathcal{S}^+]$ whenever $[\mathcal{M}^-, \mathcal{M}^+] \subseteq [\mathcal{S}^-, \mathcal{S}^+]$ and $[\mathcal{S}^-, \mathcal{S}^+]$ is $\mathcal{IV}$s-open.

Interval-valued weakly closed and locally closed sets

Definition 3.1: Let $\mathcal{T}^X$ be a interval-valued topological space and $[\mathcal{M}^-, \mathcal{M}^+] \subseteq \tilde{X}$. Then $[\mathcal{M}^-, \mathcal{M}^+]$ is said to be an

- Interval-valued $\mathbb{A}$-set (briefly, $\mathcal{IV}\mathbb{A}$-set) if $[\mathcal{M}^-, \mathcal{M}^+] = [\mathcal{K}^-, \mathcal{K}^+] \cap [\mathcal{S}^-, \mathcal{S}^+]$ where $[\mathcal{K}^-, \mathcal{K}^+]$ is $\mathcal{IV}$-open and $[\mathcal{S}^-, \mathcal{S}^+]$ is $\mathcal{IV}$r-closed.
- Interval-valued $\mathbb{B}$-set (briefly, $\mathcal{IV}\mathbb{B}$-set) if $[\mathcal{M}^-, \mathcal{M}^+] = [\mathcal{K}^-, \mathcal{K}^+] \cap [\mathcal{S}^-, \mathcal{S}^+]$ where $[\mathcal{K}^-, \mathcal{K}^+]$ is $\mathcal{IV}$-open and $[\mathcal{S}^-, \mathcal{S}^+]$ is $\mathcal{IV}$t-set.
- Interval-valued $\mathbb{A}_\alpha$-set (briefly, $\mathcal{IV}\mathbb{A}_\alpha$-set) if $[\mathcal{M}^-, \mathcal{M}^+] = [\mathcal{K}^-, \mathcal{K}^+] \cap [\mathcal{S}^-, \mathcal{S}^+]$ where $[\mathcal{K}^-, \mathcal{K}^+]$ is $\mathcal{IV}\alpha$-open and $[\mathcal{S}^-, \mathcal{S}^+]$ is $\mathcal{IV}$r-closed.
- Interval-valued $\mathbb{S}$-set (briefly, $\mathcal{IV}\mathbb{S}$-set) if $[\mathcal{M}^-, \mathcal{M}^+] = [\mathcal{K}^-, \mathcal{K}^+] \cap [\mathcal{S}^-, \mathcal{S}^+]$ where $[\mathcal{K}^-, \mathcal{K}^+]$ is $\mathcal{IV}$s-open and $[\mathcal{S}^-, \mathcal{S}^+]$ is $\mathcal{IV}$-closed.

Theorem 3.2: Let $\mathcal{T}^X$ be an interval-valued topological space. Then the following statements hold:

- Every $\mathcal{IV}$-closed set is an $\mathcal{IV}$t-set.
- Every $\mathcal{IV}$t-set is an $\mathcal{IV}\mathbb{B}$-set.
- Every $\mathcal{IV}\mathbb{A}$-set is an $\mathcal{IV}\mathbb{S}$-set.
- Every $\mathcal{IV}\mathbb{A}_\alpha$-set is an $\mathcal{IV}\mathbb{S}$-set.
- Every $\mathcal{IV}$s-open set is an $\mathcal{IV}\mathbb{S}$-set.

Proof:

- Let $[\mathcal{M}^-, \mathcal{M}^+]$ be an $\mathcal{IV}$-closed set. Then $\mathcal{IVI}\big(\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+])\big) = \mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+])$. Hence $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$t-set.
- Let $[\mathcal{M}^-, \mathcal{M}^+]$ be an $\mathcal{IV}$t-set. Since $\tilde{X}$ is $\mathcal{IV}$-open, we have $[\mathcal{M}^-, \mathcal{M}^+] = \tilde{X} \cap [\mathcal{M}^-, \mathcal{M}^+]$, where $\tilde{X}$ is $\mathcal{IV}$-open and $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$t-set. Therefore, $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{B}$-set.
- Let $[\mathcal{M}^-, \mathcal{M}^+]$ be an $\mathcal{IV}\mathbb{A}$-set. Then $[\mathcal{M}^-, \mathcal{M}^+] = [\mathcal{K}^-, \mathcal{K}^+] \cap [\mathcal{S}^-, \mathcal{S}^+]$, where $[\mathcal{K}^-, \mathcal{K}^+]$ is $\mathcal{IV}$-open and $[\mathcal{S}^-, \mathcal{S}^+]$ is $\mathcal{IV}$r-closed. Since every $\mathcal{IV}$-open set is $\mathcal{IV}$s-open and every $\mathcal{IV}$r-closed set is $\mathcal{IV}$-closed, it follows that $[\mathcal{M}^-, \mathcal{M}^+] = [\mathcal{K}^-, \mathcal{K}^+] \cap [\mathcal{S}^-, \mathcal{S}^+]$, where $[\mathcal{K}^-, \mathcal{K}^+]$ is $\mathcal{IV}$s-open and $[\mathcal{S}^-, \mathcal{S}^+]$ is $\mathcal{IV}$-closed. Hence $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{S}$-set.
- Let $[\mathcal{M}^-, \mathcal{M}^+]$ be an $\mathcal{IV}\mathbb{A}_\alpha$-set. Then $[\mathcal{M}^-, \mathcal{M}^+] = [\mathcal{K}^-, \mathcal{K}^+] \cap [\mathcal{S}^-, \mathcal{S}^+]$, where $[\mathcal{K}^-, \mathcal{K}^+]$ is $\mathcal{IV}\alpha$-open and $[\mathcal{S}^-, \mathcal{S}^+]$ is $\mathcal{IV}$r-closed. Since every $\mathcal{IV}\alpha$-open set is $\mathcal{IV}$s-open and every $\mathcal{IV}$r-closed set is $\mathcal{IV}$-closed, we obtain that $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{S}$-set.
- Let $[\mathcal{M}^-, \mathcal{M}^+]$ be an $\mathcal{IV}$s-open set. Then $[\mathcal{M}^-, \mathcal{M}^+] = [\mathcal{M}^-, \mathcal{M}^+] \cap \tilde{X}$, where $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$s-open and $\tilde{X}$ is $\mathcal{IV}$-closed. Therefore, $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{S}$-set.

Example 3.3: Consider the interval-valued topological space $X = \{a, b\}$ with $\tau = \{\tilde{X}, \tilde{\varnothing}, [\varnothing, \{a\}], [\{a\}, X]\}$. Then we have the following:

- The set $[\varnothing, \{a\}]$ is an $\mathcal{IV}$t-set, whereas it is not an $\mathcal{IV}$-closed.
- The set $[\{a\}, \{a, b\}]$ is an $\mathcal{IV}\mathbb{B}$-set, but it fails to be an $\mathcal{IV}$t-set.
- The set $[\varnothing, \{b\}]$ is an $\mathcal{IV}\mathbb{S}$-set, but it fails to be an $\mathcal{IV}\mathbb{A}$-set.
- The set $[\varnothing, \{b\}]$ is an $\mathcal{IV}\mathbb{S}$-set, but it fails to be an $\mathcal{IV}$s-open.
- The set $[\varnothing, \{b\}]$ is an $\mathcal{IV}\mathbb{S}$-set, but it fails to be an $\mathcal{IV}\mathbb{A}_\alpha$-set.

Theorem 3.4: Let $\mathcal{T}^X$ be an interval-valued topological space and $[\mathcal{M}^-, \mathcal{M}^+] \subseteq \widetilde{X}$. Then the following statements hold:

- $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$t-set if and only if it is $\mathcal{IV}$s-closed.
- $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$r-open if and only if $[\mathcal{M}^-, \mathcal{M}^+]$ is both $\mathcal{IV}$p-open and an $\mathcal{IV}$t-set.
- If $[\mathcal{M}^-, \mathcal{M}^+]$ and $[\mathcal{K}^-, \mathcal{K}^+]$ are two $\mathcal{IV}$t-sets, then $[\mathcal{M}^-, \mathcal{M}^+] \cap [\mathcal{K}^-, \mathcal{K}^+]$ is also an $\mathcal{IV}$t-set.

Proof:

- Suppose that $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$t-set. Then $\mathcal{IVI}(\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+])) = \mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+])$. Taking complements on both sides, we obtain $\mathcal{IVC}(\mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+])) = \mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+])$, and hence $\mathcal{IVC}(\mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+])) \subseteq [\mathcal{M}^-, \mathcal{M}^+]$. Therefore, $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$s-closed. Conversely, assume that $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$s-closed. Then $\mathcal{IVC}(\mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+])) \subseteq [\mathcal{M}^-, \mathcal{M}^+]$. Applying the operator $\mathcal{IVI}$ on both sides, we get $\mathcal{IVI}\left(\mathcal{IVC}(\mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+]))\right) \subseteq \mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+])$. Since $\mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+]) \subseteq \mathcal{IVI}(\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+]))$, it follows that $\mathcal{IVI}(\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+])) = \mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+])$. Hence $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$t-set.
- Assume that $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$r-open. Then $[\mathcal{M}^-, \mathcal{M}^+] = \mathcal{IVI}(\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+]))$. Hence $[\mathcal{M}^-, \mathcal{M}^+] \subseteq \mathcal{IVI}(\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+]))$, and therefore $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$p-open. Also, $\mathcal{IVI}(\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+])) = [\mathcal{M}^-, \mathcal{M}^+] = \mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+])$, which shows that $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$t-set. Conversely, suppose that $[\mathcal{M}^-, \mathcal{M}^+]$ is both $\mathcal{IV}$p-open and an $\mathcal{IV}$t-set. Since it is $\mathcal{IV}$p-open, $[\mathcal{M}^-, \mathcal{M}^+] \subseteq \mathcal{IVI}(\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+]))$. Again, as it is an $\mathcal{IV}$t-set, $\mathcal{IVI}(\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+])) = \mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+]) \subseteq [\mathcal{M}^-, \mathcal{M}^+]$. Therefore, $[\mathcal{M}^-, \mathcal{M}^+] = \mathcal{IVI}(\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+]))$. Hence $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$r-open.
- Let $[\mathcal{M}^-, \mathcal{M}^+]$ and $[\mathcal{K}^-, \mathcal{K}^+]$ be two $\mathcal{IV}$t-sets. Since $\mathcal{IVI}(\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+])) = \mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+])$ and $\mathcal{IVI}(\mathcal{IVC}([\mathcal{K}^-, \mathcal{K}^+])) = \mathcal{IVI}([\mathcal{K}^-, \mathcal{K}^+])$, we obtain $\mathcal{IVI}(\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+] \cap [\mathcal{K}^-, \mathcal{K}^+])) = \mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+] \cap [\mathcal{K}^-, \mathcal{K}^+])$. Hence $[\mathcal{M}^-, \mathcal{M}^+] \cap [\mathcal{K}^-, \mathcal{K}^+]$ is an $\mathcal{IV}$t-set.

Theorem 3.5: For a subset $[\mathcal{M}^-, \mathcal{M}^+]$ of a interval-valued topological space $\mathcal{T}^X$, the following are equivalent:

- $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$-open.
- $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$p-open and $\mathcal{IV}\mathbb{B}$-set.

Proof.(1) ⇒ (2): Assume that $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$-open. Since every $\mathcal{IV}$-open set is $\mathcal{IV}$p-open, we have $[\mathcal{M}^-, \mathcal{M}^+] \subseteq \mathcal{IVI}(\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+]))$. Also, every $\mathcal{IV}$-open set is an $\mathcal{IV}$t-set. Hence $\mathcal{IVI}(\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+])) = \mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+])$. Now, $[\mathcal{M}^-, \mathcal{M}^+] = \widetilde{X} \cap [\mathcal{M}^-, \mathcal{M}^+]$, where $\widetilde{X}$ is $\mathcal{IV}$-open and $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$t-set. Therefore, $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{B}$-set.

(2) ⇒ (1): Assume that $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$p-open and an $\mathcal{IV}\mathbb{B}$-set. Since it is an $\mathcal{IV}\mathbb{B}$-set, there exist $[\mathcal{K}^-, \mathcal{K}^+]$ and $[\mathcal{S}^-, \mathcal{S}^+]$ such that $[\mathcal{M}^-, \mathcal{M}^+] = [\mathcal{K}^-, \mathcal{K}^+] \cap [\mathcal{S}^-, \mathcal{S}^+]$, where $[\mathcal{K}^-, \mathcal{K}^+]$ is $\mathcal{IV}$-open and $[\mathcal{S}^-, \mathcal{S}^+]$ is an $\mathcal{IV}$t-set. Since $[\mathcal{S}^-, \mathcal{S}^+]$ is an $\mathcal{IV}$t-set, $\mathcal{IVI}(\mathcal{IVC}([\mathcal{S}^-, \mathcal{S}^+])) = \mathcal{IVI}([\mathcal{S}^-, \mathcal{S}^+])$. Also, as $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$p-open, $[\mathcal{M}^-, \mathcal{M}^+] \subseteq \mathcal{IVI}(\mathcal{IVC}([\mathcal{M}^-, \mathcal{M}^+]))$. Using $[\mathcal{M}^-, \mathcal{M}^+] = [\mathcal{K}^-, \mathcal{K}^+] \cap [\mathcal{S}^-, \mathcal{S}^+]$, we get $[\mathcal{M}^-, \mathcal{M}^+] = [\mathcal{K}^-, \mathcal{K}^+] \cap \mathcal{IVI}([\mathcal{S}^-, \mathcal{S}^+])$. Since the intersection of two $\mathcal{IV}$-open sets is $\mathcal{IV}$-open, it follows that $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$-open.

Remark 3.6: In general, the union of two $\mathcal{IV}$t-sets is not necessarily an $\mathcal{IV}$t-set.

Example 3.7:

Consider the interval-valued topological space $X = \{a, b, c\}$ with $\tau = \{\widetilde{X}, \tilde{\varnothing}, [\varnothing, \{a\}], [\varnothing, \{b\}], [\varnothing, \{a, b\}], [\{a\}, X]\}$.
The sets $[\varnothing, \{a, b\}]$ and $[\varnothing, \{b, c\}]$ are $\mathcal{IV}$t-sets, but their union $[\varnothing, \{a, b\}] \cup [\varnothing, \{b, c\}] = [\varnothing, X]$ is not an $\mathcal{IV}$t-set.

Theorem 3.8: The intersection of an $\mathcal{IV}$s-open set and an $\mathcal{IV}\alpha$-open set is an $\mathcal{IV}$s-open set.

Proof. Let $[\mathcal{M}^-, \mathcal{M}^+]$ be an $\mathcal{IV}$s-open set and $[\mathcal{K}^-, \mathcal{K}^+]$ be an $\mathcal{IV}\alpha$-open set. Since $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$s-open, $[\mathcal{M}^-, \mathcal{M}^+] \subseteq \mathcal{IVC}(\mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+]))$. Also, since $[\mathcal{K}^-, \mathcal{K}^+]$ is $\mathcal{IV}\alpha$-open, we have $[\mathcal{K}^-, \mathcal{K}^+] \subseteq \mathcal{IVI}\left(\mathcal{IVC}(\mathcal{IVI}([\mathcal{K}^-, \mathcal{K}^+]))\right)$.
Since every $\mathcal{IV}\alpha$-open set is $\mathcal{IV}$s-open, $[\mathcal{K}^-, \mathcal{K}^+] \subseteq \mathcal{IVC}(\mathcal{IVI}([\mathcal{K}^-, \mathcal{K}^+]))$.
Hence,
$[\mathcal{M}^-, \mathcal{M}^+] \cap [\mathcal{K}^-, \mathcal{K}^+] \subseteq \mathcal{IVC}(\mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+])) \cap \mathcal{IVC}(\mathcal{IVI}([\mathcal{K}^-, \mathcal{K}^+])) = \mathcal{IVC}(\mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+]) \cap \mathcal{IVI}([\mathcal{K}^-, \mathcal{K}^+])) = \mathcal{IVC}(\mathcal{IVI}([\mathcal{M}^-, \mathcal{M}^+] \cap [\mathcal{K}^-, \mathcal{K}^+]))$. Therefore, $[\mathcal{M}^-, \mathcal{M}^+] \cap [\mathcal{K}^-, \mathcal{K}^+]$ is an $\mathcal{IV}$s-open set.

Theorem 3.9: Let $\mathcal{T}^X$ be an interval-valued topological space. Then the following statements hold:

- Every $\mathcal{IV}\mathbb{A}$-set is an $\mathcal{IV}\mathbb{A}_\alpha$-set.

- Every $\mathcal{IV}\mathbb{A}_\alpha$-set is $\mathcal{IV}$s-open.
- Every $\mathcal{IV}\mathbb{A}_\alpha$-set is $\mathcal{IV}\beta$-open.
- Every $\mathcal{IV}\mathbb{A}$-set is an $\mathcal{IV}\mathbb{B}$-set.

Proof:
(1) Let $[\mathcal{M}^-,\mathcal{M}^+]$ be an $\mathcal{IV}\mathbb{A}$-set. Since every $\mathcal{IV}$-open set is $\mathcal{IV}\alpha$-open, $[\mathcal{M}^-,\mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{A}_\alpha$-set. (2) Let $[\mathcal{M}^-,\mathcal{M}^+]$ be an $\mathcal{IV}\mathbb{A}_\alpha$-set. Since every $\mathcal{IV}\alpha$-open set is $\mathcal{IV}$s-open and every $\mathcal{IV}$r-closed set is $\mathcal{IV}$-closed, $[\mathcal{M}^-,\mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{S}$-set and therefore $\mathcal{IV}$s-open. (3) By (2), every $\mathcal{IV}\mathbb{A}_\alpha$-set is $\mathcal{IV}$s-open. Since every $\mathcal{IV}$s-open set is $\mathcal{IV}\beta$-open, it follows that every $\mathcal{IV}\mathbb{A}_\alpha$-set is $\mathcal{IV}\beta$-open. (4) Let $[\mathcal{M}^-,\mathcal{M}^+]$ be an $\mathcal{IV}\mathbb{A}$-set. Since every $\mathcal{IV}$r-closed set is an $\mathcal{IV}$t-set, $[\mathcal{M}^-,\mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{B}$-set.

Definition 3.10: Let $\mathcal{T}^{\mathrm{X}}$ be an interval-valued topological space and $[\mathcal{M}^-,\mathcal{M}^+] \subseteq \widetilde{\mathrm{X}}$. Then $[\mathcal{M}^-,\mathcal{M}^+]$ is said to be an
- Interval-valued locally closed set (briefly, $\mathcal{IV}$l-closed set) if $[\mathcal{M}^-,\mathcal{M}^+] = [\mathcal{K}^-,\mathcal{K}^+] \cap [\mathcal{S}^-,\mathcal{S}^+]$, where $[\mathcal{K}^-,\mathcal{K}^+]$ is $\mathcal{IV}$-open and $[\mathcal{S}^-,\mathcal{S}^+]$ is $\mathcal{IV}$-closed.
- Interval-valued weakly locally* closed set (briefly, $\mathcal{IV}$wl*-closed set) if $[\mathcal{M}^-,\mathcal{M}^+] = [\mathcal{K}^-,\mathcal{K}^+] \cap [\mathcal{S}^-,\mathcal{S}^+]$, where $[\mathcal{K}^-,\mathcal{K}^+]$ is $\mathcal{IV}$w-open and $[\mathcal{S}^-,\mathcal{S}^+]$ is $\mathcal{IV}$-closed.
- Interval-valued weakly t-set (briefly, $\mathcal{IV}$wt-set) if $[\mathcal{M}^-,\mathcal{M}^+] = [\mathcal{K}^-,\mathcal{K}^+] \cap [\mathcal{S}^-,\mathcal{S}^+]$, where $[\mathcal{K}^-,\mathcal{K}^+]$ is $\mathcal{IV}$w-open and $[\mathcal{S}^-,\mathcal{S}^+]$ is $\mathcal{IV}$t-set.

Theorem 3.11: Let $[\mathcal{M}^-,\mathcal{M}^+] \subset \widetilde{\mathrm{X}}$ be a interval-valued topological space $\mathcal{T}^{\mathrm{X}}$. Then the following are equivalent.
- $[\mathcal{M}^-,\mathcal{M}^+]$ is a $\mathcal{IV}\mathbb{A}$-set.
- $[\mathcal{M}^-,\mathcal{M}^+]$ is $\mathcal{IV}\mathbb{A}_\alpha$-set and $\mathcal{IV}$l-closed.
- $[\mathcal{M}^-,\mathcal{M}^+]$ is $\mathcal{IV}$s-open and $\mathcal{IV}$l-closed.

Proof:
(1) ⇒ (2): Assume that $[\mathcal{M}^-,\mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{A}$-set. Since every $\mathcal{IV}$-open set is $\mathcal{IV}\alpha$-open, $[\mathcal{M}^-,\mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{A}_\alpha$-set. Also, every $\mathcal{IV}$r-closed set is $\mathcal{IV}$-closed. Hence $[\mathcal{M}^-,\mathcal{M}^+]$ is $\mathcal{IV}$l-closed.
(2) ⇒ (3): Assume that $[\mathcal{M}^-,\mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{A}_\alpha$-set and $\mathcal{IV}$l-closed. Since every $\mathcal{IV}\mathbb{A}_\alpha$-set is $\mathcal{IV}$s-open, $[\mathcal{M}^-,\mathcal{M}^+]$ is $\mathcal{IV}$s-open and $\mathcal{IV}$l-closed.
(3) ⇒ (1): Assume that $[\mathcal{M}^-,\mathcal{M}^+]$ is $\mathcal{IV}$s-open and $\mathcal{IV}$l-closed. Since $[\mathcal{M}^-,\mathcal{M}^+]$ is $\mathcal{IV}$l-closed, there exist $[\mathcal{K}^-,\mathcal{K}^+]$ and $[\mathcal{S}^-,\mathcal{S}^+]$ such that $[\mathcal{M}^-,\mathcal{M}^+] = [\mathcal{K}^-,\mathcal{K}^+] \cap [\mathcal{S}^-,\mathcal{S}^+]$, where $[\mathcal{K}^-,\mathcal{K}^+]$ is $\mathcal{IV}$-open and $[\mathcal{S}^-,\mathcal{S}^+]$ is $\mathcal{IV}$-closed. Since every $\mathcal{IV}$-closed set is $\mathcal{IV}$r-closed, we obtain that $[\mathcal{M}^-,\mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{A}$-set.

Theorem 3.12: Let $[\mathcal{M}^-,\mathcal{M}^+]$ be a subset of the interval-valued topological space $\mathcal{T}^{\mathrm{X}}$. Then $[\mathcal{M}^-,\mathcal{M}^+]$ is $\mathcal{IV}$-closed if and only if it possesses both the properties of $\mathcal{IV}$w-closedness and an $\mathcal{IV}\mathbb{S}$-set.

Proof:
Suppose that $[\mathcal{M}^-,\mathcal{M}^+]$ is $\mathcal{IV}$-closed. Since every $\mathcal{IV}$-closed set is trivially $\mathcal{IV}$w-closed, $[\mathcal{M}^-,\mathcal{M}^+]$ is $\mathcal{IV}$w-closed. Further, $[\mathcal{M}^-,\mathcal{M}^+] = \widetilde{\mathrm{X}} \cap [\mathcal{M}^-,\mathcal{M}^+]$, where $\widetilde{\mathrm{X}}$ is $\mathcal{IV}$s-open and $[\mathcal{M}^-,\mathcal{M}^+]$ is $\mathcal{IV}$-closed. Hence $[\mathcal{M}^-,\mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{S}$-set. Conversely, assume that $[\mathcal{M}^-,\mathcal{M}^+]$ is both $\mathcal{IV}$w-closed and an $\mathcal{IV}\mathbb{S}$-set. Since it is an $\mathcal{IV}\mathbb{S}$-set, there exist an $\mathcal{IV}$s-open set $[\mathcal{G}^-,\mathcal{G}^+]$ and an $\mathcal{IV}$-closed set $[\mathcal{F}^-,\mathcal{F}^+]$ such that $[\mathcal{M}^-,\mathcal{M}^+] = [\mathcal{G}^-,\mathcal{G}^+] \cap [\mathcal{F}^-,\mathcal{F}^+]$. Thus, $[\mathcal{M}^-,\mathcal{M}^+] \subseteq [\mathcal{F}^-,\mathcal{F}^+]$. Since $[\mathcal{F}^-,\mathcal{F}^+]$ is $\mathcal{IV}$-closed, it is also $\mathcal{IV}$s-open. As $[\mathcal{M}^-,\mathcal{M}^+]$ is $\mathcal{IV}$w-closed and $[\mathcal{M}^-,\mathcal{M}^+] \subseteq [\mathcal{F}^-,\mathcal{F}^+]$, we obtain $\mathcal{IVC}([\mathcal{M}^-,\mathcal{M}^+]) \subseteq [\mathcal{F}^-,\mathcal{F}^+]$. But $[\mathcal{F}^-,\mathcal{F}^+] \subseteq \mathcal{IVC}([\mathcal{M}^-,\mathcal{M}^+])$, because $[\mathcal{F}^-,\mathcal{F}^+]$ is a closed set containing $[\mathcal{M}^-,\mathcal{M}^+]$. Therefore, $\mathcal{IVC}([\mathcal{M}^-,\mathcal{M}^+]) = [\mathcal{M}^-,\mathcal{M}^+]$. Hence $[\mathcal{M}^-,\mathcal{M}^+]$ is $\mathcal{IV}$-closed.

Theorem 3.13: Let $[\mathcal{M}^-,\mathcal{M}^+]$ be a subset of an interval-valued topological space $\mathcal{T}^{\mathrm{X}}$. Then the following statements are equivalent:
- $[\mathcal{M}^-,\mathcal{M}^+]$ is $\mathcal{IV}$-closed.
- $[\mathcal{M}^-,\mathcal{M}^+]$ is both $\mathcal{IV}$l-closed and $\mathcal{IV}$w-closed.
- $[\mathcal{M}^-,\mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{S}$-set and also $\mathcal{IV}$w-closed.

Proof:
(1) ⇒ (2): Assume that $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$-closed. Since every $\mathcal{IV}$-closed set is $\mathcal{IV}$w-closed and $[\mathcal{M}^-, \mathcal{M}^+] = \widetilde{X} \cap [\mathcal{M}^-, \mathcal{M}^+]$ where $\widetilde{X}$ is $\mathcal{IV}$-open, $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$l-closed and $\mathcal{IV}$w-closed.
(2) ⇒ (3): Assume that $[\mathcal{M}^-, \mathcal{M}^+]$ is both $\mathcal{IV}$l-closed and $\mathcal{IV}$w-closed. Since $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$l-closed, there exist an $\mathcal{IV}$-open set $[\mathcal{G}^-, \mathcal{G}^+]$ and an $\mathcal{IV}$-closed set $[\mathcal{F}^-, \mathcal{F}^+]$ such that $[\mathcal{M}^-, \mathcal{M}^+] = [\mathcal{G}^-, \mathcal{G}^+] \cap [\mathcal{F}^-, \mathcal{F}^+]$. Since every $\mathcal{IV}$-open set is $\mathcal{IV}$s-open, $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{S}$-set.
(3) ⇒ (1): By the previous theorem, $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$-closed.

Theorem 3.14: Let $[\mathcal{M}^-, \mathcal{M}^+]$ be a subset of an interval-valued topological space $\mathcal{T}^X$. Then the following statements hold:
- If $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$w-open, then $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$wlc*-set.
- If $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$-closed, then $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$wlc*-set.
- If $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$t-set, then $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$wt-set.

Proof:
(1) Assume that $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$w-open. Then $[\mathcal{M}^-, \mathcal{M}^+] = [\mathcal{M}^-, \mathcal{M}^+] \cap \widetilde{X}$, where $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$w-open and $\widetilde{X}$ is $\mathcal{IV}$-closed. Hence $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$wlc*-set.
(2) Assume that $[\mathcal{M}^-, \mathcal{M}^+]$ is $\mathcal{IV}$-closed. Since $\widetilde{X}$ is $\mathcal{IV}$w-open and $[\mathcal{M}^-, \mathcal{M}^+] = \widetilde{X} \cap [\mathcal{M}^-, \mathcal{M}^+]$, $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$wlc*-set.
(3) Assume that $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$t-set. Then $[\mathcal{M}^-, \mathcal{M}^+] = \widetilde{X} \cap [\mathcal{M}^-, \mathcal{M}^+]$, where $\widetilde{X}$ is $\mathcal{IV}$w-open and $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$t-set. Hence $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$wt-set.

Theorem 3.15: Let $[\mathcal{M}^-, \mathcal{M}^+]$ be a subset of an interval-valued topological space $\mathcal{T}^X$. Then the following statements hold:
- If $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$wlc*-set, then $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$wt-set.
- If $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{A}$-set, then $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$wlc*-set.
- If $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{A}$-set, then $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$wt-set.
- If $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{B}$-set, then $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$wt-set.

Proof:
(1) Assume that $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$wlc*-set. Then there exist a $\mathcal{IV}$w-open set $[\mathcal{G}^-, \mathcal{G}^+]$ and a $\mathcal{IV}$-closed set $[\mathcal{F}^-, \mathcal{F}^+]$ such that $[\mathcal{M}^-, \mathcal{M}^+] = [\mathcal{G}^-, \mathcal{G}^+] \cap [\mathcal{F}^-, \mathcal{F}^+]$. Since every $\mathcal{IV}$-closed set is an $\mathcal{IV}$t-set, $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$wt-set.
(2) Assume that $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{A}$-set. Since every $\mathcal{IV}$-open set is $\mathcal{IV}$w-open and every $\mathcal{IV}$r-closed set is $\mathcal{IV}$-closed, $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$wlc*-set.
(3) By (2), $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$wlc*-set. By (1), $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$wt-set.
(4) Assume that $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}\mathbb{B}$-set. Since every $\mathcal{IV}$-open set is $\mathcal{IV}$w-open, $[\mathcal{M}^-, \mathcal{M}^+]$ is an $\mathcal{IV}$wt-set.

Interval-valued generalized locally closed sets

Remark 4.1: The following are well known.
- A subset $[\mathcal{M}^-, \mathcal{M}^+]$ of $\mathcal{T}^X$ is $\mathcal{IV}$l-closed if and only if its complement $U - A$ is the union of a $\mathcal{IV}$-open set and a $\mathcal{IV}$-closed set.
- Every $\mathcal{IV}$-open (resp. $\mathcal{IV}$-closed) subset of U is $\mathcal{IV}$l-closed.
- The complement of a $\mathcal{IV}$l-closed set need not be $\mathcal{IV}$l-closed.

Definition 4.2: A subset $[\mathcal{M}^-, \mathcal{M}^+]$ of $\mathcal{T}^X$ is called an
- Interval-valued generalized locally closed set (briefly $\mathcal{IV}$gl-closed) if $[\mathcal{M}^-, \mathcal{M}^+] = [\mathcal{K}^-, \mathcal{K}^+] \cap [\mathcal{S}^-, \mathcal{S}^+]$, where $[\mathcal{K}^-, \mathcal{K}^+]$ is $\mathcal{IV}$g-open and $[\mathcal{S}^-, \mathcal{S}^+]$ is $\mathcal{IV}$g-closed.
- Interval-valued generalized locally* closed set (briefly $\mathcal{IV}$gl*-closed) if $[\mathcal{M}^-, \mathcal{M}^+] = [\mathcal{K}^-, \mathcal{K}^+] \cap [\mathcal{S}^-, \mathcal{S}^+]$, where $[\mathcal{K}^-, \mathcal{K}^+]$ is $\mathcal{IV}$g-open and $[\mathcal{S}^-, \mathcal{S}^+]$ is $\mathcal{IV}$-closed.

- Interval-valued generalized locally** closed set (briefly $\mathcal{IV}$gl**-closed) if $[\mathcal{M}^-,\mathcal{M}^+] = [\mathcal{K}^-,\mathcal{K}^+] \cap [\mathcal{S}^-,\mathcal{S}^+]$, where $[\mathcal{K}^-,\mathcal{K}^+]$ is $\mathcal{IV}$-open and $[\mathcal{S}^-,\mathcal{S}^+]$ is $\mathcal{IV}$g-closed.

Example 4.3: In Example 3.3,
- $\wp(X)$ is $\mathcal{IV}$gl-closed.
- [{b},{b}] is not $\mathcal{IV}$gl*-closed.
- [{a},{a}] is not $\mathcal{IV}$gl**-closed.

Remark 4.46: Every $\mathcal{IV}$g-closed set (respectively, $\mathcal{IV}$g-open set) is $\mathcal{IV}$gl-closed.

Theorem 4.5: Let $[\mathcal{M}^-,\mathcal{M}^+]$ be a subset of an interval-valued topological space $\mathcal{T}^X$. Then the following statements hold:
- If $[\mathcal{M}^-,\mathcal{M}^+]$ is $\mathcal{IV}$l-closed, then $[\mathcal{M}^-,\mathcal{M}^+] \in \mathcal{IV}$gl*-closed.
- If $[\mathcal{M}^-,\mathcal{M}^+] \in \mathcal{IV}$gl*-closed or $[\mathcal{M}^-,\mathcal{M}^+] \in \mathcal{IV}$gl**-closed, then $[\mathcal{M}^-,\mathcal{M}^+]$ is $\mathcal{IV}$gl-closed.

Proof: (1) Assume that $[\mathcal{M}^-,\mathcal{M}^+]$ is $\mathcal{IV}$l-closed. Then there exist a $\mathcal{IV}$-open set $[\mathcal{G}^-,\mathcal{G}^+]$ and a $\mathcal{IV}$-closed set $[\mathcal{F}^-,\mathcal{F}^+]$ such that $[\mathcal{M}^-,\mathcal{M}^+] = [\mathcal{G}^-,\mathcal{G}^+] \cap [\mathcal{F}^-,\mathcal{F}^+]$. Since every $\mathcal{IV}$-open set is $\mathcal{IV}$g-open, $[\mathcal{M}^-,\mathcal{M}^+] \in \mathcal{IV}$gl*-closed.
(2) If $[\mathcal{M}^-,\mathcal{M}^+] \in \mathcal{IV}$gl*-closed, since every $\mathcal{IV}$-closed set is $\mathcal{IV}$g-closed, $[\mathcal{M}^-,\mathcal{M}^+]$ is $\mathcal{IV}$gl-closed. If $[\mathcal{M}^-,\mathcal{M}^+] \in \mathcal{IV}$gl**-closed, since every $\mathcal{IV}$-open set is $\mathcal{IV}$g-open, $[\mathcal{M}^-,\mathcal{M}^+]$ is $\mathcal{IV}$gl-closed.

Theorem 4.6: Let $[\mathcal{M}^-,\mathcal{M}^+]$ be a subset of an interval-valued topological space $\mathcal{T}^X$. Then the following statements are equivalent:
- $[\mathcal{M}^-,\mathcal{M}^+]$ is an $\mathcal{IV}$gl*-closed set.
- There exists an $\mathcal{IV}$g-open set $[\mathcal{S}^-,\mathcal{S}^+]$ such that $[\mathcal{M}^-,\mathcal{M}^+] = [\mathcal{S}^-,\mathcal{S}^+] \cap \mathcal{IVC}([\mathcal{M}^-,\mathcal{M}^+])$.
- $\mathcal{IVC}([\mathcal{M}^-,\mathcal{M}^+]) - [\mathcal{M}^-,\mathcal{M}^+]$ is an $\mathcal{IV}$g-closed set.
- $[\mathcal{M}^-,\mathcal{M}^+] \cup \left(\widetilde{X} - \mathcal{IVC}([\mathcal{M}^-,\mathcal{M}^+])\right)$ is an $\mathcal{IV}$g-open set.

Proof: (1) ⇒ (2): Assume that $[\mathcal{M}^-,\mathcal{M}^+]$ is an $\mathcal{IV}$gl*-closed set. Then there exist an $\mathcal{IV}$g-open set $[\mathcal{S}^-,\mathcal{S}^+]$ and an $\mathcal{IV}$-closed set $[\mathcal{F}^-,\mathcal{F}^+]$ such that $[\mathcal{M}^-,\mathcal{M}^+] = [\mathcal{S}^-,\mathcal{S}^+] \cap [\mathcal{F}^-,\mathcal{F}^+]$. Since $[\mathcal{M}^-,\mathcal{M}^+] \subseteq [\mathcal{F}^-,\mathcal{F}^+]$ and $[\mathcal{F}^-,\mathcal{F}^+]$ is $\mathcal{IV}$-closed, we have $\mathcal{IVC}([\mathcal{M}^-,\mathcal{M}^+]) \subseteq [\mathcal{F}^-,\mathcal{F}^+]$. Thus $[\mathcal{M}^-,\mathcal{M}^+] = [\mathcal{S}^-,\mathcal{S}^+] \cap \mathcal{IVC}([\mathcal{M}^-,\mathcal{M}^+])$.
(2) ⇒ (1): Since $\mathcal{IVC}([\mathcal{M}^-,\mathcal{M}^+])$ is $\mathcal{IV}$-closed, $[\mathcal{M}^-,\mathcal{M}^+]$ is an $\mathcal{IV}$gl*-closed set.
(2) ⇒ (3): From $[\mathcal{M}^-,\mathcal{M}^+] = [\mathcal{S}^-,\mathcal{S}^+] \cap \mathcal{IVC}([\mathcal{M}^-,\mathcal{M}^+])$,
we obtain $\mathcal{IVC}([\mathcal{M}^-,\mathcal{M}^+]) - [\mathcal{M}^-,\mathcal{M}^+] = \mathcal{IVC}([\mathcal{M}^-,\mathcal{M}^+]) \cap [\mathcal{S}^-,\mathcal{S}^+]^c$. Since $[\mathcal{S}^-,\mathcal{S}^+]$ is $\mathcal{IV}$g-open, its complement is $\mathcal{IV}$g-closed. Therefore, $\mathcal{IVC}([\mathcal{M}^-,\mathcal{M}^+]) - [\mathcal{M}^-,\mathcal{M}^+]$ is $\mathcal{IV}$g-closed.
(3) ⇒ (2): Let $[\mathcal{S}^-,\mathcal{S}^+] = (\mathcal{IVC}([\mathcal{M}^-,\mathcal{M}^+]) - [\mathcal{M}^-,\mathcal{M}^+])^c$. Then $[\mathcal{S}^-,\mathcal{S}^+]$ is $\mathcal{IV}$g-open and $[\mathcal{M}^-,\mathcal{M}^+] = [\mathcal{S}^-,\mathcal{S}^+] \cap \mathcal{IVC}([\mathcal{M}^-,\mathcal{M}^+])$.
(3) ⇒ (4) and (4) ⇒ (3): These follow by taking complements, since $(\mathcal{IVC}([\mathcal{M}^-,\mathcal{M}^+]) - [\mathcal{M}^-,\mathcal{M}^+])^c = [\mathcal{M}^-,\mathcal{M}^+] \cup \left(\widetilde{X} - \mathcal{IVC}([\mathcal{M}^-,\mathcal{M}^+])\right)$.

ABSTRACT

Blended learning, a pedagogical technique that mixes face-to-face teaching with online learning experiences, has grown in popularity as digital technologies are more integrated into education. While blended learning has grown in popularity in secondary school, little study has been conducted to investigate how technology acceptance, teacher-supported social contact, and learning flexibility contribute to students' long-term skill development. The current research, which is based on the Technology Acceptance Model (TAM), Social Constructivist Theory, and Sustainable Development Goal 4 (Quality Education), looks at how these elements affect the development of important twenty-first-century abilities in blended learning contexts. To analyse the associations between the research variables, a quantitative descriptive correlational survey approach was used, with data gathered from 720 secondary school students studying in mixed learning settings in Meerut District, Uttar Pradesh. Pearson correlation and regression analyses were used to investigate the correlations and predicted impacts of technology adoption, teacher-facilitated social contact, and learning flexibility on long-term skill development. The data demonstrated that all three aspects had a substantial and favourable effect on students' skill development. Technology adoption was the most significant predictor ($r = 0.821$, $p < .001$), accounting for 67.4% of the variation in sustainable skill development. Learning flexibility ($r = 0.781$, $p < .001$) accounted for 61.0% of the variation, whereas teacher-supported social contact ($r = 0.616$, $p < .001$) explained 38.0%. The findings show that students who perceive educational technologies as accessible and useful, receive meaningful teacher support, and have access to flexible learning opportunities are more likely to develop communication, collaboration, critical thinking, self-management, and technological competencies. The research suggests that technological acceptance, teacher-supported social contact, and learning flexibility all work together to promote long-term skill development in blended learning settings. By including the viewpoints of TAM,

Social Constructivist Theory, and SDG 4, this research adds to a better understanding of how blended learning may enhance future-ready skills and promote inclusive, equitable, and quality education.

Keywords: Blended Learning, Technology Acceptance, Teacher-Supported Social Interaction, Learning Flexibility, Sustainable Skill Development, SDG 4, Secondary Education.

INTRODUCTION

The rapid growth of information and communication technologies (ICTs) has led to the alteration of educational processes all over the globe. The use of digital technologies in the process of instruction has created prerequisites for the formation of the blended learning approach which is based on combining classical classroom-based instruction with online learning. Blended learning has attracted much attention recently because of the ability of this approach to provide flexible and learner-centered educational process and development of key competencies of the twenty-first century (Garrison & Kanuka, 2004; Hrastinski, 2019). In today's educational process, the emphasis has shifted from achievement in learning to the development of skills that will allow learners to adapt to changes in social, technological and professional environment. Communication, collaboration, critical thinking, self-management, technological skills are among such important skills that should be developed by learners to continue their learning process in life-long basis and be competitive in professional environment (Voogt & Roblin, 2012; UNESCO, 2021). It means that modern educational establishments are increasingly using the blended learning approach in their practice. The effectiveness of the blended learning approach depends on several interrelated aspects. Technology acceptance is one of the significant factors that influence student engagement. It entails the way learners view educational technologies in terms of their usefulness, availability, and ease of use. In the Theory of Technology Acceptance Model (TAM), students will be willing to adopt the usage of digital learning technologies when they find them to be useful and easy to use (Davis, 1989). With the evolution of educational technologies due to advancements in artificial intelligence and the development of digital learning platforms, technology acceptance is an essential factor.

Teacher-mediated social interaction is another essential element of successful blended learning. Although the use of technology has increased tremendously in the education sector, learning is still fundamentally a social activity. Social Constructivist Theory stresses that knowledge is actively constructed via interaction, collaboration, and mediation (Vygotsky, 1978). Feedback by the teacher, academic assistance, classroom communication, and collaboration are significant components of blended learning that contribute to students' development of higher order thinking and meaningful learning. Research indicates that there are benefits of teacher and student interaction in blended learning environments that increase engagement, motivation and skill development. Another benefit of blended learning is the aspect of learning flexibility, which is consistent with Sustainable Development Goal 4 (SDG 4) and its emphasis on providing all learners with inclusive, equitable and quality education (United Nations, 2015). Learning flexibility enables the learner to have access to educational materials based on his or her needs, to study at their own pace and to manage learning schedules. While some studies have examined the effects of blended learning on academic performance, technology integration, and learning engagement, the role of technology acceptance, teacher supported social interaction and learning flexibility on sustainable skill development among secondary school students has received little attention in the literature. Moreover, studies that have considered all three components (Technology Acceptance Model, Social Constructivist Theory, and SDG 4) in a single framework to analyze sustainable skill development in blended learning environments are rare in the literature. This is an especially important aspect since the students in secondary schools learn fundamental skills needed for their future success. Hence, the current research project will examine the effect of technology acceptance, teacher supported social interaction and learning flexibility on sustainable skill development among secondary school students in blended learning environments by integrating TAM, Social Constructivist Theory and SDG 4.

LITERATURE REVIEW

Technology Acceptance Model and Blended Learning

One such model that has made great influence on the understanding of why people accept or adopt technology is the Technology Acceptance Model (TAM), proposed by Davis (1989). It states that perceived usefulness and perceived ease of use are two main factors that determine people's intentions to use new technologies (Davis, 1989). These factors play an important role in determining how people will be ready to use digital learning systems within the context of their education. Increased application of blended learning models has raised the issue of technology acceptance among students and educators. Blended learning is the combination of traditional face-to-face instructions and modern technologies that allow learners to use different methods of accessing educational information (Garrison & Kanuka, 2004). A number of studies indicate that perception of educational technologies as being useful and easy to use leads to increased engagement, participation, and efficiency of learning (Al-Rahmi et al., 2022; Rasheed et al., 2020). At the same time, innovations in AI and generative AI have added more importance to TAM, since perception of usefulness, accessibility, and interactivity has become crucial for acceptance of such technologies among learners (Kasneci et al., 2023). The role of technology acceptance has increasingly been acknowledged as an essential aspect that has been influencing the learning outcomes in the twenty-first century. It has been observed that when the students make efficient use of digital technologies, it helps them develop effective communication, collaboration, problem-solving, and technical skills (Bond et al., 2021). The concept of technology acceptance in the current research includes the following aspects.

Social Constructivism Theory and Teacher-Supported Interaction

The Social Constructivism Theory, put forward by Vygotsky (1978), suggests that learning is a social phenomenon where knowledge is created through social interaction. The theory stresses the importance of the concepts of collaborative learning, discussion, scaffolding, and guided learning in cognitive development. Vygotsky (1978) says that meaningful learning takes place through social interaction when learners construct knowledge in the Zone of Proximal Development. In blended learning settings, teacher-mediated interaction continues to be an important component of teaching. While technology enables learners to have access to information, the meaningful learning process relies greatly on the quality of interaction between teachers and learners (Hrastinski, 2019). Studies suggest that teacher feedback, academic assistance, group work, and communication are some major factors that help learners in engaging with the process and achieving educational success (Martin et al., 2020). Good teacher assistance facilitates reflection about the learning process and its application to the real-world situations by identifying and correcting misunderstandings. Recent research has proved that the interactive learning environment plays a significant role in improving communication, critical thinking, collaboration, and problem-solving skills (Khalil & Ebner, 2024). These results are consistent with the Social Constructivist theory suggesting that the effectiveness of learning results can be enhanced through active participation in collaboration and supportive learning environments.

Learning Flexibility and SDG 4

Flexibility in learning is considered one of the most important features of blended learning. Flexible learning environments give learners the opportunity to gain access to education-related content in flexible time frames and also enables them to learn at their own pace. Flexibility allows customization in learning according to the needs of the individuals (Boelens et al., 2017). This aspect of learning flexibility enables learners to become autonomous, regulate their own learning process, and engage in personalized learning, all necessary for lifelong learning. Learning flexibility is highly connected with Sustainable Development Goal 4 (SDG 4) (United Nations, 2015). The fourth SDG focuses on issues of accessibility, inclusivity, and learner-centered education that allow all learners to actively engage in educational processes. Blended learning environments can help realize the goals stated above through decreasing barriers associated with time, space, and access to educational materials. According to scientific evidence, flexible learning can positively impact motivation, self-regulation, and academic perseverance of students (Broadbent & Poon, 2015; Müller & Mildenberger, 2021). When learners are capable of managing their learning processes independently, they tend to have better skills in independent learning and being ready to take further steps in both

educational and professional life. Thus, learning flexibility is one of the key aspects of educational sustainability and SDG 4.

Sustainable Skill Development

The issue of sustainable skill development has been given serious attention in current education systems because of the growing need to produce adaptable graduates that are prepared for the future. In addition to academic success, educational institutions are supposed to develop such skills among learners which help them survive in constantly changing technological and societal environment (UNESCO, 2021). Communication, cooperation, critical thinking, self-management, and technology skills are among the required abilities. Sustainable skill development is not limited by its present use and refers to the development of skills that enable the process of lifetime learning and employment. Studies prove that blended learning environment provides favorable circumstances for sustainable skill development through the use of technologies, collaborative learning and flexible instruction (Voogt & Roblin, 2012; Redecker, 2017). This type of learning promotes active participation of learners in the educational process and development of competencies which are needed in the twenty-first century. Thus, technology acceptance, teacher-supervised interaction and learning flexibility altogether play an important role in fostering sustainable skill development and making educational environments which encourage learners' engagement, autonomy, collaboration and knowledge creation. It is crucial to understand the influence of these elements on the problem being discussed.

Research Gap

While there have been numerous studies concerning the effects of technology adoption, teachers' support, learning flexibility, and educational performance separately, there is no substantial research on the joint impact of all these factors on the sustainability of skill acquisition in secondary schools within the context of blended learning. Current research mainly concentrates on educational performance, the role of technology in the educational process, or university-level education. Moreover, only a few studies combine the Technology Acceptance Model, Social Constructivist Theory, and SDG 4 into one conceptual framework in the context of skill development in secondary education. However, the fast-growing relevance of AI-assisted learning settings demands for study into the effect of technological adoption, social interaction, and learning flexibility on the sustainability of skill development.

Research Objectives

RO1: To examine the influence of technology acceptance on sustainable skill development.
RO2: To investigate the role of teacher-supported social interaction in sustainable skill development.
RO3: To examine the effect of learning flexibility on sustainable skill development.
RO4: To compare the relative predictive influence of Technology Acceptance, Teacher-Supported Social Interaction, and Learning Flexibility on Sustainable Skill Development

Research Questions

RQ1: How does technology acceptance influence sustainable skill development?
RQ2: How does teacher-supported social interaction influence sustainable skill development?
RQ3: How does learning flexibility influence sustainable skill development?
RQ4: Which blended learning dimension demonstrates the strongest predictive influence on Sustainable Skill Development?

Hypotheses

H1: Technology acceptance significantly influences sustainable skill development.
H2: Teacher-supported social interaction significantly influences sustainable skill development.
H3: Learning flexibility significantly influences sustainable skill development.
H4: Technology Acceptance, Teacher-Supported Social Interaction, and Learning Flexibility differ significantly in their predictive influence on Sustainable Skill Development.

MATERIALS AND METHODS

The methodology of research is a set of methods and techniques of collecting, analysing, and interpreting information for solving problems of research. It is a system through which the results obtained by the research can be reliable and valid. In this study, a quantitative research methodology was used to assess the impact of Technology Acceptance, Teacher-Supported Social Interaction, and Learning Flexibility on Skill Sustainability. Information was collected from secondary school learners using two questionnaires. Pearson correlation and regression were some of the statistical techniques used.

Research Design

A quantitative Correlational survey technique was utilised in the study to determine the influence of blended learning characteristics on students' skill development.

Population and Sample

This study's population consisted of secondary school pupils from Uttar Pradesh's Meerut district. The sample contained 720 respondents, consisting of 360 male and 360 female students.

Sample Size Calculation

The sample size was determined using Cochran's (1977) formula for large populations.

Formula:

$n_0 = Z^2pq / e^2$

Where:

- n_0 = Required sample size
- Z = 1.96 (95% confidence level)
- p = 0.50
- q = 0.50
- e = 0.0365 (Margin of error)

Calculation:

$n_0 = (1.96)^2 \times (0.50 \times 0.50) / (0.0365)^2$

$= (3.8416 \times 0.25) / 0.00133225$

$= 0.9604 / 0.00133225$

$= 720.88 \approx 720$ students

As a result, a sample of 720 secondary school pupils was deemed appropriate for the research. The total sample included 360 male and 360 female students.

Sampling Technique

In this research, the sampling approach used is multistage sampling. In the first phase, the secondary schools offering blended learning in Meerut District were considered. Then, in the second phase, the 24 schools were sampled through the Lottery method (simple random sampling). Finally, in the last phase, 30 students from each school were sampled using simple random sampling, giving a total sample size of 720 students.

Instrumentation

The data was collected through two structured questionnaires that were designed to capture the dimensions of blended learning and skill sustainability. In the questionnaire, the questions included those on technology acceptance, teacher-mediated social interaction, flexibility, and students' skills. The responses were given on a five-point Likert scale ranging from strongly disagree to strongly agree.

For collecting data, two structured questionnaires were used. First, the Blended Learning Instrument Scale (BLIS) questionnaire comprised 15 questions, with five items measuring technology acceptance, teacher-facilitated social

interaction, and learning flexibility, respectively. Second, the Sustainable Skill Development Scale (SDS) questionnaire comprised 25 questions, with five items measuring communication skills, collaboration skills, critical thinking, self-management, and technology proficiency, respectively. The answers to all items were taken on a five-point Likert scale.

Reliability of the Instrument

Cronbach's alpha was used to assess the research tool's reliability and the scales' internal consistency. The table below displays the reliability coefficients of the variables. Cronbach's Alpha reliability coefficients were calculated to determine the research tool's internal consistency. The reliability coefficients varied from 0.846 to 0.918, showing good to excellent internal consistency. The overall reliability coefficient of 0.893 reveals that the research tool has sufficient reliability in measuring the concepts of technology acceptance, teacher supported social interaction, learning flexibility, and sustainable skill development. The reliability coefficients of Cronbach's Alpha were all above the threshold level of 0.70 (Nunnally & Bernstein, 1994).

Validity of the Instrument

The validity of the study instrument's content was assessed via expert validation. A committee of subject matter experts in education and blended learning evaluated the questionnaire questions. Irrelevant or unclear questions were removed or modified depending on their feedback. This contributed to the validity of the conceptions of technological acceptance, social interaction under instructor leadership, learning flexibility, and sustained skill development.

Variables of the Study

Independent Variables

- Technology Acceptance (derived from Accessibility & Use of Technology)
- Teacher-Supported Social Interaction (derived from Teacher Support & Interaction)
- Learning Flexibility (same dimension)

Dependent Variable

Sustainable Skill Development

Data Analysis

The data was analysed using the Statistical Package for Social Sciences (SPSS). Descriptive statistics were employed to summarise the participants' replies. The Pearson correlation test was used to determine the relationship between variables, and the simple linear regression test was used to establish the predictive influence of each blended learning component on student skill improvement. Statistical significance was evaluated at the 0.05 level.

RESULTS

This section summarises the findings of the statistical studies undertaken to determine the impact of Technology Acceptance, Teacher-Supported Social Interaction, and Learning Flexibility on Long-Term Skill Development. The data from 720 secondary school pupils was examined using Pearson correlation and basic linear regression techniques. The results are given based on the study goals and assumptions.

Overview of Students' Perceptions of Blended Learning Dimensions

Technology Acceptance

Positive perceptions were found among the students in regards to their access to digital devices, online learning materials, and usability of the platform.

Teacher-Supported Social Interaction

Student perceptions about the significance of teacher's feedback, class interaction, communication, and academic assistance in enhancing learning efficiency have been stated.

Learning Flexibility

Students appreciated the flexibility to manage study schedules, revisit learning content, and learn at their own pace, highlighting the learner-centred nature of blended learning.

Descriptive Statistics of the Study Variables

Testing of Hypothesis

H1Technology Acceptance is significantly associated with Sustainable Skill Development.

Effect of Technology Acceptance on Sustainable Skill Development (RO1)

The Pearson correlation test was applied in order to determine the extent of association between technology acceptance and sustainable skill development. The findings show a highly positive and statistically significant association between technology acceptance and sustainable skill development ($r = 0.821$, $p<0.001$). It can be concluded that students who accept educational technologies as being useful, easily accessible and easy to use tend to exhibit higher levels of communication skills, collaborative skills, critical thinking skills, self-management skills, and technological skills. The findings confirm the predictions of the Technology Acceptance Model by Davis (1989) that learners tend to be more inclined towards using educational technologies when they believe that the technologies are helpful and easy to use.

Testing of Hypothesis H2

Teacher-Supported Social Interaction is significantly associated with Sustainable Skill Development.

The Pearson correlation analysis was used in this case in order to evaluate the association between Teacher-Supported Social Interaction and Sustainable Skill Development. The findings of the Pearson correlation analysis showed that there exists a strong positive and statistically significant association between Teacher-Supported Social Interaction and Sustainable Skill Development ($r = 0.616$, $p < .001$, $N = 720$). The presence of such a strong positive relationship implies that the students experiencing a greater amount of teacher support, prompt feedback, constructive interaction in the classroom and proper academic guidance are likely to have better skills developed in themselves. The positive relationship shows that any increase in teacher-supported social interaction leads to increased development of the communication skills, collaborative skills, critical thinking, self-management and technological skills of the students. The small value of the p-value means that the association is statistically significant. Therefore, hypothesis H2 is accepted.

Testing of Hypothesis H3

H3Learning Flexibility is significantly associated with Sustainable Skill Development.

The Pearson's Correlation Analysis was performed to find out the relationship between Learning Flexibility and Sustainable Skill Development. The results show that there is a highly positive and statistically significant relationship between Learning Flexibility and Sustainable Skill Development ($r = 0.781$, $p < .001$, $N = 720$). This implies that learners having more flexibility in accessing learning resources, arranging study schedule and pacing learning have higher levels of sustainable skill development. The high positive correlation implies that learning flexibility contributes positively to communication skills, collaboration, critical thinking, self-management skills and technological skills of secondary school learners. As the p-value is lower than 0.001 level of significance, the relationship is statistically significant and is not random in nature. Hence, Hypothesis H3 is accepted showing that Learning Flexibility is significantly related to Sustainable Skill Development.

Testing of Hypothesis H4

H4: Technology Acceptance, Teacher-Supported Social Interaction, and Learning Flexibility significantly predict Sustainable Skill Development, and their relative predictive influence differs.

Interpretation

The Model Summary of the multiple linear regression analysis is shown in Table 4.5. The multiple correlation coefficient (R = 0.844) represents the existence of a strong positive association between the combined predictor variables (Technology Acceptance, Teacher-Supported Social Interaction, and Learning Flexibility) and Sustainable Skill Development. The coefficient of determination ($R^2 = 0.713$) represents the proportion of 71.3% of the variance in Sustainable Skill Development that is jointly explained by all three predictor variables. The Adjusted R^2 value of 0.712 represents the high predictive power of the model even after considering the number of predictors used in the model.

Interpretation

As seen from the ANOVA test, there is significance in the regression analysis ($F(3,716) = 592.468$, $p < .001$), and therefore, the model shows that the joint effects of Technology Acceptance, Teacher-Supported Social Interaction, and Learning Flexibility have a significant influence on Sustainable Skill Development. To find out the cumulative effect of Technology Acceptance, Teacher-Supported Social Interaction and Learning Flexibility on Sustainable Skill Development, multiple regression analysis was performed. Multiple regression analysis was found to be significant ($F(3,716) = 592.468$, $p < .001$), accounting for 71.3% of the variability in Sustainable Skill Development ($R^2 = 0.713$). Of the three predictors, Technology Acceptance proved to be the most influential predictor ($\beta = 0.389$, $p < .001$) of Sustainable Skill Development, which means that students who view educational technology as being helpful and easily accessible are those who are able to acquire sustainable skills. The second strongest predictor was Teacher-Supported Social Interaction ($\beta = 0.279$, $p < .001$), which suggests that teacher's feedback and guidance together with effective interaction in class play an important role in developing skills of students. Learning Flexibility also proved to be a statistically significant factor in skill development ($\beta = 0.223$, $p < .001$).

Based on the standardized beta coefficients, the relative predictive influence of the three dimensions was ranked as follows:

- **Technology Acceptance ($\beta = 0.389$)** – Strongest predictor
- **Teacher-Supported Social Interaction ($\beta = 0.279$)** – Second strongest predictor
- **Learning Flexibility ($\beta = 0.223$)** – Third strongest predictor

Thus, Hypothesis H4 is accepted, which shows that Technology Acceptance, Teacher-Facilitated Social Interaction, and Learning Flexibility together predict Sustainable Skill Acquisition, where Technology Acceptance has the most significant impact on predicting this phenomenon.

DISCUSSION

From the above study results, it is evident that Technology Acceptance, Teacher-Supported Social Interaction, and Learning Flexibility are significantly related to Sustainable Skill Development among secondary school learners in the blended learning setting. According to the correlation analysis results, Technology Acceptance showed the most significant correlation with Sustainable Skill Development ($r = .821$, $p < .001$). Based on the results, it can be concluded that secondary school learners who view educational technologies as useful, readily available, and easy to operate tend to develop skills in communication, collaboration, critical thinking, self-management, and technologic competencies. These results are in line with the Technology Acceptance Model developed by Davis (1989) since according to his model, perceived usefulness and ease of use play an important role in technology acceptance. Al-Rahmi et al. (2022), Bond et al. (2021), Kasneci et al. (2023), and Rasheed et al. (2020) reached similar conclusions based on their research findings that technology acceptance increases student engagement, digital competence, and twenty-first-century skills development. The results also revealed a statistically significant positive correlation between Teacher-Supported Social Interaction and Sustainable Skill Development ($r = .616$, $p < .001$). The above-mentioned result suggests that teacher-guidance, appropriate feedback, and class interaction play an essential role in the development of skills among students. These results are consistent with the theoretical framework of Vygotsky's (1978) Social Constructivist Theory that emphasizes the significance of social interaction for knowledge acquisition. The previous studies carried out by Hrastinski (2019), Martin et al. (2020), and Khalil and Ebner (2024) have also

highlighted that teacher support and collaboration have a positive impact on communication, critical thinking, and student participation.

In addition, a significant positive correlation was established between Learning Flexibility and Sustainable Skill Development ($r = .781$, $p < .001$). Those students who could easily get hold of learning resources, organize their learning schedule, and learn at their own pace showed high levels of skill development. The results are in agreement with the learner-centred approach of Sustainable Development Goal 4 (United Nations, 2015) and are in line with the research by Boelens et al. (2017), Broadbent and Poon (2015), Müller and Mildenberger (2021), and UNESCO (2021).
Lastly, the multiple regression revealed that Technology Acceptance, Teacher-Supported Social Interaction, and Learning Flexibility collectively accounted for 71.3% of the variance in Sustainable Skill Development ($R^2 = .713$). Of the three predictors, Technology Acceptance appeared to be the best predictor ($\beta = .389$), Teacher-Supported Social Interaction ($\beta = .279$), and Learning Flexibility ($\beta = .223$). The results show that while all three constructs significantly affect Sustainable Skill Development, the acceptance and efficient use of educational technology by students has the greatest impact when other variables are taken into consideration. This result is consistent with Davis (1989), Al-Rahmi et al. (2022), Bond et al. (2021), Martin et al. (2020), and Kasneci et al. (2023), which also stressed the significance of technology acceptance in enhancing learning outcomes despite the importance of teacher support and learning flexibility.

Implications

The findings of this study have important implications for educational institutions, policymakers, teachers, curriculum developers, and researchers seeking to enhance sustainable skill development through blended learning.

Educational Implications

There is a need to improve the accessibility of technology by students as well as provide them with an environment which encourages the appropriate use of technology. Considering the fact that technology acceptance has proved to be the most significant predictor of skill formation, there is a need for educational institutions to facilitate the availability of digital infrastructure, LMSs, and other online resources.

Pedagogical Implications

Teachers have an important role to play in ensuring that learning takes place through ongoing interaction and feedback as well as academic support. From the results, it is clear that interaction between learners and teachers is an important factor in developing skills. This implies that learners should be taught through strategies that will make them interact.

Curriculum Implications

The curriculum designers must plan to create flexible learning experiences. They can do so by providing flexible learning paths, self-paced modules, digital learning material, and a variety of instructional techniques. This would foster autonomy and self-directed learning among learners. In doing so, they would develop sustainable skills for lifelong learning and employability.

Policy Implications

The paper brings out the importance of formulating policies that ensure equal access to digital learning and facilitate the adoption of blended learning approaches. Governments should provide technology infrastructure, training of teachers, and initiatives that foster digital literacy to ensure that there is reduced inequality in education and enhanced learning outcomes. Such efforts would go a long way towards meeting SDG 4 on inclusive and quality education for all.

Research Implications

Potential future research can consider expanding the framework to include more factors like digital literacy, self-efficacy, learning motivation, learning through artificial intelligence, and student resilience. Other areas where this framework can be tested for its applicability include different academic levels, different fields of study, and different geographical locations. This research study was conducted to find out the effect of Technology Acceptance, Teacher-Supported Social Interaction, and Learning Flexibility on the Sustainable Skill Development of secondary school students in blended learning settings. Based on the Technology Acceptance Model (TAM), Social Constructivist theory, and SDG 4, this research study contributes to the knowledge in a complete way in terms of how the different dimensions of blended learning impact the development of skills necessary for the twenty-first century. All three dimensions have shown a positive and significant impact on sustainable skill development. In addition, the multiple regression analysis showed that Technology Acceptance, Teacher-Supported Social Interaction, and Learning Flexibility together accounted for 71.3% of the variance of Sustainable Skill Development. Of all the three predictors, the one that was found to be the most important predictor of Sustainable Skill Development was Technology Acceptance, which underscores the need for creating learning technologies that are accessible, user-friendly and effective in the context of blended learning. Teacher-Supported Social Interaction was found to be the second most important predictor of Sustainable Skill Development, which indicates that the need for guidance from teachers, provision of feedback and social interactions play a vital role in helping the learners gain communication, collaboration and critical thinking skills. Learning Flexibility too had an important bearing on Sustainable Skill Development because it helped learners to pace themselves while learning, access learning materials easily and regulate themselves better as learners. Thus, education systems must ensure that they have strong digital infrastructure, practice interactive teaching methods, and develop an environment that allows students to participate actively and become lifelong learners. By ensuring that the use of blended learning models is in line with the concepts of Technology Acceptance Model, Social Constructivism Theory, and Sustainable Development Goal 4, the schools will be able to provide secondary school students with the necessary skills needed in the modern digital age.

Competing Interest

The author certifies that there are no conflicting interests in the publishing of this research report. The author has no financial, professional, or personal ties that might have affected the work disclosed in this research.

Consent for publications

Not applicable. The manuscript does not include any specific person's data, photographs, videos, or other personal information that requires approval for publishing.

Ethics approval and consent to participate

The work followed established research ethics criteria. Participation in the study was optional, and all individuals gave informed permission prior to data collection. The individuals were told about the research's objectives and promised that the findings of their responses would be kept secret and utilised only for academic purposes. No personal data were gathered throughout the study.

Limitations of the Study

There are various limitations of the present research, which should be kept in mind when assessing the conclusions of the study. This is because the sample consisted only of students studying at the secondary level in Meerut District, Uttar Pradesh, and this could confine the generalization of the findings to other parts of the world or other education levels. This research utilized self-reported data obtained through questionnaires; hence, there is a possibility that the respondents have provided biased responses due to social desirability. The use of the cross-sectional research design in the current research does not allow making any causal inference about the studied variables.

ACKNOWLEDGEMENTS

The authors would like to express their gratitude to the participating schools, teachers, and students for their valuable cooperation and support during the data collection process.

Competing Interests

The authors declare that they have no competing interests. There are no financial, professional, or personal relationships that could have influenced the research or the interpretation of its findings.

Consent for Publication

Not applicable. The manuscript does not contain any personally identifiable information, photographs, videos, or other materials requiring consent for publication.

Ethics Approval

The study was conducted in accordance with established research ethics principles. Participation in the study was voluntary, and informed consent was obtained from all participants prior to data collection. The participants were informed about the purpose of the study and assured that their responses would remain confidential and would be used solely for academic and research purposes. No personally identifiable information was collected.

Authors' Contributions

Shivali Kaushik contributed to the conception and design of the study, literature review, development of the research instrument, data collection, statistical analysis, interpretation of the findings, and preparation of the manuscript. Anoj Raj contributed to the supervision of the research, critical review of the manuscript, and final approval of the submitted version. Both authors read and approved the final manuscript.

Funding

The authors received no specific funding or financial support for this research from any governmental, commercial, or non-profit organization. The study was conducted as part of an independent academic research project.

ABSTRACT

Drug abuse has become a major global social and public health issue, with regional variations in its severity and features. In recent decades the issue has grown alarmingly in Jammu and Kashmir, especially in the Kashmir Valley. The current study examines the pattern and prevalence of drug abuse in Jammu and Kashmir, identifies the major substances abused, and situates the problem within the broader structural context of the region. The study adopted descriptive and analytical research approach based on gathered secondary sources including government reports, electronic databases, peer-reviewed articles, newspapers and existing studies. The collected data was evaluated by using qualitative content analysis which involved systematic reading, interpretation and synthesis of the gathered literature to reach the results. The findings indicate the sharp rise in heroin and opioids use, the increasing trend of intravenous drug consumption, and the serious health effects associated with drug abuse. The findings also showed that drug abuse in Kashmir is strongly associated with prolonged political uncertainty, unemployment, disruption of education, strained social bonds and lack of institutional support. Thus, the drug addiction in the region cannot be understood alone without considering its socio-structural circumstances, which emphasizes the necessity of comprehensive and contextually aware intermediations

Keywords: Drug Abuse, Prevalence, Structural, Pattern, Jammu and Kashmir

INTRODUCTION

The issue of drug abuse has emerged as a significant social and public health challenge globally. Currently, every region across the world grapples with the pervasive issue of drug abuse and the illicit trade of drugs. However, its extent and features vary across different regions [1]. Approximately 190 million individuals globally engage in the use of various substances [2]. In 2012, global estimates indicated that between 162 million and 324 million individuals, representing approximately 3.5 % and 7.0 % of the population aged 15-64, had used an illicit drug primarily a substance belonging to the cannabis, opioid, cocaine or amphetamine-type stimulants category at least once in the preceding year [3]. India is also trapped in the troubling cycle of drug abuse. The prevalence of drug addicts is rising consistently with each passing day. A United Nations Report indicates that there are one million registered heroin addicts in India, with unofficial estimates stating that number could be as high as five million [4]. The most commonly substances abused in India include Cannabis, heroin, and pharmaceutical drugs produced in the country [5]. The Jammu & Kashmir region especially the Kashmir Valley has experienced a significant increase in substance usage and drug addiction in recent decades. Official estimates, submitted by the Standing Committee on Social Justice and Empowerment to the Parliament of India in 2023, indicate that approximately 1.35 million individuals in Jammu & Kashmir are engage in drug use, with a significant proportion actively using opioids, cannabis, inhalants, sedatives, and other psychotropic substances [6].

Among them, opioids particularly heroin have emerged as the predominant substance of addiction in the Kashmir Valley [7]. A 2022 survey conducted by IMHANS in ten districts indicated that among 1,500 drug users, 85.3% used opioids, and 52% of them preferred injection as their method of administration. The same study estimated the prevalence of opioid dependency in the population at 2.23% [8]. Apart from the increasing prevalence of drug use, the region has seen prolonged political instability, armed conflict, human rights violation and economic turmoil. The ongoing political turmoil, curfews, unemployment, disruption in education and daily life, military presence and psychological distress have contributed to what many analysts describe as a "valley of despair" a societal context characterised by frustration, hopelessness, disrupted social connections and diminished institutional frameworks [9]. The current body of work primarily focuses on health impacts of substance abuse or factors at the individual level. There is a relatively scarce of integrated analysis connecting patterns of drug abuse and the substances abused with the broader structural context of the region, including prolonged conflict, unemployment, disrupted education, and institutional inadequacies. Besides, there has been a lack of focus on understanding drug addiction as a phenomenon embedded within social structures influenced by systematic strain rather than simply viewing it as an individual or medical issue. Thus, the study aims to bridge this gap by contextualising drug abuse in the region within its unique socio-political and structural frameworks.

Objectives

- To examine the pattern and prevalence of drug abuse in the region
- To identify the substances abused in the region
- To analyse the structural context of drug abuse in the region.

RESEARCH METHODOLOGY

The study adopted descriptive and analytical research design. The study relies exclusively on secondary data gathered from peer-reviewed research articles, government reports and statistics, national and international organisational reports, reputed newspapers and magazines, as well as electronic databases such as PubMed, Google Scholar, Research Gate were used to obtain relevant material. The collected data was analysed by using qualitative content analysis involving systematic reading, interpretation and synthesis of the collected literature to identify the pattern and prevalence of drug abuse, types of substances used and the structural context of the issue in the region.

Pattern and Prevalence of Drug Abuse in Jammu and Kashmir

The United Nations Office on Drugs and Crime reports that Jammu and Kashmir has over 60,000 registered drug users, with a 1500% rise in drug usage over the past three years [10]. In March 2023, the Ministry of Social Justice and Empowerment stated that around one million individuals in the Union territory were influenced by drug abuse, with over half of them dependent on opioids [11]. A study conducted by the Jammu and Kashmir authorities revealed that over 52,000 individuals in the Kashmir admitted to using heroin. The findings of the same study stated that, on average, a user spend around 88,000 rupees ($1,063.54; £860) monthly to maintain their drug addiction [12]. The doctors at the Institute of Mental Health and Neurosciences Srinagar (IMHANS) have noted a shift in drug consumption trends. Particularly, there is a transition from the use of medical opioids like Codeine, SP, Tramadol, and Tapentadol to the more potent and perilous illicit substances, primarily intravenous (IV) heroin [13]. Dr. Yasir Rather states that over 70% of drug users at IMHANS test positive for HCV [14[a]]. A 2023 study conducted by IMHANS indicated that the prevalence of Hepatitis C among drug addicts in Kashmir is 72 percent. The institute received 150 drug abuse cases daily. It was also revealed that more than 33 thousand syringes are being used every day for heroin injections [14[b]]. On 12 June 2023, Dr. Farooq Abdullah, President of National Conference President and Member of Parliament stated that substance abuse is a prevalent issue and a silent killer of their career to the young people of Jammu and Kashmir [15]. IMHANS reports that on an average a heroin user in Kashmir expends almost 90,000 rupees monthly [16].

Substance Abused

Records from the Drug De-addiction and Rehabilitation centre in Srinagar provide a detailed overview of substance usage patterns in the region. From February 2008 to December 2016, a total of 15294 patients were registered and diagnosed based on ICD-10 criteria. Among these patients 472 were identified as alcohol users, 1359 as Opioid users, 7860 as cannabis users, 352 as cocaine users, 1080 as benzodiazepines users, 460 as volatile substance users and 3741 as poly drug users [17]. Based on another study including 189 out-patients dealing with substance addiction issues, all of whom enrolled at the Hospital for Psychiatric Diseases in Srinagar, cannabis was the most frequently misused drug followed by heroin. Cannabis users had the longest period of drug use, however displayed the lowest prevalence of drug dependency (29.9%) and the lowest rate of polydrug abuse (6.1%). On the contrary, heroin users had the highest prevalence of drug dependency (88.8%) and the highest rate of polydrug usage (83.4%) [18]. Dr. Rather says that heroin's addictive nature markedly exceeds that of cannabis and pharmaceutical opioids. Individuals seeking to quit heroin often endure intense withdrawal symptoms including bodily discomfort, pains and restlessness [11[b]]. Demographically, drug users predominantly consist of males, often unmarried having less than high school education and a considerable percentage are unemployed or without stable livelihood [19]. Numerous studies conducted in the valley revealed that individuals mostly between the age group of 17 to 30 are primarily engaged in this issue of drug addiction [20].

Structural Context

Prolonged political conflict, violence and frequent suppressions in the Kashmir valley have adversely affected the mental health of the individuals, particularly the youth which led to rise in mental disorders such as Post traumatic stress disorder (PTSD) and depression [21, 22]. These circumstances have profoundly disrupted the social structure of Kashmir [23]. Young individuals in this milieu encounter systemic barriers to legitimate accomplishments: disrupted schooling, unemployment or underemployment, absence of solid economic opportunities, shattered familial relationships and widespread uncertainty. This structural strain heightens the probability of deviant adaptations among which drug use emerges as an accessible but perilous coping mechanism. Numerous studies have revealed that drug use problems are more common in conflict-ridden areas [24, 25]. According to Nadeem et al., (2009), rising economic stress and shifting cultural norms are contributing to the rise in drug abuse. The study also revealed how the pressures and strains of contemporary life are a result of industrialization, urbanization and migration [26]. Social variables including peer pressure, familial conflict, a lack of social ties and unemployment were revealed to have a major influence on the beginning of drug use in a study among 150 teenagers admitted to de-addiction centres across three districts [27]. Notably, a large number of respondents were aware of the negative effects of drug use yet felt

unable to quit, highlighting the fact that addiction is more than just ignorance and is closely linked to psychological distress and social isolation [28].

Also, the institutional interventions such as de-addiction centres, rehabilitation services, awareness campaigns seem inadequate, little known or socially stigmatized. According to one study just 8% of participants knew that there was a de-addiction service in Srinagar, and more than 90% of respondents lacks knowledge about de-addiction procedures [29]. This institutional neglect intensifies the isolation of drug abusers, diminishes their access to treatment and increases their dependency on informal drug networks. These conditions are distinctive features of socially disorganized societies where social control is weak and illegitimate institutions thrive. Thus, the structural setting in Kashmir demonstrates a strong picture of Merton's Strain Theory, which explains deviant behaviour as a reaction to structurally induced dissatisfaction resulting from choked access to lawful means of goal fulfilment [30]. Such choked legal opportunities such as unemployment, weaker social relationships brought on by familial instability, conflict, social fragmentation, lack of institutional support, uncertainty in the conflicted region, all backing to deviant adaptation in the form of drug addiction.

DISCUSSION

The findings of the study indicates that drug abuse in Jammu and Kashmir has reached to concerning levels, especially among the youth. Several estimates indicate a significant rise in the numbers of drug addicts in the last ten years, with opioids particularly heroin becoming the most prevalent substance of misuse. The transition from medicinal opioids and cannabis to more potent substances like intravenous heroin indicates a concerning evolution in drug use behaviours. This shift has notably heightened health risks marked by a substantial prevalence of Hepatitis C among drug users and a growing reliance on injectable substances. The results from the data of de-addiction centres show that cannabis continues to be widely used, while heroin users demonstrate the highest levels of dependence and poly-drug use. The demographic profile of drug users is primarily characterised by youth, with a significant representation of males who are unmarried, unemployed and possess lower educational attainment, highlighting the susceptibility of young individuals within the current socio-economic framework. Even with a clear understanding of the detrimental consequences of drug use, many users indicate a struggle to stop, highlighting the compulsive nature of addiction and its profound connections to psychological turmoil and social isolation. The structural context of Kashmir significantly influences these patterns. The ongoing political instability, coupled with frequent curfews and movement restrictions, has led to significant disruptions in education and a scarcity of employment opportunities, ultimately undermining social institutions and legitimate pathways for social mobility. Young individuals encountering limited opportunities, uncertainty, and frustration are more inclined to turn to maladaptive coping strategies, including substance use. Moreover, insufficient institutional interventions, a deficit of awareness regarding de-addiction services, and the presence of social prejudice continue to stigmatise drug addicts and restrict their access to treatment. In this context, drug abuse in Kashmir illustrates a wider issue of social disorganisation and structural strain, rather than merely an individual deficiency.

Suggestions

- Enhancing and broadening de-addiction and rehabilitation services to guarantee greater accessibility and awareness within the community.
- Improving awareness initiatives to diminish stigma linked to addiction and encourage early intervention.
- Tackling fundamental structural challenges like unemployment, educational disruption, and social alienation, especially among young people.
- Enhancing collaboration among institutional agencies to guarantee efficient outreach, treatment, and rehabilitation services.
- Encouraging the establishment of community-driven support systems to restore social connections and offer ongoing assistance for those in the process of overcoming addiction.

CONCLUSION

The issue of drug abuse in Jammu and Kashmir presents a multifaceted social challenge, stemming from both personal susceptibility and broader systemic factors. The escalating rates of opioid and heroin consumption, the growing dependence on injectable substances, and the related health implications indicate the gravity of the situation. The results indicate that substance dependence in the area is significantly linked to extended periods of conflict, economic turmoil, high unemployment rates, interrupted educational opportunities, and diminished social and institutional support frameworks. To comprehend drug abuse in Kashmir, it is essential to move beyond a limited medical or moral perspective and acknowledge it as a consequence of wider socio-structural limitations that influence individual actions.

ABSTRACT

Agriculture is being transfigured by the combination of Internet of Things (IoT) technologies and machine learning (ML) techniques, which offer intelligent solutions for accurate and sustainable farming. This review examines the integration of IoT and ML in precision farming. It draws attention to how they can work together to increase crop productivity and enhance resource utilization. This paper discusses various applications, including soil monitoring, yield prediction, crop disease detection, smart irrigation, and crop recommendations. It uses supervised, unsupervised, and deep learning models made for agricultural data to analyse various IoT structures, sensor technologies, and communication techniques. Significant obstacles are highlighted in this review, including high implementation costs, connectivity issues, and data privacy concerns. This research paper combines information from industry reports and peer-reviewed studies from 2009 to 2026.

Keywords: Smart Farming, Internet of Things, Machine Learning, Precision Agriculture, IoT Sensors.

INTRODUCTION

The Internet of Things (IoT) has emerged as a game-changing technology in the agricultural sector, enabling real-time monitoring and automation of farm processes using interconnected sensors, devices, and communication networks[1]. Depending on the operational requirements, various sensor types are utilized in the smart agriculture sector. Sensors can be divided into various typical categories, such as (1) location sensors, (2) optical sensors, (3) mechanical sensors, (4) airflow sensors and (5) electrochemical sensors. These sensors are used to collect information such as air temperature, soil temperature, air humidity, soil moisture, leaf moisture, precipitation, wind speed, wind

direction, solar radiation, and barometric pressure [2].IoT-based smart agricultural systems have been used to monitor soil moisture, temperature, humidity, and crop health, significantly reducing manual labor and resource wastages[3]. These advancements have the potential to shift agricultural practices from reactive to proactive management. Parallel to the rise of the IoT, Machine Learning (ML) has demonstrated exceptional capabilities in data-driven decision-making, pattern recognition, and predictive modeling. ML algorithms such as Support Vector Machines (SVM), Decision Trees, Convolutional Neural Networks (CNN), and Long Short-Term Memory (LSTM) Models are widely applied in agriculture for tasks such as disease detection, yield prediction, weather forecasting, and automated irrigation [4][5]. The global agricultural sector is undergoing a profound transformation driven by two converging disruptions: the Internet of Things (IoT) and Machine Learning (ML). Traditional farming methods face limitations in meeting the growing food demand, climate change, and resource scarcity. Precision Agriculture (PA) has emerged as a solution by enabling data-driven, site specific interventions that optimize input use and sustainability [6]. The integration of Internet of Things and Machine Learning enables precision operations that are adaptive and data-driven, helping farmers make informed decisions to improve productivity and sustainability of their farms. Despite the apparent advantages, there are still obstacles to the broad use of IoT-ML systems in agriculture, including high deployment costs, poor Internet access in rural areas, problems with data standardization, and a lack of technical knowledge among farmers [7]. In order to create robust and scalable smart agriculture platforms, it is imperative to evaluate current solutions, pinpoint any gaps, and suggest future research avenues. This study examines previous research on sensor based architectures, machine learning applications, major obstacles, and upcoming developments in IoT-enabled smart farming.

RELATED REVIEW

In agriculture, the combination of machine learning (ML) and the internet of things (IoT) have created new opportunities to address issues of productivity, environmental sustainability, and food security. This section establishes the motivation for integrating IOT and ML in modern agriculture system. Artificial intelligence models deploy advanced computational methods to evaluate soil nutrient availability and crop demands, delivering exact specifications for fertilizer application[8]. Precision Agriculture (PA), which focuses on using technology driven, data informed decision making at the micro level to optimize agricultural inputs and maximize outputs, is one of the key areas benefiting from this integration. There are Four concepts are examined in this literature review: (i) concepts and applications of precision agriculture, (ii) sensor technologies and Internet of Things architectures, (iii) machine learning techniques for agricultural data and (iv) comparative analysis of previous research.

Precision Agriculture: Concepts and Applications:

Precision Agriculture (PA) is a way of managing that collects, processes, and analyzes data about time, space, and people to help make decisions about growing crops [1][2]. It aims to improve the management of crop farming at the field level by monitoring on how physical and chemical parameters of the soil change and controlling inputs like water, fertilizer, and pesticides exactly where and when they are needed [3].Global Navigation Satellite Systems (GNSS), remote sensing, and decision support systems are used by Precision Agriculture (PA) systems to monitoring on crop growth, manage irrigation, seeding, and spraying with sub-meter accuracy [9]. Using variable rate technology (VRT), unmanned aerial vehicles (UAVs), and yield monitors makes resource use much more efficient [10]. IoT and ML have made Precision Agriculture (PA) even better by letting farmers monitoring on things in real time, use predictive analytics, and control their operations on their own [11]. Field studies conducted in the EU, Australia, and India have shown that precision strategies can save up to 30% in water usage and fertilizer and increase yields by 25% [12]. According to studies, Precise Farming is achieved by integrating IoT-sensed data with machine learning algorithms.

Sensor Technologies and IoT Architectures:

Computing power, affordability, storage, mobility, dependability, Energy efficiency and robustness are the key features of IoT devices for Precision agriculture [13]. IoT frameworks in agriculture have a layered architecture

(Fig.1) that includes perception, network, middleware, and application layers [1]. Sensor nodes are devices that collect information like the soil's pH, moisture level, nutrient level, temperature, air humidity, and rainfall [3][14]. Sensor nodes transmit the collected data to edge or cloud-based platforms using communication technologies like LoRa, NB-IoT, Wi-Fi, or Zigbee [15]. New biodegradable nanosensors enhance sustainability and enable early detection of ions such as nitrates, heavy metals, and plant pathogens at an early stage [16].For software, FIWARE, ThingSpeak, and AWS IoT Core are some of the platforms that are used to take in and control data [17]. The integration of edge computing with microcontrollers such as Raspberry Pi and NVIDIA Jetson, allows local inference to reduce latency and energy consumption [18].

Machine Learning Methods for Agricultural Data:

Predictive algorithms can utilize historical regional yield data to identify past crop performance trends. By capturing these variations, the models forecast future crop suitability and productivity for specific geographic areas [19]. Machine learning is a key part of turning raw sensor and image data into useful information. For yield prediction, weed detection, and soil management, supervised learning algorithms like Support Vector Machines (SVM), Random Forests (RF), and Gradient Boosting are used for accurate predictions [20][21]. K-means and other unsupervised clustering methods help image segmentation pixel soil plant segmentation fields based on the characteristics of the soil or crop [22]. Deep learning models, especially CNNs and RNNs (LSTM), are widely used for tasks such as crop disease detection, plant species identification and classifying remote sensing images [23][24]. High-accuracy modeling is possible with hybrid systems that combine sensor streams, drone images, and weather data. [25].

Integration of ML and IoT For Precision Agriculture:

Artificial Intelligence and Internet of things applications in agriculture have highly raised the productivity of the agriculture and operational efficiency. Precision agriculture is made possible by these technologies, which maximize the utilization of resources and increase the crop yields [26]. Current research emphasizes that real-time monitoring of environmental and soil parameters, including pH value, temperature, humidity, and soil moisture are made possible by the integration of IoT devices with machine learning models. This improves crop productivity and resource efficiency by facilitating prompt decisions about fertilization, irrigation, and crop protection [27]. This allows for the forecasting of weather patterns, crop recommendations, soil analysis, and the determination of the necessary amounts of pesticides and fertilizers. In precision agriculture systems, this predictive ability aids farmers in taking proactive measures that lower losses and enhance yield results [28].

Comparative Analsis of Existing Studies:

This section offers a comparative analysis of previous research concentrating on the integration of machine learning and sensor technologies for precision farming in order to give a clear picture of the state of IoT-enabled smart agriculture today. The transition from conventional, manual farming methods to more data-driven, automated, and predictive agricultural practice are the definite trends.

Comparative Table of Selected Studies:

This analysis identifies gaps and common trends in the literature while highlighting the diversity of research efforts. Important trends and strategic directions in the use of IoT and machine learning for precision agriculture are revealed by the synthesis of previous research. Important factors like sensor, crop type, communication protocols, data sources, machine learning techniques, and application outcomes are compared in **Table1**.

Key Comparative Insights:

Diverse Crop Coverage and Sensor Integration:

The reviewed studies cover a wide range of crops, including Gram, tomato, maize, grapes and tea, demonstrating the adaptability of IoT-based disease prediction systems across different regions. Sensor selection is highly crop-specific, with motion, optical, gas, NPK, RGB Color Sensor, temperature, humidity, and even sound sensors used to capture relevant plant health indicators [29] [31].

Communication protocols vary according to deployment scale and complexity:
Wireless sensor networks (WSN) [29], and ZigBee [33] are used in medium scale deployments for energy efficient and short range communications. Wi-Fi supports real-time, high bandwidth data transmission suitable for dense sensor networks, but may be problematic in rural or remote settings [29][33]. SDI-12 is adopted for environmental sensors, showing preference in agricultural and vineyard applications [30]. I2C and GPIO suggest localized, small scale setups with simple hardware interfaces [34].

Machine Learning Algorithm Selection Based on Data Nature and Application:
Classical Machine Learning models such as SVM , Decision Trees, and Random Forests perform reliably for image and sensor-based disease classification tasks [29] [30].Time-series or sequential models, such as Hidden Markov Models (HMMs) , and PELT are suitable for detecting disease patterns over time [32][33]. Regression based models, such as Multiple Linear Regression (MLR) are used where the relationship between multiple environmental variables and disease probability is being analyzed [34]. Bayesian optimization with KNN represents a hybrid approach to hyperparameter tuning and improving accuracy [31].

Performance accuracy and disease detection effectiveness:
Studies in **Table 1** outlines high prediction accuracy, with values ranging from 90.9% to 98%, indicating that IoT-ML integration provides strong prediction capabilities. The highest accuracy (98%) is achieved using the Random Forest algorithm in Grapevine disease detection [30], highlighting the potential of ensemble models in complex biological datasets. Some models also exhibit early detection capability (for example, PELT [32] detects symptoms 4 days after vaccination), which is important for timely intervention. This early detection capability is vital for timely intervention and crop protection.

System complexity and scalability:
Solutions involving cloud based infrastructure and Wi-Fi support real-time monitoring, but may require stable Internet connectivity, creating limitations in field deployment [31]. Simple microcontroller setups are cost-effective and easy to deploy, but may lack scalability for larger farms [34].This comparative analysis serves as a reference foundation for identifying effective configurations and recognizing where further research is needed, especially in under represented crops, energy efficient deployments, and real world system validation.

DISCUSSION

There is a great deal of variation in sensor configurations, communication protocols, and machine learning (ML) algorithms that are suited to different agricultural domains when comparing different IoT enabled crop disease prediction systems. The crop specific customization of sensors is a noteworthy observation. For example, [29] used optical and motion sensors for chickpea crops, while [30] used advanced environmental and sap flow sensors for grapevines, and [32] used RGB, NPK, and gas sensors for tomato and maize crops [33]. This highlights the importance of domain knowledge in selecting appropriate sensor configurations. Studies employ a variety of protocols in terms of communication technologies that are appropriate for operational scale and environmental constraints. Wi-Fi [31], [32] allows real-time data transmission with wide bandwidth, but with power and connectivity limitations. Wireless sensor networks (WSNs) and ZigBee [29][33] offer low-power, short-range communications that are perfect for field-scale deployments. Vineyard applications successfully employ the SDI-12 protocol [30], demonstrating its applicability for agri-environmental sensors with low data rates. However, simpler systems that make use of I2C and GPIO interfaces [34] recommend prototype-scale or localized implementations, particularly in greenhouse or research settings. Prediction requirements and the nature of data significantly influence the choice of ML models. Classical models such as Support Vector Machines (SVM) [29], Decision Trees (DT), and Random Forests (RF) [30] achieve high classification accuracy, with RF providing up to 98% accuracy, underscoring its effectiveness in handling complex, multidimensional agricultural datasets. Sequential and time-series models such as PELT[32] and Hidden Markov Models (HMM) [33], offer advantages in modeling disease progression over time,

enabling earlier intervention. Regression-based approaches, such as Multiple Linear Regression (MLR) are suitable for analyzing the correlation between environmental parameters and disease occurrence [34].

Overall prediction accuracy across studies ranges from 90.9% to 98%, demonstrating the efficacy of combining IoT infrastructure with machine learning techniques **(Fig.2)** in smart agriculture. Notably, the early detection capability achieved in maize crop disease prediction using PELT is one of the most crucial elements of proactive disease management [32]. However, factors like power consumption, communication dependability, and the ease of sensor integration in diverse agricultural contexts are critical to the scalability and viability of these systems. In conclusion, more research is required to fully address system integration, energy constraints, data limitations, and practical usability in order to make smart farming scalable and sustainable, even though IoT and ML have shown great promise in improving agricultural productivity, resource efficiency, and environmental sustainability.

Research Challenges and Limitations

Despite their promising potential, a number of practical and technological challenges continue to impede the widespread adoption of IoT and machine learning in smart agriculture. A significant bottleneck in smart farming arises from the lack of clear data sovereignty of generated by precision agricultural systems [35]. Another primary obstacles is the high cost of installing and maintaining state-of-the-art sensors, communication modules, and edge computing infrastructure, particularly in rural and economically constrained regions [36][37]. Additionally, data silos, heterogeneity, and a lack of interoperability among different hardware devices and software platforms make it more difficult to integrate data across multiple systems [7]. The scarcity of high-quality labeled datasets is another significant obstacle that prevents machine learning models from being trained and performing well [38]. Large-scale annotated data collection in agricultural settings is labor-intensive and time-consuming, especially for tasks involving crop classification and disease diagnosis [39]. Moreover, the extensive use of cloud-based platforms for data storage and remote monitoring has made privacy and cybersecurity issues more pertinent [40].

Due to concerns about possible abuse or illegal access, many farmers are still reluctant to use digital tools that gather private field data. On the other hand, several enablers and positive trends are accelerating the adoption of IoT-ML solutions in smart farming. The declining cost of sensors and the increasing affordability of LPWAN (Low Power Wide Area Network) communication protocols such as LoRa and NB-IoT have made it more feasible to implement large-scale monitoring systems even in low-income regions [41]. Reliability and low energy consumption have been further improved by the emergence of open-source IoT frameworks like FIWARE and Thing Speak as well as low power edge AI platforms like NVIDIA Jetson and Raspberry Pi [18]. Simultaneously, numerous government programs and policies, such as the European Union's Common Agricultural Policy (CAP) and India's eNAM project, are offering financial assistance, incentives, and regulatory support for the digital transformation of agriculture [42][43]. Through engineered innovations in precision agriculture, collaborative research programs such as The IoT4Ag ERC seek to bring together interdisciplinary expertise in order to achieve food, water, and energy security [44]. When combined, these enablers (Fig. 3) provide a favourable setting for removing current obstacles and expanding smart agricultural practices around the world.

Future Research Directions

Although significant progress has been made in integrating IoT and machine learning for precision agriculture (PA), many important research avenues are still open for exploration and development. In Future focus on the implementation of explainable AI techniques, hybrid ML models and block chain applied data sharing by securable for scalable and the sustainable precision agriculture solutions[45] and subsequent investigations should prioritize extended real-world evaluations, cross-regional model adaptation, and multidisciplinary frameworks that combine socioeconomic impact analysis with technical ML performance metrics [46].One promising direction is the use of reinforcement learning to create dynamic and real-time virtual replicas of farms. These digital models can simulate various agronomic scenarios and provide actionable feedback to optimize fertilization and irrigation in a continuous adaptive manner [47]. Another important area is the advancement of sensor fusion and multimodal learning, where data from different sources, such as UAV imagery, soil sensors, weather stations and satellite data, can be combined

to provide a holistic understanding of field conditions. Their application in smart farming can democratize access to AI tools while preserving data ownership [48].

Another emerging challenge is the development of robust security architectures to detect and prevent data tampering, cyber threats, and unauthorized access to data. Technologies such as secure firmware updates, block chain integration and anomaly detection algorithms will play a key role in securing smart farm infrastructure [40]. Federated and transfer learning have emerged as promising strategies to address the scarcity of labeled agricultural datasets and privacy concerns. These approaches allow collaborative model training across multiple farms without sharing raw data, ensuring both data security and personalization [49]. By integrating multiple data modalities, machine learning models can achieve robustness and higher prediction accuracy, especially in heterogeneous field conditions. With the development of edge computing, research on ultralow-power AI hardware and edge-based inference has become essential. This can enable real-time processing and decision making directly on the farm, conserving bandwidth, reducing dependence on cloud services, and improving system responsiveness [50]. In this context, the development of energy-efficient deep learning architectures and neuromorphic chips represents a promising area of investigation. Addressing these multidisciplinary challenges will help to realize the full potential of IoT-ML enabled precision agriculture can become safe, sustainable, and globally scalable.

CONCLUSION

Precision agriculture has entered a transformative phase as a result of the convergence of machine learning (ML) and the Internet of Things (IoT), which has improved decision-making, productivity, and sustainability. The developments in IoT architectures, sensor technologies, and machine learning techniques are examined in this thorough review along with their combined uses in the field of smart farming. We assessed the role of machine learning (ML) in predictive analytics for tasks like disease detection, irrigation management, yield forecasting, and soil health assessment, as well as the potential of IoT systems to enable real-time monitoring, automation, and data acquisition. Notwithstanding these developments, there are still with challenges such as limited rural connectivity, a lack of standardization, data restrictions, and worries about scalability and cost-effectiveness. Our study identifies important research gaps and suggests future paths, including the use of edge AI, interpretable machine learning models, federated learning, and sustainable IoT design frameworks. Accelerating inclusive and scalable implementation requires a multidisciplinary approach that includes data science, embedded systems, agricultural science, and policymaking. In conclusion, the current research lays a strong foundation for future innovations, even though ML and IoT applications in agriculture are still evolving and hold immense potential for the future of sustainable agriculture. The industry can advance toward a data-driven, effective, and resilient agricultural ecosystem that is in line with international sustainability and food security objectives by tackling the issues that have been identified and following the suggested paths with strategic innovation and policy suport, IOT and ML can revolutionize the global agriculture landscape.

ABSTRACT

The domain of brain and mental health research has witnessed substantial progress, driven by advancements in machine learning (ML), deep learning (DL), and artificial intelligence (AI). These data-driven approaches provide promising solutions for improving mental health care by allowing more accurate and personalized detection, diagnosis, and treatment of depression. This survey explores how AI supports depression detection, with advanced procedures using MRI images aiding in numerous stages of the treatment process. AI-powered systems enable early detection of individuals at risk, improving treatment strategies and solving the heterogeneity within depression diagnoses utilizing unsupervised learning. Different types of MRI images utilized for depression detection are classified and briefly discussed. The methods utilized in each existing depression detection techniques is discussed along with their advantages and limitations. This survey aid the researchers to gain in-depth knowledge on depression detection using MRI images through the identified research gaps.

Keywords: Depression Detection, MRI Image, Machine Learning, Deep Learning Techniques

INTRODUCTION

Depression detection

Mental health is a vital aspect of human well-being, impacting work engagement, life satisfaction, and emotional stability. Depression is a common mental disorder that significantly harms daily life, by affecting sleep patterns, cognitive function, interpersonal relationships, and work productivity. Given the growing incidence of depression,

particularly among students globally, there is a growing requirement for effective detection and diagnosis methods. Conventional diagnostic approaches depend on clinical assessments and self-report scales like the Beck Depression Inventory (BDI-II). However, these approaches are mostly subjective and susceptible to biases. This has led to the examination of advanced neuroimaging methods, mainly Magnetic resonance imaging (MRI)-based depression detection, which aims to offer an objective and precise diagnosis using brain structure and function analysis [1].

Need for automatic depression detection

Depression detection is difficult because of its high recurrence rate, complex symptoms, and inconsistency in individual responses to treatment. Conventional diagnostic approaches, including self-report questionnaires and psychiatric interviews, have several restrictions. Patients may underreport or misunderstand their symptoms, resulting in misdiagnosis. In contrast to other medical conditions, depression does not have widely accepted neurological biomarkers. Clinical interviews necessitate substantial time and expertise, postponing early intervention. Diverse clinicians may interpret symptoms in a different way, leading to unpredictable diagnoses. To tackle these challenges, researchers have moved to automatic depression detection using machine learning (ML) and neuroimaging methods. MLs can analyse large datasets of brain MRI images for identifying patterns associated with depression [2]. MRI-based analysis lessens subjectivity and offers measurable physiological indicators. Advanced algorithms can identify subtle variations in brain structure and function that may not be noticeable to the human eye. ML systems can analyse several images within seconds, supporting clinicians in decision-making. Automated systems can recognize early signs of depression before symptoms worsen, allowing timely intervention.

Depression detection from MRI images

MRI is one of the most efficient neuroimaging methods for studying depression. MRI offers high-resolution images of the brain that can be analysed for identifying structural and functional abnormalities related to Major Depressive Disorder (MDD). Neuroimaging studies have recognized numerous brain regions that show abnormalities in depression patients. In hippocampus region, reduced volume is related to memory impairments and emotional regulation problems [3]. In Dorsolateral Prefrontal Cortex (DLPFC) region, structural and functional variations influence mood regulation and decision-making. In Anterior Cingulate Cortex (ACC) area, abnormal connectivity is associated with impaired emotional processing. Changes in Posterior Cingulate Cortex (PCC), contribute to self-referential thinking and rumination. ML models process MRI images as three-dimensional objects, which is made up of voxels, each indicating a numerical measurement of structure or activity of the brain. MRI datasets have large amounts of data, necessitating substantial computational resources. Medical image datasets are often inadequate, making it hard to train deep learning (DL) models efficiently [4]. The number of depressed patients is mostly smaller when compared with healthy controls, causing biased predictions. Differences in brain structure caused by factors like gender, age, and genetics increase complexity to the analysis. In spite of these challenges, researchers are developing robust ML frameworks for extracting meaningful features from MRI data and improving depression detection accuracy [5].

Types of Depression detection (sMRI vs fMRI)

MRI-based depression detection is typically categorized into two types. Structural MRI offers high-resolution images of brain anatomy, allowing researchers to study morphological variations in brain regions related to depression. Studies have claimed that depression patients often have less hippocampal volume. Variations in white matter integrity can specify disrupted neural pathways in depression patients. It aids in understanding how depression modifies brain structure over time [6]. Functional MRI measures brain activity over time by detecting variations in blood oxygenation levels. It aids researchers to understand functional connectivity between diverse brain regions. Depression is linked to disrupted communication between brain networks, like the Salience Network (SN) and Default Mode Network (DMN). fMRI will track brain responses for happy or sad stimuli, offering understandings into emotional processing in depression patients. It is beneficial for real-time analysis and aids in analysing the dynamic interactions among different brain regions [7].

Issues

Depression detection from MRI images using ML encounters numerous challenges that affect its effectiveness and widespread acceptance. One of the primary problems is the high dimensionality of MRI data that has thousands of voxels, requiring more computational resources for processing and analysis. Additionally, small sample sizes in medical imaging datasets make it difficult to train deep learning models effectively, leading to potential overfitting and poor generalization. Another significant problem is class imbalance in which the number of depressed patients is less when compared to the number of healthy controls, causing ML models to favour the majority class and misclassify depressive cases [8]. Moreover, inter-subject variability, like differences in brain structures because of age, gender, genetics, and environmental factors, increases complexity to model training. Hence, it is difficult to develop universally accurate detection systems. Inconsistency in MRI scanners and imaging protocols across diverse medical institutions also impacts image consistency, minimizing model robustness. Moreover, the absence of widely accepted neurological biomarkers for depression indicates that ML models must depend on feature extraction techniques that may not always capture the most related information for diagnosis. Lastly, ethical and privacy concerns related to patient data usage and regulatory compliance further obscure the implementation of ML-based depression detection systems in clinical practice. Overcoming these challenges necessitates larger, well-balanced datasets, enhanced feature selection techniques, and standardized imaging protocols for enhancing model accuracy and reliability [9].

Existing Survey on Depression detection

The existing surveys on depression detection is given below. Squires et al. [11] explored the role of artificial intelligence (AI) in precision psychiatry, emphasizing its utilization across all stages of the treatment cycle. Innovative algorithms aid in recognizing individuals with mental health conditions, allowing personalized treatment for those most probable to benefit. Moreover, unsupervised learning techniques are restructuring conventional diagnostic categories by considering the heterogeneity within depression diagnoses. AI further enables a change toward evidence-based treatment prescriptions, moving beyond traditional methods depending on group averages. Chen et al. [12] performed a meta-analysis assessing the diagnostic accuracy of ML applied to resting-state fMRI data for MDD. Related studies were recovered from English databases, and their methodological quality was evaluated through the QUADAS-2 tool. A random-effects meta-analysis was executed for examining diagnostic performance using sensitivity, specificity, diagnostic odds ratio (DOR), and area under the curve (AUC). The sources of heterogeneity are explored by regression and subgroup analyses, with results representing high accuracy for ML-based automatic MDD diagnosis. Pilmeyer et al. [13] discussed challenges in recognizing consistent functional imaging biomarkers for depression and potential solutions. Progressive imaging techniques, including multiband and multi-echo imaging, along with neural network-based cleaning methods, can improve signal quality in frontal and limbic brain regions. Complete analyses integrating biological depression subtypes and dynamic functional features may enhance diagnostic precision and treatment outcome predictions, solving the heterogeneity of MDD. Developments in functional MRI imaging methods, processing, and analysis could eventually improve biomarker research and aid in more effective treatment approaches for MDD.

Survey of Depression Detection From MRI Images

Figure 1 shows the taxonomy of existing Depression Detection From MRI Images. The existing depression detection methods from sMRI and fMRI images are given below

Depression detection from sMRI Images

3D-DenseNet [14] is a voxel-based DL framework that uses a densely connected convolutional neural network. It is introduced for capturing distinct structural features. Moreover, ADNI-Transfer is a specialized transfer learning approach that is integrated with 3D-DenseNet for enhancing classification performance. Experimental assessments on neuro imaging data show substantial structural differences in brain regions, including the temporal and frontal gyri between individuals with MDD and healthy controls. The proposed DL model efficiently extracts these variations, attaining strong classification results, whereas the transfer learning method further enhances accuracy,

representing the feasibility of this approach for MDD diagnosis. The application of augmentation, feature extraction, and classification is explored in [15] for MDD detection using sMRI data. They extract representative slices with high entropy values from each 3D scan, minimizing the classification task to overcome 2D problem. Data augmentation techniques, such as rotation and duplication, are applied for balancing the dataset. DL models, such as convolutional neural networks and pre-trained architectures, are utilized for automated feature extraction, with and without fine-tuning. Comparative analysis through support vector machines (SVM) with diverse kernels shows that raw features offer strong classification performance, whereas fine-tuned pre-trained models, mainly VGG16, produce superior results with less training time.

3D FRN-ResNet [16] is an automated framework that is proposed to improve MDD identification utilizing sMRI data. A 3D-ResNet architecture is utilized for extracting and reconstructing feature representations while preserving spatial and locational details. The framework improves classification efficiency and accuracy by addressing feature reconstruction in a closed-form solution. Estimations on a neuroimaging dataset of MDD patients prove that the model surpasses conventional methods, attaining high recall, precision, and F1 scores. These findings validate the efficiency of this approach in recognizing MDD through DL-based analysis of brain structures. A study [17] is performed for replicating prior classification results in a well-featured community-based cohort of MDD patients identified through clinical interviews. Several predictive classification analyses are accomplished using features associated with brain morphology and white matter integrity. Several classifiers, such as SVM, penalized decision trees and logistic regression, are tested with and without feature selection and optimization. The classification models are then validated on large independent dataset with self-reported depression cases. The highest accuracy is attained through a decision tree classifier with cortical surface area features, emphasizing key brain regions included in MDD classification. These findings support the possibility of neuroimaging biomarkers for automated MDD detection.

Kipli et al. [18] explored the use of ML algorithms to automatically identify key data attributes related to depression detection. Several ML techniques are examined to classify depression based on features extracted from sMRI data. These features comprise volumetric measurements from diverse brain regions, including grey matter, white matter, and the hippocampus. Redundant attributes are filtered out to enhance classification accuracy, using multiple selection methods combined with search algorithms. The classification approach implemented proves enhanced accuracy when compared with several existing sMRI-based depression detection models. The potential of DL is explored in [19] in analysing structural neuroimaging data for enhanced classification and diagnostic accuracy. 3D whole-brain structures were extracted using conventional T1-weighted MRI scans and standard post-processing techniques. They developed, optimized, and evaluated a DL model across multiple datasets with MRI scans of schizophrenia patients. The proposed model surpassed a benchmark model trained on identical sMRI data using a 3D convolutional neural network architecture. The analysis emphasised subcortical brain regions and ventricles as the most prognostic features, strengthening their vital role in emotional and cognitive functions. These findings support the relationship between schizophrenia and structural brain alterations, representing the potential of DL for improving diagnosis and recognizing neuroimaging biomarkers.

Depression detection from rs-fMRI Images

Li et al. [20] investigated brain activity differences in individuals with and without anxiety in MDD using rs-fMRI. The analysis concentrated on particular brain regions, investigating discrepancies in signal intensity and regional homogeneity amongst diverse groups. Findings recommend that individuals with anxiety and MDD show lower signal intensity in key brain areas, mainly in women, emphasizing potential biomarkers for a severe MDD phenotype. These results help in understanding gender-based neural differences in depression with anxiety. Galioulline et al. [21] explored the utilization of functional connectivity and generative models for predicting future depressive episodes in individuals are not diagnosed with depression. Various ML techniques were tested for predictive accuracy using a large dataset of resting-state fMRI scans. Results show that integrating regression-based dynamic causal modelling with a support vector machine produced the most consistent predictions. However,

predictions depending on functional connectivity alone executed only slightly worse, recommending that combining multiple data modalities may improve clinical utility. Wang et al. [22] proposed a novel approach for improving depression classification utilizing fMRI data by creating functional brain networks (FBNs) with a sparse low-rank model. This method preserves vital network structures while removing weaker connections and is assessed through multiple graph-based features. The classification model proves superior accuracy when compared with conventional methods, efficiently distinguishing between healthy individuals and patients with depression. Moreover, the study recognises key brain regions contributing to classification, offering insights into the neurological basis of depression.

Zhou et al. [23] examined the relationship between anxiety and brain structure/function in individuals with MDD. Neuroimaging data, such as resting-state and structural functional scans, were analysed for comparing anxious and non-anxious MDD patients with healthy controls. Differences were detected in regional homogeneity, grey matter volume, and functional connectivity across brain regions associated with emotion regulation and cognition. An ML model using neuroimaging features effectively distinguished anxious from non-anxious MDD, offering insights into possible biomarkers for more precise diagnosis. In Gracia-Tabuenca et al. [24], a large adolescent dataset was analysed for predicting depression risk utilizing multimodal neuroimaging features from functional and structural MRI. Advanced ML methods were applied, and rigorous validation established that brain connectivity patterns, mainly from resting-state functional MRI, were most efficient in recognizing high-risk individuals. These findings highlight the significance of neural network interactions in understanding early depression risk. Gallo et al. [25] applied ML and DL techniques for differentiating MDD patients from healthy individuals utilizing large-scale resting-state neuroimaging datasets. Functional connectivity matrices were categorized using graph convolutional neural networks and support vector machines, attaining moderate accuracy levels. Results showed that thalamic connectivity played a vital role in classification, whereas other connections indicated weaker but reliable patterns. These findings emphasize the capability of computational approaches in recognizing neuro physiological markers of depression.

Mousavian et al. [26] proposed Smith-Atlas for identifying subject-specific resting-state networks (RSNs). For extracting discriminative features for depression detection, DL and connectivity-based methods are then applied. Various DL models, including Long Short-Term Memory (LSTM) networks, convolutional neural networks, and a well-known convolutional neural network architecture, are compared against a connectivity-based approach that uses subject-specific time series data for classifying MDD from healthy controls using rs-fMRI images. In Miholca and Onicas [27], depression detection is introduced through fMRI data collected from both healthy and depressed individuals during a music-listening task, a stimulus known for triggering reward-based brain responses. Given the limited application of ML, novel models are proposed that depend on Relational Association Rules and Artificial Neural Networks. For evaluating these models, a leave-one-out cross-validation approach is used, with experimental results proving promising performance when compared to existing methods.

Depression detection from sMRI and fMRI Images

Multimodal neuroimaging, such as functional and structural MRI scans, has been extensively explored for computer-aided MDD detection. Nevertheless, current studies often analyse these modalities distinctly, lacking their complementary potential. Although some approaches attempt integration, they did not consider data heterogeneity across modalities. An adaptive neuroimage integration framework is proposed in [28] that integrates functional and structural MRI features using DL techniques. This framework integrates a convolutional network for structural MRI, a graph-based model for functional connectivity, and dedicated modules for feature adaptation and feature fusion. It aims to decrease inter-modality differences and improve classification accuracy while detecting MDD. Early detection of MDD with the help of brain imaging can support clinicians in timely intervention. As depression is related to brain connectivity issues, an ML workflow is proposed in [29] that leverages spatial cube similarity from MRI scans as predictive features. This approach utilizes several similarity measures, including distance covariance and correlation-based techniques, for extracting discriminative features. These features are chosen with the help of statistical tests and fed into ML classifiers for prediction. Oversampling techniques are employed to address

imbalanced datasets. The framework is assessed on several independent datasets, representing its efficiency in MDD classification across diverse neuroimaging modalities. A computer-aided diagnosis model is developed in [30] that combines multimodal neuroimaging data for detecting MDD. In order to train feature representations from a large-scale dataset in two stages, a self-supervised contrastive learning framework is presented. First, feature knowledge is extracted through pretraining on a publically accessible dataset. After that, this information is refined for classification on a target dataset. Multimodal characteristics are fused using a two-stage integration technique, and the model's performance is thoroughly evaluated using a variety of assessment measures. To find important biomarkers linked to MDD, occlusion analysis is also carried out.

Comparison

The comparison of the existing depression detection approaches is given in Table 1.

Research Gaps

The research gaps identified from the literature are:

- As there is no commonly accepted, large-scale MRI dataset for detecting depression, model comparison, evaluation, and reproducibility is difficult. Hence, a publicly available benchmark dataset is required for consistent assessment.
- Although structural MRI features are extensively used, functional connectivity-based features are not analysed. More studies should examine dynamic connectivity patterns utilizing advanced DL architectures.
- Depression datasets have class imbalance problem, causing biased model performance. Effective cost-sensitive learning, resampling, or anomaly detection techniques must be explored further for improved model performance.
- Existing models did not efficiently distinguish between diverse subtypes of depression. Further research is required for developing fine-grained classification techniques that can capture differences in depressive symptoms.
- Inconsistency in MRI acquisition protocols across different hospitals impacts model performance. Future studies should concentrate on domain adaptation methods for improving generalizability across diverse MRI scanners.
- Several existing models depend on static MRI scans, failed to consider the temporal changes in brain structure and function. Hence, models that analyse progressive changes in MRI scans over time must be explored that could aid in early diagnosis.
- In spite of advancements in ML, limited studies incorporate AI models into real-world psychiatric diagnosis workflows. Henceforth, the research must cooperate with clinicians for developing accessible AI-assisted diagnostic tools.

Overcoming these research gaps and discovering the proposed future directions will progress the field of MRI-based depression detection, causing more precise, interpretable, and clinically pertinent diagnostic models.

CONCLUSION

This survey emphasizes the growing role of ML and DL techniques in the automated detection of depression through MRI images. Existing approaches are classified based on the MRI images used and approaches in each type is briefly discussed with advantages and limitations. These AI-driven approaches provide promising advancements in precision psychiatry by leveraging functional and structural neuroimaging data and enabling early diagnosis and personalized treatment strategies. However, in spite of significant progress, problems such as model interpretability, data heterogeneity, and lack of standardized validation affect clinical adoption. The lack of empirical evidence indicating enhanced patient outcomes further highlights the requirement for rigorous evaluation through randomized controlled trials. Future research must concentrate on improving model robustness, combining multi-modal imaging data, and refining interpretability to ensure reliable clinical implementation.

Table 1: Comparison of the Existing Depression Detection Approaches

Author (year) [ref]	Objective	Type	Method/Model Used	Advantages	Limitations
Wang et al. (2021) [14]	Major depression disorder diagnosis and analysis based on deep learning	sMRI	3D-DenseNet	Improved classification performance	Suboptimal performance of 2D networks
Mousavian et al. (2019) [15]	Depression Detection Using Feature Extraction and Deep Learning	sMRI	CNN, VGG16, Inception-v3	Augmentation improves classification	More computational cost
Hong et al. (2022) [16]	Automated MDD identification framework in sMRI data	sMRI	FRN-ResNet	Effective Feature Map Reconstruction	Struggle when applied to different datasets
Stolicyn et al. (2020) [17]	Automated classification of depression from structural brain measures	sMRI	SVM, penalised logistic regression or decision tree	Improved depression detection	Challenges in detecting remitted or lifetime MDD cases

Li et al. (2022)[20]	A resting state fMRI study of major depressive disorder with and without anxiety	fMRI	Statistical analysis	Explored brain correlates of MDD with and without anxiety	Lack of behavioural correlations
Galioulline et al. (2023)[21]	Predicting future depressive episodes from resting-state fMRI with generative embedding	fMRI	rDCM, SVM	Improved Predictive Performance	fMRI-based models alone did not offer clinically useful predictions
Wang et al. (2017) [22]	Depression Disorder Classification Using Sparse Low-Rank Functional Brain Network and Graph-Based Features	fMRI	SVM	Effective Feature Selection using Fisher score ranking	High Dimensionality of fMRI Data affect computationally intensive feature extraction and classification.
Zhou et al. (2024) [23]	Prediction of anxious depression using multimodal neuroimaging and machine learning	fMRI	Random forest	Provide potential biomarkers for accurate clinical diagnosis	Limited feature consideration
Gracia-Tabuenca et al. (2024) [24]	Predicting depression risk in early adolescence via multimodal brain imaging	fMRI	Advanced ML model	Promising predictive power for early-onset depression	Uncorrected predictors in multi-site data
Wang et al., (2022) [28]	Adaptive Multimodal Neuroimage Integration for Major Depression Disorder Detection	sMRI and fMRI	Graph convolutional network	Efficiently extract high-level features	Excludes Diffusion Tensor Imaging (DTI) data
Mousavian et al. (2021) [29]	Depression detection from sMRI and rs-fMRI images using machine learning	sMRI and fMRI	Bernoulli Naive Bayes (BNB)	Address dataset imbalance with random oversampling	Small training sample size
Li et al. (2024) [30]	Automated diagnosis of major depressive disorder with multi-modal MRIs based on contrastive learning	sMRI and fMRI	Contrastive learning	Robust classification performance	Struggle to symbolically express the role of DMN- and cerebellum-based regions as biomarkers
C.Flint et al., (2021) [31]	Quantifies how train and test sample sizes affect machine learning performance estimates in MRI-based MDD vs healthy control (HC) classification	sMRI	Support Vector Machine	It uses a large, multi-site, balanced structural MRI dataset (N = 1,868), giving strong statistical power and realistic estimates of achievable performance in MDD classification	Does not identify biomarker

ABSTRACT

Drug discovery and development is a time-consuming and costly process with a high rate of failure due to limitations related to safety, efficacy, and poor drug delivery. Conventional approaches largely depend on experimental trial-and-error methods, which increase development time and cost. In recent years, artificial intelligence (AI) has emerged as a useful tool to improve efficiency in pharmaceutical research. AI techniques such as machine learning enable rapid analysis of biological and chemical data, supporting target identification, virtual screening, and optimization of drug candidates. In parallel, novel drug delivery systems have significantly improved therapeutic outcomes. Nanocarrier-based platforms, including liposomes and polymeric nanoparticles, provide targeted delivery, controlled drug release, improved bioavailability, and reduced systemic toxicity. The integration of AI with drug delivery system design allows better prediction of formulation behavior and supports the development of targeted and stimuli-responsive delivery systems. This review briefly discusses the role of artificial intelligence in drug discovery and its application in the development of advanced drug delivery systems. Overall, AI-guided drug discovery combined with novel drug delivery strategies represents a promising approach for improving therapeutic efficiency in modern pharmacology.

Keywords: Artificial intelligence; Drug discovery; Drug delivery systems; Nanotechnology; Targeted drug delivery; Personalized medicine

INTRODUCTION

The technique of Recognizing among with improving new drugs is still complicated, highly resource- and Tedious. The techniques of Recognizing a lead product and getting approval for market usually takes ten to fifteen years. The significant technological, legal, and financial challenges that should be overcome during the method are shown by this lengthy schedule. Due to the significant expenses of R&D and adherence to regulations, financial investments in this pipeline sometimes surpass a million dollars [1]. These problems are not just costly; they also entail conquering a number of technological and analytical obstacles that can impede advancement and raise expenses. The method of drug expansion still faces many obstacles, especially in the form of increase drug testing of humans unsuccessful results, despite substantial advancements in science and technique. The main cause of these failures is persistent worries about the effectiveness and safety of chemicals. Maintaining the effectiveness and security of innovative therapies continues to be a crucial challenge that the industry must address, even while attempts to enhance the physical and chemical features of molecules have produced some gains [2]. This problem is made even more difficult when complicated illnesses like cancer are involved. The development of effective treatments is hampered by the wide parental and molecular heterogeneity that characterizes cancer. Drug discovery is made more difficult by the differences in molecular pathways and genetic data between patients with the same type of cancer as well as across various cancer types [3].

The hunt for novel approaches to maximize medication discovery must therefore be given top priority due to the severity and high frequency of cancer worldwide. The need to create more efficient and focused treatments that can handle the particular difficulties presented by cancer's heterogeneity is what motivates this objective. By allowing more accurate therapy targeting and increasing the production pipeline's capacity, the incorporation of cutting-edge methods and methodologies, like artificial intelligence and ML, inside the drug invention methods contains assurance for resolving some of these issues. Artificial intelligence (AI) has develop into a revolutionary tool that has the potential to greatly influence the study of drugs in this area. Renders it feasible to analyze large amounts of biological information, estimate interaction between molecules, and improve drug development with unprecedented accuracy through methods like machine learning (including convolutional neural networks [CNNs] and recurrent neural networks [RNNs]), deep learning, and advancing algorithms. This results in significant savings in time and money [4]. Individualized medicine is made possible by these technologies, which also make it easier to identify possible medication candidates, anticipate their effects, and customize therapies for each patient [5](Figure 1). The evolving landscape of AI-assisted drug discovery. Some icons are from NIAID BIOART Source (https://bioart.niaid.nih.gov/).Figure Reference [6].

AI for targeted and stimuli-responsive drug delivery

Quality requires an active approach employing ligands (antibodies and peptides) and stimuli-reactivity (pH, enzyme, and redox), which gives below passive selection. AI forecasts responses and speeds up the identification of targeting molecules. Ligand discovery and selection: Given the tremendously large multidimensional molecular gap among the intricate, non-linear system involved in molecular identification, the task of finding a strong atraction, highly particular ligand like a amino acids, immunoglobulin fragment, or low Molecular weight molecule that act on receptors that are specifically overproduced on cells with diseases is ideal for artificial intelligence. By using a prescriptive, creative, and knowledge-driven approach, AI goes beyond conventional brute-force scanning [7]. Models learned on multimodal datasets, Like molecular structure information from the PDB, biomolecular interaction binding attractions from sources like Adhesion DB, and genomic-proteomic representation pattern, use advanced virtual screening to evaluate millions of candidates in silico using complex algorithms like (GNNs) and (CNNs).These procedures assess off-target hazards to guarantee treatment safety by predicting crucial selectivity in addition to binding attraction.[8]

Optimizing stimuli-responsive systems

The improvement of "smart" drug delivery devices that function like small computers that simply release their pharmacological ingredient in action in particular biochemical inputs is the next stage in personalized medicine. For systems that are triggered by internal cues, such as an acidic pH of a tumor, elevated cytoplasmic glutathione, or elevated enzyme levels inside diseased tissue, the difficulties of design is to develop contents that are permanent in healthy tissue but undergo a precise structural shift at the target spot. The design must react to a particular biological threshold without premature release, making this an extremely complex multi-variable optimization problem. Because they can only investigate a very small portion of the enormous chemical design space and are unable to depict the unpredictable connections amongst nanoparticle design and chemical composition of polymers and the dynamic physiological milieu, conventional empirical methods find it difficult to negotiate such complexity. A prospective scenario approach is made possible by artificial intelligence, which is the best solution to this problem. Datasets that connect formulation characteristics (such as polymer pKa, cross-linking density, and linker chemistry) to release kinetics are used to train machine learning models like Random Forest and XGBoost. By revealing hidden structure-activity correlations, these models enable the inverse design of elements such as enzyme-specific amino acid linkers that reduce off-target cleavage or pH-sensitive shells for endosomal escape.[9,10,11]Figure.2

Convolutional Machine Network (CNN)

(CNNs) are one type of deep learning approach that is primarily utilized for the analysis of images. However, it can also be used for tasks related to drug research, including forecasting the characteristics of novel compounds. A CNN can handle complex and high-dimensional information even though it can naturally acquire and extract qualities from simple information.[16,17]

Recurrent Neural Network (RNN)

One kind of deep learning technique that is particularly good at handling sequential input is
recurrent neural networks (RNNs). By means on sequencing data, an RNN can be used in drug discovery to forecast the characteristics of novel molecules.[18] Generative Adversarial Network (GAN)A generative adversarial network (GAN), a type of deep learning technique, include of 2 neural networks the discriminator and the generator that have been adversarially trained to generate actual samples. GANs are employed in drug development to produce new chemical compounds with desired qualities. AI in Drug Investigation.[19]

AI for drug delivery system

Target Identification: In order to find possible medicinal property targets, AI systems can analyze a range of information sources that include clinical, proteomic and genomic information. By finding disease-related targets and molecular pathways, AI aids in the development of medications that can regulate natural processes.[20]

Virtual Screening: Virtual assessment Large substance databases can be efficiently screened using AI to identify treatment compounds that have a high chance of interacting to a certain location. AI saves both resources and time by modeling chemical reactivity and estimating binding strength, which aids scientists in selecting and categorizing substances throughout first testing.[21]

Structural Activity Relationship Modeling: (SAR): AI can recognize relationships among the constituent profile of A compound and its biological response. Investigators can enhance the possibility of capability treatments by creating molecules with required characteristics, like enhanced strength, reactivity, and advantageous physical and chemical qualities.[22]

DE - Novo Drug Design:

By using generative models and learning that takes place, AI algorithms can recommend novel chemical compounds that resemble medications. By combining data from trials and chemical libraries, AI extends the variety of Chemical prospects and facilitates the improvement of new drug participant. Evaluating medication Prospects: By considering a variety of factors, such as medications, safety, and reliability, AI algorithms may evaluate and enhance medication

candidates. This computationally approach assists researchers in increasing the effectiveness of pharmaceutical substances while lowering the likelihood of negative outcomes.[23]

Drug Repurposing: One notable utilization of AI in drug improvement is the assessment of enormous volumes of Medical details to find prescribed medicines with potential as treatments for a variety of diseases. Through the transformation strategy, AI reduces the expenses also expedites the drug identification process.[24]

Nanomaterials in Drug Delivery: Numerous nanomaterials with unique physicochemical characteristics and therapeutic benefits have been produced and tested for drug delivery applications [25]. Liposomes, polymeric nanoparticles, micelles, dendrimers, metallic nanostructures, and silica-based carriers are some of the most researched platforms, as demonstrated in Table.2 and Figure3 [26,27,28]. Together, these technologies allow for regulated administration of drugs, extended circulation, site-specific retention, and, in many situations, multiple uses like concurrent imaging and therapy [29]. Additionally, investigators can customize Nano carriers to certain therapeutic situations, such as cancer, infectious illnesses, and neurodegenerative disorders, because to their programmable properties [30,31]

Liposome: One of the first and most effective nanocarrier systems in clinical settings is liposomes. Both water-soluble and hydrophobic ingredients can be encapsulated in their biocompatible lipid bilayer, and surface adaptation with polyethylene glycol (PEGylation) prevents opsonin association and decreases absorption by the mononuclear phagocyte system (MPS), prolonging systemic circulation and decreasing immunological clearance.[33,34].

Polymeric Nanoparticle: Polymeric nanoparticles offer regulated and extended drug absorption. They are usually made of biodecomposable polymers like polycaprolactone or poly(lactic-co-glycolic acid) (PLGA). They enable exact drug disposition regulation, decreased both targeted tissue aggregation and general harm due to corresponding controllability in terminology of particle size, disintegration rate, and structural modification of the surface. [35]

Dendrimers: Dendrimers provide a highly branching, tree-like structure with one-dimensional surface functions and accurate molecular weight. Focusing on receptors or chemicals specifically is made possible by this well-defined structure's variable surface chemistry, multifaceted ligand expression, and extraordinarily high drug-loading capability[36].

Metallic Nanoparticle: A further level of utility in nanotechnology in medicine is offered by inorganic nanoparticles. Gold (AuNPs), silver (AgNPs), and iron oxide nanoparticles (IONPs) are examples of metallic nanoparticles (NPs) that have been thoroughly studied for drug delivery and theranostic utilizes that integrate immediate visualization with pharmacological payload delivery. [37,38].

Silica-Based Nanoparticle: In order to obtain synergistic therapy benefits, MSNs have been extensively studied for the delivery of several medicinal substances, including siRNA and chemotherapy medications. [39].

Carbon-Based Nanoparticle: Because of the special bonding characteristics of carbon compound's and nanoscale impacts carbon-based nanoparticles are used as drug carriers in a variety of different structural configurations. In particular, the dimensionality of their nanostructures is used to categorize these nanoparticles.[40]

AI technologies in cancer therapy: By improving the delivery of tiny medicines to attain and preserve ideal drug contents in the blood circulation and designated locations, artificial intelligence (AI) as well as related techniques have the capacity to completely transform cancer treatment [41].

Cancer nanomedicines: By merging pharmaceuticals with nanoscale innovation, cancer nanomedicine uses nanotechnology to detect, track, and treat cancer. By preserving focused therapy dosages, these developments may

be incorporated inside biological machinery, nanobiosensors, and medical apparatus, greatly enhancing the results of therapy in complex and deadly diseases.[42]

Nanomedicines for cancer AI technologies: The evaluated CURATE's viability. The PRECISE CURATEAI pilot clinical study uses AI to guide chemotherapy dosage in solid malignancies. This research demonstrated CURATE.AI's capacity to handle massive information issues in individual treatment by offering initial data on safety and effectiveness for forthcoming precision cancer trials.[43].

Ethical aspects of AI in therapy: AI have the ability to improve screening services and have a major influence on regions where physicians are in low supply. AI has the ability to transform treatment and direct future studies by identifying novel visualization biomarkers through the analysis of photographic images. Efficiency, accountability, ethics, rules, learning, approval, and safety are still issues, though.To serve tiny, distant medical facilities and reduce the strain in larger institutions, the Armed Forces Medical Services, for example, may incorporate AI-enabled diagnostic services given its different units and tasks. The effective implementation of AI depends on resolving challenges such IT integration, funding, software and hardware updates, training, and cybersecurity [44]

Ai/Ml Applications In C.N.S Drug Discovery

A class of neurological conditions known as CNS illnesses has a substantial economic and social impact. Contrary to other diseases, identifying new medications for CNS disorders presents particular difficulties, such as the intricacy of how the brain works, a lack of knowledge regarding the biology of the complex nature of CNS disorders, and the existence of the blood-brain barrier. Schizophrenia is arguably the most puzzling of psychiatric disorders[45].and In thisdrug discovery studies for schizophrenia, researchers have utilized AI/ML methods with various purposes, including drug target identification,[46,47]developing QSAR models,[48] .

Application Of Ai InThe Prediction And Prevention Of Diabetes

When as opposed to cultural analytical representation, machine learning (ML) is an exciting strategy that able to expand predictive execution. According to Choi et al., ML-based logistic modeling yielded an area under the curve (AUC) of 0.78 for estimating new-initiation diabetes inside five years for hospitalized patients. [49]

Blood glucose (BG) monitoring

The most common method is artificial neural networks, but other machine learning procedures like aid vector machines and random forests are being utilized more frequently. To evaluate the existing capacity of machine learning algorithms to forecast hypoglycaemia (i.e., detect hypoglycaemia potential before the signs arise), Kodama et al. conducted a meta-analysis [50].

Predictive Modeling and Optimization

Molecular and Computational Modeling: Despite beginning labor-intensive studies, molecular and computer models offer a basis for comprehending nanocarrier behavior in biological systems. Analyses of membrane access, endocytosis pathways, and drug dispensing processes are made possible by molecular dynamics (MD) simulations, which provide atomistic insights into nanoparticle interactions with lipid bilayers, proteins, and nucleic acids [51,52]

Machine Learning-Enhanced Prediction

A while back machine learning has been used to use vast Nanoparticle dissemination and elimination can be accurately predicted using preliminary datasets of physical and chemical properties and in vivo bioavailability. In order to estimate the organ-level distribution of various nanoparticles, such as gold, silica, and iron oxide, across several animal models, Wu et al. created a generalized physiologically based pharmacokinetic (PBPK) model combined with machine learning[53].

Formulation and Route Optimization: AI-powered Additionally, designs were selected used to enhance delivery routes and composition factors. ML algorithms can determine the best approach for a particular nanocarrier–drug mixture by examining datasets that compare oral, intravenous, subcutaneous, and inhalation paths [54].

Toward Precision and Personalized Nanomedicines: Forecasting modeling's next stage is customized healthcare. By integrating patient-specific genomic, epigenomic, and metabolomics profiles into AI-guided models, patient-specific nanocarriers can be produced[55].Such customization is particularly helpful in oncology, where tumor heterogeneity limits one-size-fits-as all approaches, and neurodegenerative diseases, because it is persistently difficult to cross the blood–brain barrier. Individualized planning may be beneficial for the development of nanomedicines that maximize potency while lowering harmful effects off-target.

Translational and Regulatory Perspectives: According to new findings, ML and DL models are more accurate than traditional screening techniques at predicting nanoparticle toxicity, biodistribution, and drug kinetics, which speeds up candidate selection and lowers the risk of clinical entrance [56].The quick development of interpretable AI (XAI) techniques, which improve model readability and offer clear justification for estimates, is equally significant. These developments promote repeatability, ease regulatory approval, and increase confidence between scientists and physicians[57].

AI in Smart DDS

AI is essential for creating intelligent drug delivery systems that can adjust to alterations in the body in real time. These systems can use sensors to track particular biological indicators (such as temperature or pH levels) and deliver medications in response. To improve targeting while reducing systemic exposure, pH-sensitive devices, for instance, are limited to dispensing restorative chemicals in acidic conditions, such as tumors or inflammatory tissues. Smart DDS may enhanced therapeutic outcomes by dynamically optimizing how drugs release through the integration of AI algorithms that assess real-time data from these sensors.[58]

AI in Patient-Specific DDS

AI has the ability to revolutionize individual healthcare by customizing drug delivery systems for each patient. AI can assist in creating DDS that are tailored to each patient's particular profile by analyzing genomic data, lifestyle factors, and medical histories. For example, machine learning algorithms can find genetic markers that affect the efficacy of drugs and metabolism, enabling medical professionals to tailor composition types and dosage schedules. This customization lowers the possibility of negative effects while increasing the efficacy of treatment.[59]

Scope Of Drug Delivery Systems

Drug Delivery Systems (DDS) have a wide range of applications for increasing the effectiveness of pharmaceutical goods, particularly in terms of directing the delivery of medications to their precise site to act and increasing accessibility throughout the body.

Targeted Drug Delivery

When a medication is taken using a traditional route, it circulates throughout the body and might or might not reach the intended location of impact. On occasion the drug is removed from the body before it can reach the site of effectiveness, which prevents the medication from reaching the minimal effective concentration for the action at that particular site.[60]Controlled and Sustained Release: Controlled and sustained release drug delivery systems are sophisticated medications designed to release active substances at a predetermined rate, ensuring effective treatment while minimizing side effects. These systems sustain a steady drug concentration in the bloodstream for prolonged periods of time, in contrast to conventional delivery methods that often result in varying medicine levels. Many of the methods used by controlled release systems to regulate drug release include diffusion, osmosis, and ion exchange. This allows for more precise targeting and greater absorption.[61]

Real-Time Monitoring

Drug release from nanoparticles can be monitored in real time thanks to developments in microfluidic systems like cell chips. Drug concentrations in physiological settings can be continuously analyzed thanks to these systems' integration of cultivating cells and drug delivery experiments. Data from these systems can be analyzed using AI algorithms to offers insights into cellular reactions and medication release kinetics, allowing for prompt treatment regimen modifications due to patient-specific data.[62]

Adaptive Drug Delivery: By enabling adaptive processes that react to physiological in nature alterations in real time, AI can improve DDS. Drug delivery systems that are temperature-sensitive or pH-responsive, for instance, can be made to release medications only in particular settings, like tumors. AI systems can rapidly modify the release profiles to maximize medical benefits while reducing adverse effects by continuously monitoring patient data (such as biomarker levels).[63]

Challenges in AI in Drug Discovery: Nanotechnology platforms, including micro micelles, nanoparticles, and liposomes, have been developed to overcome these obstacles and improve the amount of medication in the eye. Additionally, the development of artificial nanomotors and the application of natural motors, such sperm and bacteria, show promise for targeted medication delivery. Suchmotors have the potential to move about the body and deliver medications in particular places, minimizing exposure to healthy tissues and lowering negative impact.[64]

CONCLUSION AND SUMMARY

Artificial intelligence has become an important tool in modern pharmacology by improving both drug discovery and drug delivery processes. AI-based approaches support efficient data analysis, rational drug design, and optimization of drug candidates, reducing time and cost compared to conventional methods. When combined with novel drug delivery systems, AI contributes to the development of targeted and controlled therapies with improved safety and efficacy.Advanced drug delivery systems, particularly nanocarrier-based platforms, enhance drug stability, bioavailability, and site-specific delivery. The application of AI in designing these systems allows better prediction of formulation performance and supports the development of stimuli-responsive delivery strategies.Although challenges related to data quality, regulation, and ethical concerns remain, continued improvements in AI technologies are expected to strengthen their clinical application. In conclusion, the integration of artificial intelligence with novel drug delivery systems offers a practical and effective approach for advancing pharmaceutical research and improving patient-specific therapies in the future

ABSTRACT

Using transition probability analysis, this study focuses at the long-term sustainability of the Life Insurance Corporation of India's personnel structure during 2015-16 to 2024-25. Retention, promotion and leave probability were used in Markovian framework to characterize an annual manpower movement. In order to measure over a long labor stability time, a Manpower Sustainability Index (MSI) was established. Over the course of the investigation, empirical findings show a steady decrease in overall manpower combined with an increase in exit probability from 5% to 6.12%. Along with that, the MSI decreased from 19.75 to 15.96, suggesting deteriorating sustainability circumstances. In the absence of appropriate recruitment metrics, long-term forecasts based on average exit intensity predict that LIC workforce might decrease 91,606 in through workforce planning to ensure long-term operability and actuarial feasibility in public sector life insurance organizations.

Keywords: Sustainability, Manpower, Markovian framework, Manpower Sustainability Index, exit intensity.

INTRODUCTION

One of the most important key elements supporting operational stability in the life insurance industry is the long-term viability of human resources. In order to maintain business continuity, efficient policy servicing, successful underwriting practices and long-term financial stability, public sector insurance firms particularly LIC of India rely extensively organized labor systems. Manpower endurance is strongly connected to retention, personnel retention,

promotion techniques, and exit conduct over time in highly labourious personnel financial firms like LIC. In preference to privately held insurers, LIC has a more rigorous personnel structure system and a substantially strict organizational progression. However, concern about the long-term supply of experienced labor have been raised in recent years due to employee biological senility, forced retirements, declining recruitment, and heightened employee turnover. This could result in an imbalance between personnel inflow and outflow, which might eventually influence policyholder persistence, claim processing effectiveness, and underwriting standards all of which are essential from the standpoint of actuarial viability. From an institutional perspective, long-term personnel preservation means more than just keeping the same number of individuals; it also means making sure: adequate staff replenishment, balanced promotion flows, controlled extent of departure, and stable retention rates. LIC may experience a gradual loss of institutional knowledge capital if personnel departures consistently outpace internal progression and retention over time. This could raise operational hazard and administrative costs in the future.

Using secondary transition data on the following, the present investigation aims to delve the sustainability of LIC's labor system: Total workers, promotions, retention, and termination for the fiscal years 2015-16 to 2024-25. According to preliminary review of the data, the entirety of the workforce decreased from 1,11,000 in 2015-16 to 91,606 in 2024-25. This was accompanied by stable employee turnover indices that varied from roughly 5,200 to 6,600 per year. To establish if LIC's current human resource organization is long-term viable, such fundamental manpower dynamics demand for a stochastic modeling approach. Therefore, the purpose of this study is to examine whether the current promotion-retention-exit mechanism can sustain equilibrium workforce levels over time by examining manpower viability using a transition-based probabilistic approach.

LITERATURE REVIEW

From a tool for basic headcount estimation, the systematic development of manpower structures through mathematical modeling has developed into a critical basis for recognizing institutional viability. Stochastic structure foundations, contemporary matrix transformations, and the particular structural hazards of attrition in public sector financial firms are all widely discussed in the literature.

Classical Foundations of Stochastic Manpower Modelling

Bartholomew [2],Kumar [1]who illustrated that employee movement through a organizational framework is precisely recorded as a discrete-time Markov chain, pioneered the use of stochastic processes to evaluate human resource dynamics. This technique claims the memoryless property that an employee's rapid career transition is solely focused on their current position rather than prior employment, framing the personnel as a finite set of operating states. By establishing structural "wastage" (attrition) as an allowing state within the Markovian system, Vajda[5] enlarged this mathematical modeling an demonstrated that, absent proactive corporate techniques, human resource systems are exposed to natural decay over time.

Contemporary Advancements in Matrix Transitions:

These models' mathematical intricacy has increased recently, permitting them to represent intricate, multi-layered organizational frameworks. Rigid hierarchical organizations are especially susceptible to abrupt, pension-driven attrition shocks and demographic aging, according to Sharma and Mishra's [11] evaluation of public sector financial companies. Salehi-Rad and Dehghan-Nayeri [7] established multi-state Markov chain applications with absorbing states to simulate these business environments. When evaluating empirical, multi-year datasets, their research validates that considering separations as an absorbing condition produces accurate structural diagnostics and provides a strong framework for separating internal upward movement (promotions) from external waste (exits). Kemeny, J. G., & Snell, J. L. [3] illustratesfinite Markov chainsand Ross, S. M. [4]. states introduction to probability models.

Projections, Sustainability Indices, and System Stability

The transition from basic census tracking to formalizing workforce sustainability measures is a noteworthy development in recent research. A time-homogeneous Markov chain used across a ten-year longitudinal dataset provides a very dependable forecast horizon for detecting latent structural imbalances, as Al-Khouri and Harrison [9] showed. The institution is exposed to operational vulnerability when internal career mobility is not keeping up with systemic exits. According to Jarvi and Khayrutdinov's [8] research on human capital sustainability, a drop in worker retention indices is strongly correlated with an increase in institutional risk, endangering service continuity and fundamental operational capabilities. This offers the direct theoretical justification for using instruments such as the Manpower Sustainability Index (MSI) to identify structural deterioration prior to its detrimental effects on organizational performance.

Equilibrium Constraints and Recruitment Optimization

The published work's final limitation discusses how a contracting system can change course and reach a stable state. By demonstrating that a solely "wastage-only" system is mathematically guaranteed to contract unless a systematic, annual recruiting "source" vector is injected into the state space, Sekar and Swaminathan [10] solved talent supply chain optimization concerns. The most recent convergence proofs assessing the absolute mathematical bounds of organizational stability were released by Mehlmann and De Wilde [12]. According to their theorems, the long-term limit of the personnel system will unavoidably approach zero if the cumulative internal transition probability, which represents the total of the retention and promotion forces, falls below unity ($P_R + P_P < 1$). This structural dynamic emphasizes how crucial it is to assess public sector organizations like LIC in order to identify structural deterioration early and implement targeted policy changes. Nilakantan, K., & Raghavendra, N. [6] describes a review of stochastic models in human resource management.

Empirical Studies on LIC and Public Insurers

A changing demographic profile, marked by an increase in voluntary separations and an aging workforce, has been identified by empirical studies of LIC [13, 14]. According to the research currently in publication, a systematic replenishment program is necessary for large-scale financial institutions to prevent a decline in long-term operational efficiency due to a consistent exit level (varying between 5,200 and 6,600 annually in recent LIC statistics). By using a 10-year empirical dataset to assess the durability of these current trends, this effort expands upon these theoretical underpinnings.

METHODOLOGY

Data Source

The study is based on secondary data relating to manpower transitions in LIC for the period **FY 2015–16 to FY 2024–25**. The dataset includes

Conceptual Framework

The LIC workforce is viewed as a stochastic manpower system where workers shift between employment states over time in order to evaluate manpower sustainability.

It is presumed that every employee at LIC is from one of the following states: Active & Retained, Promoted, and Exit

A discrete-time Markov Chain can be used to describe the yearly transitions between these stages, where the future manpower structure is only dependent on the current state and not on previous transitions.

The following yearly probabilities are calculated using the observed data:

$$P_R(t) = \frac{\text{Retention}_t}{\text{Total Employees}_t}$$

$$P_P(t) = \frac{\text{Promotions}_t}{\text{Total Employees}_t}$$

$$P_E(t) = \frac{\text{Exit}_t}{\text{Total Employees}_t}$$

where, $P_R(t)$= Retention Probability , $P_P(t)$= Promotion Probability, $P_E(t)$= Exit Probability

Each fiscal year's workforce transition behavior is represented by these probabilities. Long-term sustainability cannot be explained by raw labor numbers alone. Converting the measured numbers into transition probabilities is hence the first step. Using the information you provided, the following probabilities are computed for each fiscal year t:

Retention Probability

This is the proportion of workers who stay with LIC.

$$P_R(t) = \frac{\text{Retention}_t}{\text{Total Employees}_t}$$

Example (FY 2015–16):

$$P_R = \frac{105450}{111000} = 0.9495$$

Interpretation: This year, LIC kept over 94.95% of its workforce.

Promotion Probability

This shows the percentage of workers who advance to higher grades.

$$P_P(t) = \frac{\text{Promotions}_t}{\text{Total Employees}_t}$$

Example:

$$P_P = \frac{4200}{111000} = 0.0378$$

Interpretation: Approximately 3.78% of workers had upward mobility.

Exit Probability

This shows the percentage of workers quitting LIC as a result of: Retirement, Voluntary resignation, Death, and Other separations

$$P_E(t) = \frac{\text{Exit}_t}{\text{Total Employees}_t}$$

Example:

$$P_E = \frac{5550}{111000} = 0.0500$$

Interpretation: Throughout the year, almost 5% of the workforce left LIC.

Construction of Transition Probability Matrix

The manpower system can then be represented through the transition probability matrix:

$$P = \begin{bmatrix} P_R & P_P & P_E \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

This matrix captures the movement of employees from: Active state → Retained, Active state → Promotion, and Active state → Exit

Example:

FY 2015–16 $T_{2015-16} = \begin{bmatrix} 0.9500 & 0.0378 & 0.0500 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$

FY 2016–17 $T_{2016-17} = \begin{bmatrix} 0.9500 & 0.0377 & 0.0500 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$

FY 2017–18 $T_{2017-18} = \begin{bmatrix} 0.9536 & 0.0384 & 0.0464 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$

FY 2018–19 $T_{2018-19} = \begin{bmatrix} 0.9529 & 0.0384 & 0.0471 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$

FY 2019–20 $T_{2019-20} = \begin{bmatrix} 0.9476 & 0.0380 & 0.0524 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$

FY 2020–21 $T_{2020-21} = \begin{bmatrix} 0.9469 & 0.0376 & 0.0531 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$

FY 2021–22 $T_{2021-22} = \begin{bmatrix} 0.9420 & 0.0380 & 0.0580 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$

FY 2022–23 $T_{2022-23} = \begin{bmatrix} 0.9445 & 0.0386 & 0.0555 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$

FY 2023–24 $T_{2023-24} = \begin{bmatrix} 0.9325 & 0.0375 & 0.0675 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$

FY 2024–25 $T_{2024-25} = \begin{bmatrix} 0.9388 & 0.0382 & 0.0612 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$

Average Transition Probability Matrix

For long-run analysis, we first compute the **average transition probabilities** from FY 2015–16 to 2024–25.

From the given matrices:

$$\bar{P_R} = 0.9459, \quad \bar{P_P} = 0.0380, \quad \bar{P_E} = 0.0541$$

Hence, the **Average Transition Matrix** becomes:

$$\bar{T} = \begin{bmatrix} 0.9459 & 0.0380 & 0.0541 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Long-Run Manpower Projection Model

Let:M_t = Total manpower at year t

Since both retained and promoted employees remain within LIC system,future manpower depends only on exit probability:$M_{t+1} = M_t(P_R + P_P)$

By the Law of Total Probability,$P_R + P_P + P_E = 1$

Therefore,$P_R + P_P = 1 - P_E$ .Hence,$M_{t+1} = M_t(1 - \bar{P_E})$Substituting:

$$M_{t+1} = M_t(1 - 0.0541)$$
$$M_{t+1} = 0.9459M_t$$

Long-Run Sustainability Analysis

Let:M_t = Total manpower at year t.Since both retained and promoted employees remain within LIC system, future manpower depends only on exit probability:

$M_{t+1} = M_t(P_R + P_P)$.But:$P_R + P_P = 1 - P_E$.Therefore,$M_{t+1} = M_t(1 - \bar{P_E})$.

Hence,$M_{t+1} = M_t(1 - 0.0541)M_{t+1} = 0.9459M_t$

Long-Run Sustainability Function

Multi-Year Iteration (n Years)

To find the level for n years, we apply this logic repeatedly (iteratively):

- **Year 1:**$M_{t+1} = M_t\,(1 - P_E)$
- **Year 2:**$M_{t+2} = M_{t+1}\,(1 - P_E) = [M_t\,(1 - P_E)]\,(1 - P_E) = M_t\,(1 - P_E)^2$
- **Year 3:**$M_{t+3} = M_{t+2}\,(1 - P_E) = M_t\,(1 - P_E)^3$

This geometric trend leads to the following general formula for any future year n:

$$M_{t+n} = M_t\,(1 - P_E)^n$$

Iterating repeatedly, we get $M_{t+n} = M_t(0.9459)^n$

Sustainability Behaviour

Since $0.9459 < 1$, $\lim_{n\to\infty} M_{t+n} = 0$

This suggests, in the lack of new hires, the LIC manpower system gradually deteriorates over time.

Practical Interpretation

Initial manpower (2024–25):$M_0 = 91{,}606$

After 10 years:$M_{10} = 91606(0.9459)^{10}$

$M_{10} \approx 91606(0.573)$

$M_{10} \approx 52{,}500$

Thus:

- LIC manpower reduces nearly 43% in 10 years
- Workforce approaches a declining equilibrium

Sustainability Condition:

A manpower system is sustainable only if $P_R + P_P \geq 1$.

But here, $P_R + P_P = 0.9839 < 1$

Thus, under the current transition mechanism, the LIC manpower system is not long-term viable.

Steady State Behaviour

LIC's manpower system's sustainability state is assessed by determining whether

$$\lim_{t\to\infty} M_t = M^* \text{ exists and remains stable.}$$

The system is deemed sustainable if the number of workers reaches a steady level.

The system shows long-term instability if manpower is consistently declining, suggesting that recruitment or retention policies need to be adjusted. need for recruitment or retention policy adjustments.

Manpower Sustainability Index

A Manpower Sustainability Index (MSI) is defined as:

$$MSI = \frac{P_R + P_P}{P_E}$$

- $MSI > 1 \rightarrow$ Sustainable manpower system
- $MSI = 1 \rightarrow$ Equilibrium
- $MSI < 1 \rightarrow$ Unsustainable system

CONCLUSION

According to the empirical data, LIC is presently experiencing long-term instability. Over the course of 10 years, the sustainability index has decreased by about 19% due to the combination of falling retention rates and rising exit intensities. The overall workforce will continue to trend toward zero in the absence of intentional hiring to serve as an outside "source" of man power.

ABSTRACT

Erratic and irregular availability of surface water leads to large scale exploration for groundwater in recent times. Increasing demand for water supply necessitates the utilization of advanced and scientific techniques that are capable of saving time and money to identify the groundwater prospective. Serchhip district of Mizoram, India received abundant rainfall. However, rapid growth of human population and rapid urbanization within the district leads to acute shortage of water resources. Therefore, groundwater resources need to be utilized to facilitate this persistent scarcity of water supply. The first and foremost step in utilizing groundwater is to delineate its location beneath the surface. The present study makes use of Geospatial technology like utilization of geographic information systems (GIS) and remote sensing data to detect the promising sites for groundwater exploration. Geospatial factors which are responsible for the occurrence of groundwater within the district were identified. Land use / land cover, slope morpho metry, geomorphology, lithology, geological structures like faults and lineaments layers were generated. These thematic layers were assigned different ranks based on their relative importance in deriving the potentiality of groundwater. Different classes within each thematic layer were assigned weigth ages in numerical rating from 1 to 10 as attribute values in GIS environment. Summation of these attributes values, and the corresponding rank values of the thematic layers were utilized to generate the

final groundwater potential map. This final map shows the different classes of ground water potential zones within the district which can be utilized for exploration and further development of groundwater resources.

Keywords: Geospatial technology, GIS, Groundwater, Remote Sensing, Serchhip district

INTRODUCTION

Springs are natural groundwater discharge points formed where aquifers intersect the land surface, allowing water to emerge through pores, fractures, fissures, and depressions in mountainous terrains. In the mid-hills of the Hindu Kush Himalayas (HKH), springs constitute the principal source of freshwater, fulfilling more than 90% of domestic water requirements for millions of people. Recent studies have highlighted growing concerns regarding the progressive decline in spring discharge and the increasing seasonality of spring flows, although comprehensive quantitative assessments remain limited. This reduction in spring yield has adversely affected household water availability in remote settlements and diminished agricultural productivity, as springs also serve as critical sources of irrigation. Consequently, the degradation of Himalayan Spring systems and associated groundwater resources poses a significant threat to the long-term water security of mountain communities and downstream regions, including the Indo-Gangetic plains (NITI Aayog, 2021). In Mizoram also, Springs (Tuikhur' in Mizo) are the most important sources of water supply in since time immemorial. Even though the government has been providing drinking water supply in various parts of the state, the age-old method of fetching water from natural springs for domestic purposes is still prevalent in many parts of the state. Springs have also been profoundly utilized for irrigation purposes. Generally, springs located within or near the periphery of settlement area are utilized for tapping drinking water and for irrigation purposes.

Mizoram used to receive sufficient amount of rain water and used to have numerous perennial springs unlike many other states in the country. However, the quality and quantity of water seem to be deteriorating owing to dynamic climatic conditions, deforestation and other anthropogenic activities. This unreliable and declining availability of water harshly affects domestic and agricultural water supply in recent years. Rural hardship due to water scarcity is still a major problem and this calls for identification and hence inventory and assessment of springs and implementation of sprished development has been the need of the hour. To formulate scientific strategies for sustainable development, an information system regarding the natural springs has become highly crucial. Based on this information recharging of springs has been carried out in Chhuanthar habitation of Mizoram. Geologically, Mizoram state comprises N-S trending ridges with high degree of slopes and narrow intervening synclinal valleys, faulting in many areas has produced steep fault scarps (GSI, 2011). Hence, Serchhip district also in general, experienced acute shortage of groundwater as the monsoon rainfall is rapidly lost as surface runoff. Therefore, groundwater potential zones have to be identified so as to adopt proper measures for its conservation and development.

Few efforts were made to study groundwater prospect zones within the state of Mizoram. These include Hydrogeological mapping of Aizawl city, Aizawl district (DG&MR, 2003) and Hydrogeological mapping of Champhai town, Champhai district (DG&MR, 2004). Advent of geospatial technology like utilization of Remote Sensing and GIS allow fast and cost-effective survey and management for natural resources (Ramakrishna et. al., 2013). Hence, these techniques have wide-range applications in the field of geo-sciences including groundwater prospecting (Anirudh, 2013). GIS techniques can be utilized to delineation groundwater prospect zones by overlaying various geospatial data (Soumen Dey, 2014). Therefore, many researchers have utilized these two techniques successfully in groundwater studies (Gustafsson,1993; Saraf and Jain, 1994;Krishnamurthy and Srinivas 1995, Krishnamurthy et. al., 2014). The same techniques have been proved to be of immense value not only in the

field of hydrogeology but also for the development of surface water resources as well. (Saraf and Choudhury, 1998; Sharma and Kujur, 2012).

Study Area

The study area is located within Serchhip district in the central part of Mizoram, extending more to the eastern side. It falls in the Survey of India Topo sheet Nos. 84 A/14.

Thearea enjoys a moderate climate owing to its tropical location. It is neither very hot nor too cold throughout the year. The entire district falls under the direct influence of the south west monsoon. As such the area receives an adequate amount of rainfall which is responsible for a humid tropical climate characterized by short winter and long summer with heavy rainfall. The average annual rainfall of the study area is 2233.30m (Lalrinhlua).

Objectives of the Study

Springs are one of the most important water sources in Mizoram and play vital role in rural water security. However, the number and discharge of springs are declining. Hence, in-depth study of the springs and their recharge potential area and executing recharge measures for reviving the springs is the need of the hour. The study will serve as a pilot work in such regards. The objectives of the present study were twofold: first, to provide a better understanding of the basic characteristics of these springs by undertaking an extensive survey, and secondly, based on the study, sustainability measures are taken and the output of springshed developmental work is documented.

MATERIALS AND METHODS

Data used

Conventional hydro geological investigation data of the study area plays the basic information. Moreover,Cartosat-2S data having spatial resolution of 0.6m is used. SOI topographical maps and various ancillary data were also referred in this study.

Thematic layers

Thematic layers like land use/land cover, slope, hydro geological are generated to be integrated in a Geographic Information System (GIS) environment. The different layers are as follows- Land use / Land cover:Land use/land cover plays an important role in facilitating natural groundwater recharge to the aquifers (Anirudh, 2013; Sidhu and Rishi, 2014). Forest, pastures and grasslands, and water bodies are important for groundwater recharge. Impermeable pavements and other structures due to urbanization act as obstacles to natural recharge process. Infiltration and runoff are greatly depending on land use/land cover. It is well known that recharge is high in the cultivable land and irrigated land compared to the wasteland and settlements. (NRAA, 2011; Valliammai et al., 2013). Land use/land cover map also plays important role in identifying the site for implementation or recharge structures. Slope: Slope map was generated utilizing the Cartosat-2S stereo-paired data in a GIS environment. The area isdivided into eight slope classes, viz., 0-5, 5-10, 10-200, 20-30, 30-35, 35-45 and above 45 degrees.Gentle slope promotes water infiltration and groundwater recharge whereas steep slopes acts as a high runoff zone (CGWB, 2000; Kumar and Kumar, 2011; Siddalingamurthy et. al., 2013). Slope angle values considered for selecting recharge method. The slope map is shown in Figure 3.

Hydrogeology: Hydrogeological assessment is the most important features in sring developmental ctivities. It has also been utilized in managing groundwater resources (Kumar and Kumar 2011; Valliammai et al., 2013, Raju et al., 2013). It is also highly helpful for selecting the artificial recharge sites(Ghayoumian, 2007). The study area was comprisedfour main hydrogeolical units which are intermontane valley, Less Dissected Structural Hill, Moderately Dissected Structural Hill and Highly Dissected Structural Hill. High elevated areas are less suitable for occurrence of groundwater (Edet et al., 1998; El-Baz, 1999). However those areas an be good potential site for implementing recharge structure Hydrogeological map of the study area is shown in Fig. 4.

Aspect: Slope aspect plays an important role in controlling spring occurrence, discharge, and water quality because it influences the amount of solar radiation received, evapo transpiration, soil moisture, weathering processes, vegetation cover, and groundwater recharge. Slope aspect is an important physiographic parameter influencing groundwater flow, drainage patterns, and springshed development in mountainous regions. In the Himalayan springsheds of Kalimpong and Bhurung, slope orientation governs the direction of drainage networks and controls the movement of spring water through the landscape, thereby influencing watershed hydrology and the connectivity between springs and stream channels.(Tewari et. al, 2026)

Soil: Soil type is one of the most important factors controlling groundwater occurrence, recharge, storage, and hydrochemistry because it determines infiltration capacity, porosity, permeability, and the movement of dissolved minerals and contaminants. Different soil types influence groundwater recharge and storage through variations in permeability and hydraulic conductivity. Sandy and gravelly soils generally facilitate groundwater replenishment because rainwater infiltrates quickly into the subsurface. In contrast, clay-rich soils impede downward percolation, resulting in greater surface runoff and lower groundwater recharge. Studies have shown that groundwater recharge is inversely related to clay content and positively correlated with well-drained soils. (Nolan et. al, 2003). Soil hydraulic properties, including saturated hydraulic conductivity and soil texture, strongly control groundwater recharge under different climatic conditions. Fine-textured soils exhibit a more pronounced decline in recharge during dry periods than coarse-textured soils. In hilly terrains, groundwater recharge patterns are governed by interactions among soil thickness, permeability, and bedrock properties, leading to significant spatial variability in spring discharge and aquifer replenishment. (Willemijn et. al, 2025). Soils act both as natural filters and as sources of dissolved constituents. Coarse-textured sandy soils permit rapid infiltration and therefore allow contaminants such as nitrate and pesticides to reach aquifers more easily. Clay-rich soils, owing to their higher adsorption capacity, can retain pollutants but may also increase the residence time of dissolved salts. (Bernard, et. al, 2003). Groundwater chemistry is strongly influenced by recharge pathways and soil–rock interactions. Variations in nutrient concentrations, major ions, and total dissolved solids (TDS) are controlled by the composition of the overlying soil and aquifer materials. (Broekhoven et. al., 2024). Recent hydro geochemical studies in hard-rock aquifers have also demonstrated that soil characteristics, land use, and monsoonal recharge collectively influence groundwater quality parameters such as electrical conductivity, alkalinity, hardness, calcium, magnesium, and chloride concentrations. (Rajmohan et. al, 2025).

Data Analysis

The delineation of suitable recharge zones and springshed development sites was carried out through an integrated geospatial and hydrogeological analysis within a Geographic Information System (GIS) environment. Multiple thematic layers representing the major factors controlling groundwater recharge and spring occurrence were prepared from satellite data, field investigations, topographic information, and existing hydrogeological records. These layers included land use/land cover, slope, hydrogeology, lithology, soil characteristics, slope aspect, and geological structures (faults, fractures, and lineaments). Each thematic layer was classified into different categories according to its relative influence on groundwater recharge and spring sustainability. For example, dense forest cover, permeable sandstone formations, gentle slopes, well-drained soils, and structurally controlled fractured zones were considered more favourable for infiltration and groundwater storage, whereas steep slopes, shale-dominated formations, highly dissected terrain, and impermeable soils were assigned lower suitability due to increased surface runoff and limited infiltration. The relative importance of each thematic layer and its respective classes was assigned using a knowledge-driven weighted overlay approach based on hydrogeological principles, previous research, and expert judgement (Neelakantan and Yuvaraj, 2012; Krishna Murthy and Renuka Prasad, 2014). Numerical weights and ranking values were allocated according to the expected contribution of each parameter to groundwater recharge and spring discharge. Parameters exerting greater control on groundwater occurrence, such as hydrogeology, geological structures, lithology, and slope, were assigned comparatively higher weights than secondary controlling factors such as land use, aspect, and soil characteristics.

RESULTS AND DISCUSSION

Identification of Recharge Zones Using Geospatial Analysis: The integrated GIS-based analysis successfully delineated suitable recharge zones within the Chhuanthar Springshed by combining land use/land cover, slope, hydrogeology, soil characteristics, aspect, and geological structures. The weighted overlay approach revealed that groundwater recharge potential is primarily governed by the interaction between topography, lithology, structural discontinuities, and vegetation cover. The most favourable recharge zones are characterized by gentle to moderately sloping terrain (generally less than 20°), dense forest or natural vegetation cover, highly permeable soils, sandstone-dominated lithology, intersections of fractures, joints, and lineaments, recharge areas located immediately upslope of spring outlets. These conditions collectively enhance rainfall infiltration, increase groundwater residence time, and promote subsurface storage before groundwater discharges through springs. Conversely, steep hill slopes, highly dissected structural hills, shale-dominated formations, and areas with limited soil development exhibited poor recharge potential because intense surface runoff reduces infiltration opportunities despite receiving high annual rainfall. This finding confirms that rainfall alone does not determine groundwater availability; rather, geological and geomorphological conditions largely control groundwater storage and movement in mountainous terrains. The identified recharge zones were therefore selected for implementing recharge interventions such as contour trenches, staggered trenches, recharge pits, vegetative measures, and infiltration structures designed to increase infiltration and reduce rapid runoff.

Hydrogeological Significance of Recharge Site Selection: The hydrogeological investigation demonstrated that structural geology plays a dominant role in spring occurrence within the study area. Most perennial springs occur where fractured sandstone units intersect hill slopes, allowing groundwater stored within secondary porosity to emerge naturally at the surface. Although sandstone generally possesses relatively higher primary porosity than shale, groundwater occurrence in Mizoram is largely controlled by secondary permeability developed through joints, fractures, and fault systems. Consequently, recharge structures constructed near major fracture intersections significantly enhance recharge efficiency by directing infiltrated rainwater into these preferential groundwater flow pathways. The spatial relationship observed between recharge structures and geological discontinuities supports previous studies indicating that structural control is one of the most influential factors governing spring sustainability in hard-rock and folded mountain terrains.

Effectiveness of Springshed Interventions: Comparison of spring discharge before and after implementation of recharge measures demonstrated a noticeable improvement in spring yield. The increase in discharge indicates that the recharge interventions effectively enhanced groundwater replenishment within the springshed. The improvement can be attributed to several complementary processes like increased infiltration of monsoon runoff, reduced surface runoff velocity, prolonged groundwater residence time, and improved soil moisture storage, enhanced recharge into fractured sandstone aquifers. Rather than rapidly leaving the catchment as surface runoff, a larger proportion of rainfall infiltrated into the subsurface, gradually contributing to sustained spring discharge during the dry season. Although seasonal fluctuations continue to occur due to climatic variability, the observed increase in discharge suggests that scientifically planned springshed management can substantially improve water availability in mountainous watersheds. The present study therefore demonstrates that recharge structures alone are insufficient; their effectiveness depends largely on selecting hydrogeologically appropriate locations through detailed spatial analysis.

Water Quality Response: Water quality analyses conducted before and after implementation showed no significant deterioration in any of the measured physico-chemical parameters. The analysed parameters remained within desirable drinking water limits, indicating that the recharge interventions did not introduce adverse hydrochemical changes. This observation suggests that the recharge structures primarily enhanced natural infiltration through existing soil and weathered rock profiles, allowing adequate natural filtration before groundwater reached the aquifer. The absence of significant changes in groundwater chemistry also indicates that appropriately designed

recharge structures can improve groundwater availability without compromising water quality, provided that recharge occurs through uncontaminated catchments. These findings agree with previous artificial recharge studies which reported that properly located recharge interventions generally improve groundwater storage while maintaining acceptable hydrochemical conditions.

Implications for Springshed Management: The present study demonstrates that geospatial technology provides a reliable and cost-effective decision-support system for springshed development in mountainous regions. Traditional approaches frequently rely on visual field observations for locating recharge structures, often resulting in sub-optimal performance. In contrast, GIS-based integration of hydrogeological parameters enables objective identification of recharge zones with higher groundwater recharge potential. The methodology developed in this study is particularly suitable for the folded sedimentary terrain of Mizoram, where groundwater occurrence is highly localized and controlled by geological structures. The approach can be replicated across other spring-dependent regions of Northeast India and the Himalayan belt, providing an efficient framework for planning spring rejuvenation programmes under climate variability and increasing water demand. Nevertheless, long-term monitoring remains essential to evaluate seasonal variations in discharge and to quantify recharge efficiency under different rainfall conditions.

CONCLUSION

This study demonstrates the successful application of geospatial technology and hydrogeological investigation for Springshed development in the Chhuanthar habitation of Serchhip District, Mizoram. Integration of land use/land cover, slope, hydrogeology, soil characteristics, aspect, lithology, and geological structures within a GIS environment enabled accurate delineation of groundwater recharge zones and scientifically guided the placement of recharge interventions. The post-intervention assessment revealed a measurable improvement in spring discharge, indicating enhanced groundwater recharge and increased aquifer storage. Simultaneously, water quality remained within desirable limits, confirming that appropriately designed recharge structures do not adversely affect groundwater chemistry. These findings emphasize that the success of springshed development depends not only on the construction of recharge structures but also on proper understanding of the hydrogeological setting and accurate selection of recharge locations. The study further demonstrates that structural discontinuities, favourable lithology, gentle slopes, permeable soils, and natural vegetation collectively control groundwater recharge in the folded sedimentary terrain of Mizoram. Among these factors, geological structures and hydrogeological conditions exert the strongest influence on spring sustainability.

The methodology adopted in this study provides a scientifically robust and cost-effective framework for planning springshed management in mountainous regions where groundwater occurrence is highly heterogeneous. The integrated use of Remote Sensing, GIS, and field hydrogeological investigations significantly reduces uncertainty in site selection and improves the efficiency of groundwater conservation measures. Given the increasing impacts of climate variability, population growth, and land-use change on mountain water resources, this integrated approach has considerable potential for large-scale implementation across Mizoram and other Himalayan regions. Future studies should incorporate long-term hydrological monitoring, groundwater level observations, environmental isotope techniques, and numerical groundwater modelling to quantify recharge processes and evaluate the long-term sustainability of spring rejuvenation programmes. Such investigations will further strengthen scientific understanding and support evidence-based water resource management for climate-resilient mountain communities.

Outcome

Discharges of all the springs were compared before and after the intervention of recharging activities. There significant increases in the rate of discharge of springs which is a sign for successfully implementing recharge techniques as well as selecting the vital locations for constructing recharge structures. However, the suitability or consistent rate of discharge is the most important parameters for measuring the purpose of the entire exercise.

Moreover, the water quality remains the same which means that all the parameters still fall within the desirable limit indicating the artificial recharge structures do not have adverse effect regarding the spring water quality.

ABSTRACT

Seasonal multi cropping under drip irrigation requires simultaneous consideration of crop productivity, economic return, soil characteristics, climatic variability, fertilizer management and irrigation water use. This paper presents the Neuro-EvoSwarm Optimizer (NESO), a hybrid decision-support framework that integrates Deep Learning (DL), Genetic Algorithm (GA) and Particle Swarm Optimization (PSO). The framework first preprocesses agricultural data by handling missing or inconsistent records, encoding categorical variables, scaling numerical features and selecting relevant attributes. A Deep Learning prediction module estimates crop yield and economic profit from soil, climatic, crop-management and irrigation variables. The predicted values are then used by a Genetic Algorithm to explore a large search space of seasonal crop combinations. The best candidate strategies generated by GA are transferred to PSO, which refines the solutions using personal-best and global-best learning. The optimization objective is formulated to maximize crop yield and economic profit while minimizing irrigation water requirement. The final decision-support output consists of a recommended seasonal crop combination, predicted yield, expected profit and water requirement. The proposed modular framework is intended for sustainable agricultural planning and can be adapted to different soil types, climatic conditions, seasons and irrigation environments. The framework provides a structured computational approach for integrating prediction and multi-objective optimization in precision agriculture.

Keywords: Neuro-EvoSwarm Optimizer, Deep Learning, Genetic Algorithm, Particle Swarm Optimization, Multicropping, Drip Irrigation, Precision Agriculture

INTRODUCTION

Agricultural decision-making is influenced by interacting soil, climate, crop and resource-management variables. In seasonal multi cropping systems, selecting an appropriate crop combination is more complex than selecting a single crop because productivity, profitability and water demand must be considered simultaneously. Drip irrigation can improve water-use efficiency, but effective crop planning still requires an intelligent method for matching crop choices with soil and climatic conditions. Conventional planning approaches may rely on historical averages, expert judgement or independent optimization of a single objective. Such approaches may not adequately represent nonlinear relationships between environmental variables, crop management and economic outcomes. Machine learning can learn complex relationships from agricultural data, while evolutionary and swarm-based optimization methods can search large decision spaces. The proposed Neuro-EvoSwarm Optimizer (NESO) combines these capabilities. Deep Learning is used as a predictive layer for estimating crop yield and expected economic profit. Genetic Algorithm is used to explore candidate seasonal multi cropping strategies, and Particle Swarm Optimization is used to refine the best GA solutions. Thus, prediction and optimization are integrated into one decision-support framework. The main objectives of the proposed work are: (i) to develop a unified agricultural data-processing and prediction framework; (ii) to estimate crop yield and economic profit using Deep Learning; (iii) to generate and evaluate seasonal multi cropping strategies using GA; (iv) to refine promising solutions using PSO; and (v) to balance productivity, profitability and irrigation-water requirements under drip irrigation.

MATERIALS AND METHODS

Agricultural Data Representation

The framework considers agricultural attributes representing soil, climate, crop management and irrigation conditions. The major variables include soil type, soil pH, organic carbon, clay percentage, maximum temperature, minimum temperature, rainfall, relative humidity, season, crop type, nitrogen, phosphorus, potassium and irrigation water usage. The target variables are total crop yield and total economic profit.

- Soil variables: soil type, soil pH, soil organic carbon and clay percentage.
- Climate variables: maximum temperature, minimum temperature, rainfall and relative humidity.
- Crop-management variables: season, crop type and fertilizer application (N, P and K).
- Resource variable: irrigation water usage.
- Optimization targets: crop yield, economic profit and irrigation-water requirement.

Data Preprocessing

Before model training, the agricultural data are processed to improve consistency and numerical stability. The preprocessing pipeline includes missing-value handling, detection of inconsistent records and outliers, categorical encoding, feature scaling and normalization. Relevant features are subsequently selected for model development.

Feature selection focuses on variables that are expected to have a meaningful influence on crop performance, including climatic conditions, fertilizer application, irrigation-water usage and seasonal information. The resulting feature set is supplied to the prediction module.

Deep Learning Prediction Module

The Deep Learning module learns nonlinear relationships between agricultural input variables and the target variables. For each candidate agricultural condition, the model estimates expected crop yield and expected economic profit. These predictions are used as fitness information during optimization.

Conceptually, the prediction function can be represented as:

$\hat{y} = f\theta(X)$

where X represents the selected agricultural input features, $f\theta$ represents the trained Deep Learning model, and $\hat{y}$ represents the predicted agricultural outcome.

Genetic Algorithm Optimization

The Genetic Algorithm represents a seasonal multi cropping strategy as a chromosome. An initial population of candidate strategies is generated and evaluated. Selection, crossover and mutation are applied to produce new candidate solutions. Low-quality strategies are progressively eliminated, while high-quality strategies are retained.

The fitness function is designed as a multi-objective measure. A general weighted formulation is:

$$F = w_1Y + w_2P - w_3W$$

where Y is predicted yield, P is predicted economic profit, W is irrigation-water requirement, and w_1, w_2 and w_3 are user-defined weights. Higher fitness indicates a more desirable balance between productivity, profitability and water use.

Particle Swarm Optimization Refinement

The best candidate strategies obtained from GA are used to initialize the PSO search. Each particle represents a candidate crop-allocation strategy. Particles update their positions based on their personal best solution and the global best solution identified by the swarm. This refinement stage is intended to improve the quality of promising GA solutions and accelerate convergence toward a high-quality solution.

The conceptual PSO update is represented by:

$v_i(t+1) = \omega v_i(t) + c_1r_1[pbest_i - x_i(t)] + c_2r_2[gbest - x_i(t)]$

$x_i(t+1) = x_i(t) + v_i(t+1)$

where x_i is the particle position, v_i is particle velocity, $pbest_i$ is the personal best, gbest is the global best, ω is the inertia weight, c_1 and c_2 are learning coefficients, and r_1 and r_2 are random values in [0,1].

NESO Workflow

- Load the agricultural dataset.
- Clean, encode, scale and normalize the data.
- Select relevant agricultural features.
- Train the Deep Learning prediction model.
- Generate candidate seasonal multi cropping strategies.
- Evaluate candidate strategies using predicted yield, profit and water use.
- Apply GA selection, crossover, mutation and replacement.
- Transfer the best GA solutions to PSO.
- Refine the candidate strategies using personal-best and global-best learning.
- Select the final strategy satisfying the optimization objectives.
- Report recommended crop combination, predicted yield, expected profit and irrigation-water requirement.

RESULTS AND DISCUSSION

The consolidated framework produces a decision-support pipeline in which prediction and optimization are connected. The Deep Learning stage supplies predicted crop-performance and economic information to the optimization stages. GA provides broad exploration of possible seasonal crop combinations, while PSO provides a refinement mechanism for the best solutions obtained from GA. The framework is designed to evaluate three principal agricultural objectives: maximizing crop yield, maximizing economic profit and minimizing irrigation-water requirement. This makes the method suitable for situations in which a farmer or planner must balance production and economic outcomes with water conservation. The proposed architecture also supports adaptability. Soil characteristics, climatic conditions, crop types, fertilizer levels and irrigation practices can be modified according to the target agricultural region. The modular structure allows the prediction and optimization components to be updated independently when additional data become available. Importantly, the present consolidated manuscript describes the NESO methodology and decision-support framework. Exact numerical performance values, comparative experiments and statistical significance should be reported only after the final experimental runs are completed. This avoids presenting unverified numerical results.

Advantages of the Proposed Neso Framework

- Integrated prediction and optimization: Deep Learning, GA and PSO are combined in a single workflow.
- Nonlinear prediction: Deep Learning can model complex relationships among soil, climate and crop-management variables.
- Large search capability: GA can explore a broad space of seasonal crop combinations.
- Solution refinement: PSO refines promising GA solutions using cooperative swarm intelligence.
- Multi-objective planning: yield, profit and irrigation-water use are considered together.
- Water-aware crop planning: irrigation requirement is explicitly included in the optimization objective.
- Adaptability: the framework can be applied to different seasons, soils, climatic conditions and irrigation settings.
- Decision support: the final output is presented as a practical crop-planning recommendation.

Limitations and Future Work

The quality of the final recommendations depends on the quality, representativeness and completeness of the agricultural data used for training and optimization. Further validation using larger real-world datasets and field-level observations is required before deployment as an operational farm decision-support system. Future work will focus on validating NESO using multi-season and multi-location agricultural datasets, comparing NESO with individual DL, GA and PSO approaches using common evaluation metrics, incorporating additional water and soil constraints, and developing a practical farmer-oriented decision-support interface.

CONCLUSION

This paper presents the Neuro-EvoSwarm Optimizer (NESO), a hybrid Deep Learning–Genetic Algorithm–Particle Swarm Optimization framework for seasonal multi cropping strategy optimization under drip irrigation. The framework integrates agricultural data preprocessing, prediction, evolutionary search and swarm-based refinement. Deep Learning estimates crop yield and economic profit, GA explores candidate seasonal crop combinations, and PSO refines the best solutions. By jointly considering crop productivity, economic profitability and irrigation-water requirement, NESO provides a structured approach to intelligent agricultural planning. The modular architecture makes the framework adaptable to different agricultural environments and suitable for future precision-agriculture applications. Experimental validation with complete numerical results and real-world field data will strengthen the practical evidence for the proposed model.

ABSTRACT

Primary school educators are disproportionately affected by chronic musculoskeletal pain (MSP) and occupational burnout due to prolonged static postures, emotional labour, and limited structured physical activity during working hours. While physiotherapist-led workplace exercise programs (PLWEPs) have demonstrated efficacy in office-based populations, their utility within the teaching profession remains underexplored. This study aimed to evaluate the impact of a structured 12-month PLWEP on musculoskeletal pain severity and burnout dimensions among primary school teachers in Malaysia. A randomised longitudinal cohort design was employed. One hundred and forty-eight (148) primary school teachers (mean age: 38.4 ± 7.2 years; 71.6% female) from six government schools in Selangor were enrolled. Participants were allocated to either an intervention group (n = 74), receiving three supervised 20-minute PLWEP sessions weekly, or a wait-list control group (n = 74). Outcomes were assessed at baseline, 6 months, and 12 months using the Numeric Pain Rating Scale (NPRS), the Maslach Burnout Inventory (MBI), and the Nordic Musculoskeletal Questionnaire (NMQ). At 12 months, the intervention group demonstrated a clinically and statistically significant reduction in musculoskeletal pain (mean NPRS change: -3.1 ± 0.8 vs. -0.6 ± 0.4 in controls; $p < 0.001$). All three MBI subscales — emotional exhaustion, depersonalisation, and personal accomplishment — improved significantly ($p < 0.01$).

Cervical and lumbar regions showed the greatest symptomatic improvement. Adherence to the intervention averaged 78.3% over the study period. Structured PLWEPs integrated into the school workday are efficacious in reducing chronic musculoskeletal pain and alleviating occupational burnout in primary school teachers. Institutional adoption of such programs is strongly recommended, with implications for educator retention, reduced absenteeism, and improved school performance.

Keywords: musculoskeletal pain, teacher burnout, workplace exercise, physiotherapy, occupational health, longitudinal study, India

INTRODUCTION

Teaching is widely recognised as one of the most physically and psychologically demanding professions in public service. Despite being anchored in classrooms rather than industrial settings, primary school teachers are subject to an array of occupational health risks that are frequently underappreciated in both clinical practice and public health discourse. Chief among these risks are chronic musculoskeletal pain and occupational burnout — two conditions that, while distinct in aetiology, often co-occur and mutually amplify each other in the teaching workforce. Musculoskeletal disorders (MSDs) represent the most prevalent form of occupational illness globally, accounting for an estimated 1.71 billion cases and constituting a leading cause of disability and productivity loss (World Health Organization, 2021). Within the teaching profession, the physical demands are multifaceted. Teachers spend significant portions of their workday standing on hard surfaces, adopting asymmetric postures during student supervision and whiteboard use, performing repetitive upper-limb movements during marking and writing, and sitting in ergonomically suboptimal configurations during administrative duties. Longitudinal studies have consistently implicated these biomechanical stressors in the development of cervical, lumbar, shoulder, and wrist pain among educators (Cardoso et al., 2011; Bernal et al., 2015).

Occupational burnout, as conceptualised by Maslach and Jackson (1981), encompasses three interrelated dimensions: emotional exhaustion (the depletion of emotional resources from sustained interpersonal demands), depersonalisation (the development of cynical or detached attitudes toward students and colleagues), and reduced personal accomplishment (a diminished sense of professional efficacy). The prevalence of burnout among teachers has risen markedly in the post-pandemic landscape, driven by expanded administrative workloads, digital learning demands, and heightened behavioural challenges in the classroom (Sokal et al., 2020). Research indicates that teachers experiencing moderate-to-severe burnout are three times more likely to report co-occurring musculoskeletal complaints (Honkonen et al., 2006), underscoring the bidirectional relationship between physical and psychological occupational health. Physiotherapist-led workplace exercise programs (PLWEPs) have garnered increasing empirical support as an evidence-based intervention for musculoskeletal pain in sedentary and physically active occupational groups alike. Unlike generic wellness initiatives, PLWEPs are distinguished by their individualized biomechanical assessments, profession-specific exercise prescriptions, progressive loading principles, and real-time feedback from trained clinicians. Several systematic reviews have reported significant pain reductions and functional improvements associated with workplace exercise in office workers, nurses, and manufacturing employees (Proper et al., 2003; van Eerd et al., 2016). However, dedicated evidence within the primary school teaching context remains sparse, and no longitudinal Malaysian study has previously examined this population. The present study was designed to address this evidence gap by evaluating the short- and long-term efficacy of a structured, physiotherapist-supervised workplace exercise program on musculoskeletal pain and occupational burnout among primary school teachers. The study hypothesised that teachers in the intervention group would demonstrate significantly greater reductions in pain severity and burnout dimensions compared to wait-list controls at both 6-month and 12-month follow-up assessments.

METHODOLOGY

Study Design and Ethical Approval: This study employed a parallel-group, randomised, wait-list controlled longitudinal cohort design. Ethical clearance was obtained from the University Malaya Medical Centre Research Ethics Committee (Reference No. MECID.NO: 2023112-10529) and the Malaysian Ministry of Education Research Division. All participants provided written informed consent prior to enrolment. The study was registered with the Australian and New Zealand Clinical Trials Registry (ACTRN12623001147854) and conducted in accordance with the Declaration of Helsinki.

Participants and Sampling

A total of 148 primary school teachers from six government schools across Selangor, Malaysia, were recruited via purposive cluster sampling. Inclusion criteria required participants to be full-time classroom teachers with a minimum of one year of teaching experience, aged between 25 and 55 years, reporting at least mild musculoskeletal discomfort (NPRS ≥ 2) in one or more body regions at baseline, and free from acute musculoskeletal injury or systemic inflammatory conditions that would contraindicate exercise participation. Exclusion criteria included current enrolment in other structured exercise programs, pregnancy, or planned surgical intervention within the study period. Participants were stratified by school and randomly allocated (1:1) to either the intervention group (n = 74) or the wait-list control group (n = 74) using a computer-generated randomisation sequence concealed in sealed envelopes. The wait-list group received the PLWEP only after the 12-month data collection was completed.

Intervention Protocol

The PLWEP was designed collaboratively by three senior physiotherapists with specialisations in occupational health and musculoskeletal rehabilitation. The program was delivered in small groups of 8–12 participants, three times per week, during scheduled non-teaching periods (morning break or after-school hours), with each session lasting approximately 20 minutes. The exercise protocol incorporated four sequential components: (1) a 3-minute cardiovascular warm-up featuring brisk walking and shoulder mobilisation; (2) 7 minutes of targeted cervical, thoracic, and lumbar stabilisation exercises; (3) 7 minutes of upper and lower extremity strengthening using resistance bands; and (4) a 3-minute cool-down incorporating static stretching and diaphragmatic breathing. Exercises were progressively intensified over 4-week cycles based on participant tolerance and pain response, monitored through session-by-session NPRS ratings.

Outcome Measures

The primary outcome was musculoskeletal pain severity, measured using the Numeric Pain Rating Scale (NPRS; 0 = no pain, 10 = worst imaginable pain), a validated and widely used tool in occupational physiotherapy research. The secondary outcomes encompassed occupational burnout (Maslach Burnout Inventory, MBI; three subscales: Emotional Exhaustion, Depersonalisation, Personal Accomplishment) and regional musculoskeletal symptom prevalence (Nordic Musculoskeletal Questionnaire, NMQ). All measures were administered at baseline (T0), 6 months (T1), and 12 months (T2) by blinded research assistants.

Statistical Analysis

Data were analysed using IBM SPSS Statistics Version 27.0. Descriptive statistics characterised baseline demographics and outcome variables. Between-group differences over time were examined using mixed-model repeated measures ANOVA (MMRM), with time and group as fixed factors and participant as a random effect. Effect sizes were calculated as partial eta-squared (η^2p). Statistical significance was set at $\alpha = 0.05$, and all reported p-values are two-tailed. Intention-to-treat analysis was applied with multiple imputation for missing data, assuming data missing at random (MAR).

RESULTS

Participant Characteristics

Of the 148 enrolled participants, 141 completed the 12-month follow-up (intervention: 70; control: 71), yielding a retention rate of 95.3%. Reasons for withdrawal included personal relocation (n = 3), medical leave (n = 2), and voluntary withdrawal (n = 2). The baseline demographic characteristics of both groups were well-matched, with no statistically significant differences in age, sex, years of teaching experience, baseline pain scores, or burnout subscale scores (all $p > 0.05$). Participants were predominantly female (71.6%), with a mean teaching experience of 11.3 ± 5.8 years. The most commonly affected musculoskeletal regions at baseline were the lower back (67.6%), neck (61.5%), and shoulders (52.7%).

Musculoskeletal Pain Outcomes

The intervention group demonstrated progressive and statistically significant reductions in mean NPRS scores across both assessment time points. At 6 months, the intervention group reported a mean NPRS reduction of 1.8 points (95% CI: 1.4–2.2) compared to 0.3 points (95% CI: 0.1–0.5) in the control group. By 12 months, the cumulative reduction in the intervention group was 3.1 ± 0.8 points versus 0.6 ± 0.4 points in controls, representing a statistically significant between-group difference ($F(2, 138) = 47.3$, $p < 0.001$, $\eta^2p = 0.41$). Cervical and lumbar pain showed the greatest absolute reductions, with shoulder and wrist pain also demonstrating clinically meaningful improvement. Significant time-by-group interactions were observed across all three MBI subscales. Emotional exhaustion scores decreased markedly in the intervention group (mean reduction: 8.4 points; $p < 0.001$) relative to controls (1.2 points). Depersonalisation scores declined by 3.7 points in the intervention group versus 0.4 points in controls ($p < 0.01$). Personal accomplishment scores, which are inversely scored, increased by 5.9 points in the intervention group versus 0.9 points in controls ($p < 0.01$), indicating a meaningful recovery of professional self-efficacy. These effects were first detectable at the 6-month assessment and were sustained or amplified at 12 months.

Adherence and Safety

Mean session attendance across the 12-month intervention period was 78.3% (range: 62–94%). No serious adverse events were reported. Minor exercise-related muscle soreness was noted by 18 participants (24.3%) during the first four weeks, all of which resolved without modification to the exercise protocol. Participant feedback collected via post-study questionnaires indicated high levels of satisfaction, with 91% of intervention participants reporting that they would recommend the program to colleagues and 84% intending to continue similar exercises independently.

DISCUSSION

The findings of this longitudinal cohort study provide robust evidence supporting the integration of physiotherapist-led exercise programs into the working lives of primary school educators. The magnitude of pain reduction observed in the intervention group — a 3.1-point decline on the NPRS at 12 months — substantially exceeds the minimal clinically important difference (MCID) of 1.5 points commonly cited in musculoskeletal pain research (Salaffi et al., 2004), affirming the clinical relevance of these outcomes beyond their statistical significance. The profession-specific design of the PLWEP is likely a key contributor to its efficacy. By addressing the biomechanical signature of primary school teaching — including sustained cervical extension during whiteboard use, prolonged lumbar loading during supervision, and repetitive upper limb demand during marking — the intervention targeted the precise musculoskeletal stressors that drive pain in this population. This contrasts with generic workplace wellness programs, which often apply standardised exercise protocols without regard for occupation-specific postural demands. The superior outcomes observed in the present study relative to comparable teacher-focused generic programs (e.g., Cardoso et al., 2011) lend empirical weight to the principle of exercise specificity in occupational physiotherapy.

The significant improvements in all three MBI subscales warrant careful interpretation. Emotional exhaustion, the most debilitating dimension of burnout, showed the greatest absolute improvement in the intervention group. Several plausible mechanisms may account for this. First, exercise-induced endorphin release and modulation of the HPA axis likely attenuated cortisol-mediated emotional depletion (Koltyn, 2002). Second, the structured social context of group exercise sessions may have provided a form of peer solidarity and professional renewal that is difficult to achieve through individual wellness activities. Third, the reduction in physical pain itself — documented robustly in the NPRS outcomes — likely relieved a significant contributor to daily stress and emotional exhaustion, given the well-established bidirectional relationship between pain and psychological wellbeing (Honkonen et al., 2006). The improvement in personal accomplishment scores deserves particular attention. This MBI subscale captures a teacher's sense of professional competence and impact — a dimension that is rarely targeted by conventional occupational health interventions. The PLWEP may have enhanced personal accomplishment through the accumulation of small, verifiable physical achievements (progressive exercise performance), reinforcing broader self-efficacy beliefs that transferred into the professional domain. This hypothesis is consistent with Bandura's (1977) social cognitive theory, which posits that mastery experiences in one domain can generalise to adjacent domains of functioning. The 78.3% mean adherence rate observed in this study compares favourably with adherence benchmarks reported in workplace exercise literature, which typically range from 60 to 75% (Proper et al., 2003). The supervision by qualified physiotherapists, the scheduling of sessions during designated non-teaching breaks, and the progressive nature of the program — which minimised early-stage injury risk and frustration — are likely explanatory factors. The high rates of post-study satisfaction and intent to continue exercising independently suggest that the program successfully cultivated intrinsic motivation for physical activity, a finding with meaningful implications for long-term behaviour change.

Limitations

Several limitations of the present study merit acknowledgement. First, the absence of participant and assessor blinding is an inherent limitation of exercise intervention trials, introducing the possibility of performance and detection bias. Second, the reliance on self-reported pain and burnout measures, while standard in this field, is subject to social desirability effects. Third, the study was conducted exclusively in government primary schools in Selangor, which may limit the generalisability of findings to private, rural, or international school educators. Fourth, the long-term durability of intervention effects beyond the 12-month study period was not examined, and future research with extended follow-up is warranted. Finally, the heterogeneity in teaching styles, class sizes, and school resources across participating schools introduces unmeasured contextual variability.

CONCLUSION

This 12-month longitudinal cohort study provides compelling evidence that structured physiotherapist-led workplace exercise programs represent a viable, clinically meaningful, and institutionally feasible intervention for reducing chronic musculoskeletal pain and alleviating occupational burnout in primary school educators. The profession-specific design of the PLWEP, its integration into the school workday, and the supervisory expertise of registered physiotherapists collectively account for outcomes that substantially exceed those achievable through generic wellness initiatives. From a public health perspective, the co-benefits of reduced absenteeism, enhanced educator retention, and improved psychological wellbeing suggest that institutional investment in PLWEPs for teaching staff yields returns that extend well beyond the individual participant. School administrators, Ministries of Education, and occupational health policymakers are urged to consider the systematic integration of professionally supervised exercise programs into teacher welfare frameworks, particularly given the elevated occupational health burden documented in this and prior studies. Future research should examine the cost-effectiveness of PLWEPs relative to existing teacher welfare expenditure, explore digital or hybrid delivery models to expand program reach in rural and under-resourced schools, and investigate whether program effects are modifiable by teacher age, subject specialisation, class size, or pre-existing health status. Longitudinal follow-up beyond 12 months would further illuminate the durability of the observed improvements and inform optimal program maintenance strategies.

ABSTRACT

The purpose of this study is to identify the disease that affected the lemon plant's leaf. The majority of us are unable to manually identify the illness in its early stages. For plants to grow disease-free, automatic disease detection is crucial. Growing lemons makes a substantial contribution to the global agricultural economy. However, illnesses like anthracnose, melanose, black spot, citrus canker, citrus greening (HLB), and leaf miner infestations significantly lower fruit quality and yield. In addition to recommending pesticides to treat the sick leaf, our research on lemon leaf disease detection aids in the automatic diagnosis of the disease. For better training and accurate computation, our study uses Convolutional Neural Networks (CNNs), Edge Artificial Intelligence (Edge AI), the Internet of Things (IoT), image processing, and deep learning, especially CNNs. Edge AI reduces latency, bandwidth consumption, and dependence on continuous internet connectivity by performing inference locally on embedded devices. This review summarises recent developments in Edge AI-powered IoT frameworks for citrus leaf disease detection and covers datasets, CNN architectures, image processing techniques, hardware platforms, communication technologies, deployment challenges, and future research directions for smart farming applications. Recent studies also emphasise quantisation, pruning, MobileNet, EfficientNet, and lightweight CNNs for practical edge deployment.

Keywords: Edge AI, Internet of Things, Lemon Leaf Disease Detection, Image Processing, Deep Learning, CNN, Smart Farming, Precision Agriculture

INTRODUCTION

The main problem in agriculture is plant diseases. It impedes the growth of the plant and has other negative effects. The unassisted eye cannot see the illnesses in the leaf. Thus, the development of the agricultural industry requires this type of technology. Farmers are greatly impacted by plant diseases, thus our application aids in the reduction of the disease and the prompt discovery of a cure. Historically, the diagnosis of plant diseases has relied on manual observation and expert opinion, both of which are subjective and inefficient for large-scale surveillance. The advancement of artificial intelligence (AI), particularly image-based techniques, has made automated disease diagnosis a viable and scalable strategy. Plant diseases can be recognised and classified from leaf images using AI methods such as machine learning (ML), deep learning (DL), and, more recently, sophisticated architectures like convolutional neural networks (CNNs) and transfer learning. The goal of this study is to give a thorough overview of the most recent AI-based methods that are especially used to identify lemon leaf disease. The evolution of AI in this field, the datasets used, preprocessing methods, model designs, performance evaluation criteria, and real-world deployment scenarios are all covered in this study. This paper identifies future research directions for improving model accuracy, robustness, and field application by assessing current trends and challenges.

Lemon Leaf Diseases

Many biotic stressors can affect lemon trees, the majority of which are brought on by bacteria, fungi, and viruses that start on the leaves and spread to other areas of the plant. Since the condition of the leaves directly affects the plant's capacity to carry out photosynthesis and sustain yield, early detection of these signs is essential. The following is a quick description of the most prevalent illnesses brought on by lemon leaves: One of the most common bacterial illnesses that harm lemon plants is Citrus Canker, which is brought on by Xanthomonas citri subsp. citri. The disease is defined by raised, corky lesions surrounded by yellow halos on leaves, stems, and fruits. The early fall of infected leaves may reduce the tree's capacity to photosynthesise and bear fruit as the disease progresses. Citrus canker spreads rapidly through wind-driven rain, polluted equipment, and contaminated planting materials, making early detection essential for effective disease management. Another particularly destructive disease is Citrus Greening, also known as Huanglongbing (HLB). It is caused by the bacterium Candidatus Liberibacter spp. and is carried by the Asian citrus psyllid (Diaphorina citri). Deformed fruits, a bitter taste, decreased tree growth, vein yellowing, and blotchy yellow leaf mottling are all symptoms of this disease. Since there is currently no effective treatment, the primary management strategies to control the spread of HLB include early discovery and the removal of sick trees..

Citrus Canker

Citrus canker is caused by the bacteria Xanthomonas axonopodis pv. citri. It initially appears as water-soaked sores on leaves, which eventually turn brown with yellow halos. The lesions may come together to cause twig dieback and leaf drop. Since it spreads swiftly by wind, rain, and contaminated instruments, early detection is crucial for containment.

Greasy Spot

caused by the fungus Greasy spots are little, oil-like, yellowish-brown areas on the underside of leaves caused by Mycosphaerella citri. These lesions gradually form and darken, leading to early defoliation. It can drastically lower fruit yield and is especially prevalent in humid areas.

Melanose

Melanose, which appears as small, raised, dark brown to black dots that may form rough patches, is caused by the fungus Diaporthe citri. It usually occurs in older trees with poor ventilation. It is typically not fatal, but it reduces the financial value and aesthetic appeal of the fruit and plant.

Sooty Mold

A secondary fungal growth on the honeydew secretions of sap-sucking insects including mealybugs, whiteflies, and aphids is known as sooty mould. It is not a disease unto itself. Plant vigour and productivity are indirectly impacted by the dark covering's reduction of photosynthesis.

Leaf Miner Infestation (Mimics Disease Symptoms)

Leaf miner larvae create serpentine patterns inside young leaves that resemble fungal infections, although they are not a disease. To prevent misdiagnosis, accurate AI models must be able to differentiate between many non-disease indications. Image-based AI classification is feasible since various diseases have distinct visual manifestations in terms of colour, shape, and texture. However, conventional models can have trouble differentiating between similar-looking leaf damage because of co-infections and environmental overlaps. This emphasises how crucial sophisticated AI models trained on carefully selected datasets with significant inter-class variation are.

LITERATURE REVIEW

A literature survey is a comprehensive summary of all the significant research and publications related to a certain topic or field of study. By summarising prior research, methods, and findings, a literature review aims to provide future research with a solid foundation. It helps researchers avoid duplication, refine their research ideas, and build upon previous findings to offer new insights. Gittaly Dhingra et al. (2017) [1] discussed the use of computer vision technologies in agriculture to identify and categorise plant leaf diseases. The relationship between illness symptoms and their effect on product yield is the subject of this research. In order to achieve greater accuracy, it also deals with increasing the quantity of training data and testing. Vijai Singhet al.(2017) [2], presented a technique for segmenting photos of plant leaves. A technique for identifying and segmenting photographs was proposed by the author. Initially, a variety of devices were used to record different types of images, which were then processed using different segmentation approaches. The author's m*n image contains R, G, B components in every pixel. To extract features, the colour co-occurrence method was used. The tests stated above are conducted using MATLAB. The author only displays the data for beans, leaves, lemons, and banana leaves. Further research is needed for all types of leaves. Mohammed Brahim et al.(2017) [3] presented a deep learning approach in 2017 to develop a classifier for early disease identification and classification using deep learning models. Additionally, the occlusion concept was put forth to better understand the disease and localise its affected areas. In order to reduce the computation and size of deep models for small machines, such as mobile phones, more study is required. The author uses datasets that have been published in Good Fellow, Bengio, etc.

Wajid et al. (2018) [4], conducted research in 2018 on the effectiveness and appropriateness of several classification techniques, such as Naïve Bayes, ANN, and decision trees. The results of these three algorithms are compared, and it has been discovered that the decision tree classification method for orange situations is more effective than ANN and naive-based methods. The following five sequential processes are typically included in the execution of the Citrus fruit identification and classification algorithm: database, data augmentation, dataset pre-processing, feature extraction, identification, and classification. Kukreja and Dhiman et al.(2020) [5], introduced a trustworthy CNN system to identify apparent citrus fruit problems. A dense model that does not employ pre-processing or data augmentation approaches is compared to the suggested method. The suggested model has an accuracy rate of 89.1%. The findings demonstrate that data augmentation and preprocessing methods have yielded precise estimations of citrus crop damage. H. Singh, R. Raniet al. (2020) [6], used K-Nearest Neighbours, Multi-Layer Perceptrons, Support Vector Machines, and Linear Discriminant Analysis to identify citrus leaf diseases in 2020. Following the division of sick leaf sections using the k-means clustering method, colour and textural features were collected. The most relevant features are identified using the ANOVA F-test. In the end, the pathogens were identified using the previously indicated methods. There were 236 contaminated citrus leaves in the study. Combining texture and colour features improved precision. For colour and texture features, the precision of LDA, MLP, KNN, and SVM was 84.32 percent, 81.36 percent, 77.12 percent, and 80.93 percent, respectively.

Solanki and Bhandari et al. (2022)[7], Thirty percent of the 609 lemon leaf images in the Mendeley dataset were utilised for testing, while the remaining seventy percent were used for training. Experiments showed that the ResNet model performed better than the other models, with a classification accuracy of 97.66%. The proposed approach demonstrates how deep learning may effectively improve the early detection and classification of lemon leaf disease, improving precision farming and reducing crop losses. V. Balafas, E. Karantoumanis et al. (2023) [8], reviews AI-driven plant disease detection techniques that make use of computer vision, deep learning, and transfer learning. It highlights CNN architectures, explainable AI, UAV-based imaging, and IOT integration while pointing up problems such dataset scarcity and field generalisation. D. S. Joseph, P. M. Pawar et al. (2024) [9], offer a hybrid architecture for multi-class plant disease classification that integrates Local Binary Pattern texture descriptors with deep CNN features. By boosting discriminative power and robustness, feature fusion outperforms solo CNN or manually developed feature-based methods in terms of accuracy.

A. Bhargava, A. Shukla et al. (2024) [10], provides a comprehensive comparison of deep learning and machine learning models for the classification and identification of plant diseases. It demonstrates the advantages of CNN-based and object recognition frameworks over traditional ML techniques, including transfer learning, GAN augmentation, and hyperspectral imaging for precision agriculture. Mundla Rama Mohan Reddy et al. (2025) [11], offered a comprehensive examination of AI-based techniques for detecting and classifying lemon leaf illnesses. The study shown that deep learning models—more especially, CNNs and transfer learning techniques—significantly improve sickness diagnosis accuracy when compared to traditional manual inspection methods. For future smart agricultural applications, the authors recommended Edge AI, IoT connectivity, Explainable AI, and lightweight models. However, they also highlighted problems including small datasets, inadequate field generalisation, and computational complexity. Anusha B. M., Harshitha et al. (2026) [12], suggested a real-time lemon leaf disease detection system using image processing and Convolutional Neural Networks (CNN) on a Raspberry Pi platform. The system captures live leaf pictures, preprocesses them using Open CV, and classifies ailments using a Tensor Flow Lite model. It accurately detects illnesses like anthracnose, citrus canker, leaf curl virus, and spider mite infestation and offers treatment recommendations through an intuitive interface. The proposed solution reduces the usage of pesticides, enables early disease identification, and encourages intelligent and sustainable precision agriculture.

Challenges

Although automated lemon leaf disease diagnosis has significantly risen thanks to Edge AI, IoT, image processing, and deep learning, a number of barriers limit its widespread application in actual agriculture. Some of the primary issues include the lack of high-quality disease datasets, changing environmental conditions, the similarity of disease symptoms, and edge devices' processing constraints. Additional problems including energy consumption, erratic wireless connectivity, high implementation costs, cybersecurity risks, a lack of model explainability, and IoT device compatibility further affect system performance and scalability. To enable reliable, economical, and sustainable smart farming solutions, future research should concentrate on creating lightweight and explainable AI models, growing field-based datasets, enhancing energy-efficient edge computing, improving secure communication, and validating systems under actual orchard conditions.

Research Gap

There are still a number of research gaps in the creation of intelligent systems for diagnosing lemon leaf disease, despite notable developments in image processing, deep learning, Edge AI, and IoT-based plant disease detection. There aren't many large, varied, and publically accessible datasets because the majority of recent research focuses on databases of citrus illnesses or general plants rather than diseases exclusive to lemon trees. Furthermore, a lot of suggested methods rely on cloud computing, which raises latency, uses more bandwidth, and necessitates consistent internet access. Few studies combine deep learning, IoT sensors, and Edge AI into a cohesive framework that can diagnose diseases in the field in real time. Additionally, lightweight deep learning models appropriate for edge devices with low resources have not been thoroughly investigated, and there are currently few multimodal techniques that combine ambient sensor data with leaf images. It is challenging to evaluate the practical applicability of current technologies due to the absence of comprehensive field validation in a variety of environmental situations.

Thus, a significant research opportunity in smart farming is creating an effective, real-time, Edge AI-powered IoT system for precise lemon leaf disease diagnostics using optimised CNN models and multimodal data.

Future Research Directions

Lemon leaf disease detection is changing because to the quick development of computing and Internet of Things technology, however there are still issues with accuracy, scalability, and practicality. Large, varied datasets from commercial orchards should be the main focus of future research, together with the development of lightweight neural networks tailored for edge devices. Farmer trust and diagnostic reliability will be improved by hybrid models that combine CNNs and Transformers, multimodal sensor fusion, and explainable techniques. Methods like digital twins, autonomous UAVs, and federated learning present intriguing avenues for automated, predictive, and cooperative disease management. Precision agriculture will eventually be able to increase productivity and resilience, but sustainable adoption will depend on energy efficiency, cybersecurity, and large-scale field testing.

CONCLUSION

In smart farming, edge AI combined with IoT offers a practical way to identify lemon leaf disease in real time. It is possible to diagnose diseases quickly and accurately without continuous cloud access by integrating image processing, wireless connectivity, embedded edge hardware, and lightweight CNN models. This system uses CNN with numerous algorithms to attain great accuracy. Once a disease is identified, a remedy is found. We created the system so that everyone may have access to wholesome plants and live contented, joyful lives. We intend to add more features in the future, such the ability to use CCTV to watch the entire growing area in order to discover infections.

ABSTRACT

The stability of centrality measures is an important issue in network analysis, especially when a network changes because of failures, attacks, or noise. Although centrality measures have been widely studied in unsigned networks, less attention has been given to their behavior in signed weighted networks. In this study, we analyze the impact of various forms of perturbations to the network on the centrality values. These perturbation forms are random failure, selective attack, and introduction of noise to the network. We propose a measure for the stability of centrality by calculating the Centrality Stability Index (CSI). Analytical bounds are derived using a Lipschitz continuity assumption on centrality mappings, establishing a relationship between perturbation magnitude and centrality variation. Furthermore, we show that negative interactions amplify instability and accelerate degradation of centrality structure. The theoretical results are supported by Monte Carlo simulations. The simulation results show that the stability of centrality measures gradually decreases as the level of perturbation increases. They also show that negative interactions make signed weighted networks more sensitive to structural changes. Overall, this work provides a useful tool for the analysis of the robustness of centrality measures in signed weighted networks.

Keywords: Complex networks; Signed weighted networks; Centrality measures; Network robustness; Perturbation analysis; Centrality Stability Index; Monte Carlo simulation; Network resilience.

INTRODUCTION

The rapid growth of network-based data has made network analysis an important area of research across many scientific disciplines. From social and biological systems to engineering and communication networks, many real-world problems can be represented as networks in which nodes denote individual entities and edges describe the relationships among them. Exploring the connections makes it possible to determine the structural features of the network and the position of each node within the network. This is why the issue of finding the key players has become one of the core problems of network analysis; for this purpose, centrality measures such as degree centrality, betweeness, and eigenvector centrality are commonly used. While being well-studied, centrality measures were initially introduced for those networks where all relations are non-negative. In reality, however, there are many different systems which consist of both positive and negative relationships. The examples may be social networks with friendship and conflicts, biological networks with activation and inhibition, and economical systems with cooperation and competition. Such networks are more accurately represented as signed weighted networks, where both the sign and the strength of an interaction influence the overall network structure. The inclusion of negative interactions makes the analysis of node importance considerably more challenging because they affect the way influence is distributed throughout the network.

Another important issue is that network structures are rarely fixed. Changes could result due to partial observation, measurement error, failure, or deliberate attack. Changes in the network even in very small scale will change the values of centrality and thus the ranking of influential nodes. Hence, in order for those applications which depend on the centrality measures to make decision, it is essential to know whether such measures are robust to the changes caused by the perturbations in the network. This paper tries to address the above questions by studying the robustness of centrality measures of signed weighted networks against perturbations in several situations. In this work, we propose Centrality Stability Index (CSI) which reflects the changes in node importance after the network is perturbed. A theoretical model is built to describe the relationship between perturbation size and changes in centrality measures. And finally, Monte Carlo simulation experiments are performed to validate the theoretical results.

Mathematical Preliminaries

Let $G = (V, W)$be a signed weighted network, where$V = \{1,2, \dots N\}$is the set of nodes and in $W = [w_{ij}] \in \mathbb{R}^{N \times N}$is the weighted adjacency matrix. Each element w_{ij}describes the relationship between nodesi and j. A positive value represents a positive interaction, while a negative value represents a negative interaction. A centrality measure is a function

$$C: \mathbb{R}^{N \times N} \to \mathbb{R}^{N}$$

which assigns a centrality value to every node in the network. The centrality values of all nodes are written as $C(W) = (C_1, C_2, \dots, C_N)$, where C_i is the centrality value of node i. Together, these values describe the importance of all nodes in the network.

Perturbation Model

To study the effect of perturbations, the original network W is changed to a perturbed networkW', which is given by

$$W' = W + \Delta W$$

Where ΔWrepresents the changes made to the network. The size of the perturbation is measured using the Frobenius norm,

$$\|\Delta W\|_F = \epsilon$$

This approach allows different types of perturbations to be described using the same model. Random failures are represented by randomly removing a small number of connections. Targeted attacks affect the most important nodes in the network, while noise injection changes the edge weights by adding small random variations.

Centrality Stability Index

To quantify the effect of perturbations on centrality, we define the Centrality Stability Index as

$$CSI(W, W') = 1 - \frac{\|C(W) - C(W')\|_1}{\|C(W)\|_1}$$

This measure takes values in the interval [0,1], where values close to one indicate high stability and values close to zero indicate significant deviation.

Theoretical Analysis

To derive analytical insights, we assume that the centrality mapping Csatisfies a Lipschitz condition. That is, there exists a constant $L > 0$ such that

To understand how perturbations affect centrality, we assume that the centrality$C$ function satisfies the Lipschitz condition. This means that there exists a positive constant L such that

$$\|C(W) - C(W')\|_1 \leq L\|W - W'\|_F$$

Using this assumption, the following lower bound for the Centrality Stability Index CSI can be obtained:

$$CSI(W, W') \geq 1 - \frac{L\|\Delta W\|_F}{\|C(W)\|_1}$$

This result shows that the CSI depends on the size of the perturbation. As the perturbation becomes larger, the CSI becomes smaller, indicating a reduction in the stability of the centrality values. Furthermore, Now consider two perturbation levels, $\epsilon_1 < \epsilon_2$. Then, by the monotonicity of the norm, it follows that

$$CSI(\epsilon_1) \geq CSI(\epsilon_2),$$

which means that increasing the perturbation does not increase the stability of the centrality values.

To study the effect of positive and negative interactions, the adjacency matrix is written as

$$W = W^+ - W^-,$$

whereW^+ and W^-represent the positive and negative parts of the network, respectively. Negative interactions lead to increased variability in the centrality values of the network. As a result, signed weighted networks are generally less stable than networks with only positive interactions. Finally, we observe that there exists a critical perturbation threshold $\epsilon_c$such that centrality values undergo a sudden collapse. Formally, The analysis also suggests that there is a critical perturbation level, denoted by ϵ_c, beyond which the centrality values change rapidly. This can be represented as

$$\lim_{\epsilon \to \epsilon_c^-} CSI > 0, \text{ while } \lim_{\epsilon \to \epsilon_c^+} CSI \approx 0.$$

From this equation, it is shown that the network is quite stable for some level of perturbations; however, beyond that level, there is a sudden drop in the stability of the network.

Simulation Methodology

The simulation was carried out in four steps. First, a signed weighted network was generated and the centrality value of each node was calculated. The network was then modified using different perturbation methods, and the changes in node importance were measured using the Centrality Stability Index CSI. The same procedure was repeated several times, and the average of all simulation results was taken for the final analysis.

Network Generation

The procedure starts with creating synthetic signed weighted graphs through random graph creation approach. In case of having a graph that has N nodes, the probability of existence of edge between each two nodes will be p. This is the parameter that determines the density of connections in the graph. Each edge will be assigned a weight randomly selected from a normal distribution. Lastly, the signs of each edge will be determined with sign ratio of r.

The network parameters used in the simulation are summarized in Table 1.

Centrality Computation

The next step after creating the network is determining the centrality measure for each node to derive the base centrality vector. Eigenvector centrality is the measure employed in this study as it takes into account the influences

derived from the node's direct and indirect connections. However, the proposed framework can also be applied to other centrality measures.

Perturbation Models

To study the robustness of the network, three different types of perturbations are considered.

Random Failure: A fraction of the edges is removed at random from the network. These are some of the random faults that happen during the working of a network.

Targeted Attack: The nodes having the maximum centrality values will be removed. This is considered to be an attack that targets the most critical nodes in the network.

Noise Injection: The edge weights are perturbed by small Gaussian noise. This affects the intensity of connection but not the topology of the network, which is represented as

$$w'_{ij} = w_{ij} + \epsilon_{ij}, \epsilon_{ij} \sim \mathcal{N}(0, \sigma^2)$$

The perturbation parameters are summarized in Table 2.

Centrality Stability Evaluation

After perturbation, the centrality measures are recalculated to get (C(W')). The difference between the centrality values before and after the perturbation is calculated through Centrality Stability Index (CSI):

$$CSI(W, W') = 1 - \frac{\|C(W) - C(W')\|_1}{\|C(W)\|_1}$$

CSI will tell us about the amount of change in the centrality measures after perturbation. If the CSI is near 1, then the centrality values do not change much, which shows that the network is stable. On the other hand, if the CSI value is near 0, then the network is not stable.

Monte Carlo Procedure

The simulation is repeated several times for each set of network parameters and perturbation levels. In each run, a signed weighted network is first generated, and the centrality values are calculated. A perturbation is then applied to the network, after which the centrality values are calculated again. The Centrality Stability Index (CSI) is computed by comparing the centrality values before and after the perturbation. The same procedure is repeated for 500 independent runs, and the average CSI value is used for the final analysis. In such a manner, repeating the simulation will help minimize the impact of randomness.

Implementation Details

The simulations were performed via Python and its scientific computing libraries. This set of software was used to generate the signed weighted networks, implement various perturbation techniques, and compute the centralities. Every simulation was done multiple times, and the mean value of all repetitions was calculated as the final result. In this way, the impact of randomness was minimized.

Connection to Theoretical Results

The simulation results were analyzed by making comparisons between CSI values for various perturbation levels. As the perturbation level increased, the CSI value decreased progressively. This shows that the stability of the centrality measures becomes lower as the network undergoes more changes. For lower levels of perturbation, the reduction in CSI was almost linear. This agrees with the theoretical analysis, which suggests that small changes in the network produce small changes in the centrality values. Conversely, with an increasing perturbation, the CSI decreased at a much faster rate, meaning that the network was more vulnerable to the changes in its structure. From the results, it was also clear that networks containing a higher number of negative edges destabilized faster than the networks having a lower number of negative edges. This implies that the presence of negative interactions increases the sensitivity of the centrality measures to any perturbation. In some cases, the value of the CSI fell sharply at a certain threshold value of perturbation. This implies that when exceeding a certain point, even a small increment in the perturbation value would result in a significant change in the centrality measure.

RESULTS AND DISCUSSION

The findings from the Monte Carlo simulations have been used for investigating the behavior of the centrality measures under different kinds of perturbations. For the same purpose, CSI has been estimated under different perturbation rates to investigate the stability of the node significance. A representative set of results illustrating the behavior of CSI under increasing perturbation levels is presented in Table 3. Table 3.Average Centrality Stability Index (CSI) for different perturbation methods based on 500 Monte Carlo simulation runs. Values are reported as mean ± standard deviation. Higher CSI values indicate better stability of the centrality measure values.

DISCUSSION

The simulation results show that the stability of centrality measures decreases as the level of network perturbation increases. In all three perturbation models, the Centrality Stability Index (CSI) became smaller as the network experienced more structural changes. It shows that the importance of a node gets less stable in case there is some perturbation in the network. From all the perturbation techniques, targeted attacks were most effective in destabilizing the network. It was observed that removal of a few significant nodes brought about a reduction in CSI even at low perturbation values. When they are removed, the importance of many other nodes also changes, making the network less stable. Random failures affected the network in a different way. Since nodes or edges were removed without considering their importance, the changes in CSI were more gradual. The network was able to retain much of its original structure, and the decrease in stability was slower than that observed for targeted attacks. The effect of noise injection was smaller than the other two perturbation methods. Since the weights were modified due to the introduction of noise, there was no change in the network structure. Therefore the CSI values did not decrease significantly, which means that moderate modifications in the edge weights are less effective in altering centrality than the deletion of important vertices or edges. Both theoretical and simulation results supported each other. In either case, the greater the perturbation rate, the lower the centrality stability. This means that Centrality Stability Index can be used to analyze the changes in centrality when signed weighted networks undergo various perturbations. In particular, these results demonstrate the importance of protecting important nodes.

CONCLUSION

In this study, the changes in centrality metrics in the face of random failures, targeted attacks, and noise in the network have been studied for the case of signed weighted networks. To measure these changes, we introduced the Centrality Stability Index (CSI), which compares the importance of nodes before and after the network is disturbed.
Our theoretical analysis showed that larger changes in the network lead to larger changes in centrality values. Among the different perturbations considered, targeted attacks had the greatest effect on the stability of the network. We also observed that networks with more negative interactions were more sensitive to structural changes than those with fewer negative interactions. The simulation results supported these observations. As the level of perturbation increased, the stability of the centrality measures gradually decreased. For larger perturbations, the changes in centrality structure happened significantly faster, which proved the high instability of the network. In general, this study has provided an approach that enables the analysis of robustness of centrality measures in signed weighted networks. The suggested measure of robustness (CSI) allows assessing the stability of centrality measures in case of variations in the network. Future research should focus on extending this idea to dynamic networks and other centrality measures.

ABSTRACT

L-asparagine ad mixture with Ammonium Acetate (LAASC) using sodium chloride solution as solvent was carried out by taking L-asparagine and Ammonium Acetate in the molar ratio 2:1 and sodium chloride solution(1mol%) as solvent. To study the effect of solvent environments on crystal quality and physical properties, a 1 mol% NaCl solution was used as the solvent in a slow evaporation solution growth method. Powder X-ray diffraction (PXRD) analysis, which displayed distinct and sharp peaks, confirmed the structural integrity of the synthesized crystals. Fourier Transform Infrared (FTIR) spectroscopy was employed to identify the intrinsic functional groups of L-asparagine. The optical properties were examined using UV-visible spectroscopy. Mechanical hardness was determined from the hardness number obtained through mechanical testing. Nonlinear optical (NLO) materials exhibit exceptionally high optical nonlinearity in their single-crystal form, making them highly valuable for applications such as optical data storage, information processing, and telecommunications. The synthesis of novel NLO materials with unique properties, along side the growth of superior single crystals, is therefore of great interest for these advanced applications. L-as paragine, an amino acid, is known to be present in organic NLO compounds.

Keywords: PXRD, FTIR, UV-VIS, Hardness, NLO and dielectric.

INTRODUCTION

The electronics industry has greatly benefited from advances in crystal growth, both by refining existing methods and developing new ones. High-quality, defect-free crystals are essential for practical devices as well as fundamental

research. L-asparagine crystals have potential applications as second harmonic generators in sophisticated laser-based imaging, communication, data storage, and countermeasure systems [1–5]. NLO crystals are particularly valuable in laser frequency conversion. The choice of crystal growth method depends largely on the material's properties and desired crystal size. Amino acids, including L-asparagine, exhibit unique features like nonlinear optical (NLO) behavior [2–9]. They have also been used in the development of UV-transparent borate crystals [10–15]. Solvent-assisted growth is an effective approach for tuning crystal properties, as the solvent selection can significantly impact nucleation rate, crystal morphology, size, and internal defects. The slow evaporation solution growth method is widely employed for producing organic single crystals due to its simplicity, cost-effectiveness, and ability to yield high-quality crystals under ambient conditions. However, despite L-asparagine's known properties, systematic studies investigating the influence of different solvents on its physical and functional characteristics remain limited.

Experimental

In this study, L-asparagine was recrystallized and used as the starting material. and sodium chloride were procured from Hi-Media, India. The synthesis of LAASC was carried out by mixing L-asparagine and Ammonium Acetate(2:1) and a 1 mol% sodium chloride solution as the solvent. The solution of synthesis LAASC salt was separately stirred for approximately two hours and then filtered. Crystal growth was subsequently achieved using the slow evaporation method After the recrystallization process, more transparent crystals were obtained. All the crystals exhibited morphologies different from those of the pure crystals. The growth duration and sizes of crystal is summarized in Table 1. Crystals with fewer imperfections were selected for various characterization studies.

Powder X-ray diffraction (PXRD) studies

After the recrystallization process, more transparent crystals were obtained. All the crystals exhibited morphologies different from those of the pure crystals. The growth duration and sizes of two types of crystals are summarized in Table 1. Crystals with fewer imperfections were selected for various characterization studies.

Fourier Transform of Infrared (FTIR) Spectroscopy

FTIR spectroscopy was employed to identify the functional groups present in the synthesized organic materials. This technique provides valuable information regarding the functional groups, chemical bonds, and molecular structure of the crystals. The FTIR spectra, shown in Figure 2 , were recorded using a SHIMADZU-F spectrometer with KBr pellet technique in the wave number range of 400–4000 cm^{-1}. In FTIR analysis, each functional group exhibits characteristic absorption bands at specific frequencies, enabling qualitative identification of the molecular constituents and confirmation of crystal formation.

Uv-Visible Spectroscopy Analysis

The transmission spectra of pure L-asparagine and its based single crystal were recorded using a PerkinElmer Lambda 35 UV–Visible spectrometer in the wavelength range of 190–1200 nm, and the corresponding spectra are presented in Figure 4. The observed optical transparency window extends from 200 to 900 nm, indicating high transparency in both the visible and near-ultraviolet regions. This wide transparency range suggests that the grown crystal is suitable for optical applications requiring minimal absorption in these spectral regions.

Mechanical Studies

Here is a polished and academically refined version of your paragraph with improved grammar, clarity, and scientific tone: Micro hardness is an important parameter for evaluating the mechanical strength and quality of grown crystals [14]. It serves as an indicator of the material's resistance to deformation and provides insight into its elastic and plastic behavior. The hardness of a material depends on several factors such as interatomic spacing, lattice energy, and the heat of formation. Micro hardness measurements of pure L-asparagine and its based crystal was carried out using a Leitz micro hardness tester equipped with a pyramidal diamond indenter. The crystals were carefully mounted, and loads ranging from 25 to 100 g were applied on the selected crystal faces. Each indentation was maintained for a dwell time of 10 seconds. The diagonals of the indentation were measured using a calibrated

micrometer attached to an optical microscope with a Vickers diamond indenter. The Vickers hardness number (H_V) for differ rent applied loads was calculated using the relation:

$$H_V = 1.8544\ P/d^2$$

where P is the applied load in kilograms, d is the diagonal length of the indentation in millimeters, and 1.8544 is a constant. Figure 5 shows the variation of the Vickers micro hardness number (H_V) as a function of the applied load. The data show that H_V rises with P, which is explained by the reverse indentation size effect. This increase in the sample's hardness value indicates that an impurity has been incorporated into the L-asparagine crystal's lattice. Estimation of Work Hardening Coefficient (n): The log P vs log d plot in Figures 6 can be used to estimate the work hardening coefficient. The work hardening coefficient (n) for each formed crystal is determined from figure 6 using the least squares fit approach; the result is shown in Table 2. It is linear, and the work hardening coefficient (n) is determined by its slope. The values of the work hardening coefficient (n) for the grown crystal is presented in Table 2. According to Onitsch and Hanneman, materials with n values greater than 1.6 are classified as soft materials. In the present investigation, all the synthesized crystal exhibits n values exceeding 1.6, indicating their soft nature. This soft mechanical behavior suggests that the grown crystals can be easily processed and are well suited for device fabrication and practical technological applications Energy Dispersive Analysis by X-ray (EDAX) is used to confirm the composition of components Na, Cl, C, N, and O in L-asparagine based crystals. The EDAX spectra of LAASC crystals are displayed in Fig. 20. It is possible to estimate percentage of certain elements from the spectra. It was evident that admixtured elements like Na and Cl are present in the corresponding crystals since Table 9 provides the composition of all the elements and the percentage of elements present in eachcompound

SUMMARY AND CONCLUSION

Using a 2:1 ratio of L-asparagine to Ammonium Acetate, analar reagent grade (AR) L-asparagine-based crystals, such as L-asparagine admixture with Ammonium Acetate (LAASC), were made using sodium chloride solution as a solvent (1 mol%). LAASC crystal is grown using the sJow evaporation process. A more translucent crystal may result from the recrystallization process. The generated crystals are subjected to a range of characterization techniques such as FTIR analysis, UV-visible spectrophotometer, X-ray diffraction and micro hardness tests. From the powder XRD patterns as a result of doping , slight variation of intensity of based samples as compared to L-Asparagine and the most prominent peaks with maximum intensity of the XRD patterns are different. The different functional groups from the band assignment for the produced crystals are revealed by FTIR analysis. The UV-visible spectrum analysis reveals the transparency of LAASC crystal. The band gap values for LAASC crystals are slightly larger than that of pure L-asparagine. Specifically, the energy gap value is 6.33 eV for LAASC. Correspondingly, its cut-off wavelength is 196 nm respectively. The hardness number increases with the applied load. All the crystals formed in this study have work hardening coefficients (n) greater than 1.6, classifying them as soft materials.

ABSTRACT

The measurement of scientific productivity is regarded as a key indicator for assessing the impact of research on the scientific community. This study presents a scientometric analysis of the publication output of State Universities in Tamil Nadu. The data were collected from the Web of Science database for the period from 2005 to 2024. A total of 42,999 publications were identified in the database. The study analyses the publication output of State Universities in Tamil Nadu using both qualitative and quantitative methods. The results show that, among the universities, the University of Madras (UNOM) recorded the highest overall publication output, with 7,602 publications, securing the first rank. The analysis reveals that journal articles constitute the dominant form of scholarly communication. India emerged as the most preferred country for research collaboration, accounting for 42,999 publications, which represents almost the entire publication output of the State Universities. The consistent increase in publication output reflects the growing research activities and scholarly contributions of State Universities in Tamil Nadu. Overall, the time-series analysis confirms an upward growth trend in research productivity from 2005 to 2024.The study examines the research output of the universities, source-wise publication patterns, Relative Growth Rate (RGR) and Doubling Time, geographical distribution of research, citation impact, and trends in scientific productivity over the study period. The study aims to assess the research performance of State Universities in Tamil Nadu, identify their areas of strength and weakness, and provide insights into their academic and research excellence.

Keywords: Scientometric, Research Productivity, Web of Science, Authorship pattern, Annual Growth Rate, Time-Series Analysis and Country

INTRODUCTION

Universities, in general, focus on research-oriented publications and related activities. It is a well-established fact that universities around the world have played a significant role in driving the productivity of research and research manpower. The research potential and productivity of an institution largely determine its development, influence, and capacity to create and distribute wealth. The measurement of research productivity is based on several variables. Three dominant variables include registered, ongoing, and completed research projects. Another widely used measure for analyzing research productivity is publication output. The measurement of research performance has become a routine, periodical affair in most developed countries. Until a few years ago, the criteria for such measurements remained a subject of debate, although various scales were under trial. Today, measuring the research performance of universities using scientometric and bibliometric principles has become an accepted practice, despite some criticism from certain academic circles. Peer-reviewed research publications and their impact factors are considered, along with various socio-psychological factors influencing research performance and productivity. Publication counts are widely used to assess research productivity by individuals, organizations, and even countries. This study investigates the research performance of traditional academic universities in Tamil Nadu, focusing on the analysis of publication output as its primary measure. Being the first study of its kind at the institutional level in this region, this research could serve as a starting point for measuring research productivity performance in universities across Tamil Nadu. The focus of this research is on the " Publication Output of State Universities in Tamil Nadu: A Scientometric Analysis"

REVIEW OF LITERATURE

Faheem Akbar, Muhammad Arif, and Muhammad Rafiq (2023) have evaluated the research productivity of Pakistan Agricultural Research Council (PARC) researchers from 2001 to 2020 using scientometric indices. It takes of four-phase method that includes data retrieval from Scopus and Web of Science, as well as data merging and analysis with R-Studio and VOSviewer. It introduces an innovative technique for combining WoS and Scopus data in R-Studio, providing insights for agricultural research. Manoj Kumar Verma and Saumen Das (2020)has investigated the scientometric analysis of research publications at Tripura University during a ten-year period (2010-2019), analysing 503 papers indexed in the Web of Science database. The study investigates patterns of publication, annual growth, authorship, document formats, collaboration, and prolific authors. Collaboration was considerable, with Jadavpur University providing 48 papers, or 9.54% of the total. Saumen Das, Sunil Kumar Yadav, and Manoj Kumar Verma (2020) analysed 586 publications from Mizoram University over the course of 17 years (2002-2018). The research focuses on authorship trends, geographical distribution, document categories, and prolific authors. Satish Kumar and Senthil kumar (2019) evaluated the research productivity of the Indian Institute of Science (IISc), Bangalore, India, which was ranked top in the National Institutional Ranking Framework (NIRF) for five years (2014-2018). The study examined 12,130 research papers from the Web of Science database, focusing on year-wise institutional contributions, compound annual growth rate, research areas, collaborating institutions and countries. The data was analysed using a variety of scientometric methodologies, with the goal of successfully evaluating and interpreting the Institute's research production.

Objectives

The researcher has framed the following objectives for the purpose of present research.

- To identify the year wise and source wise distribution of research output of Universities across Tamilnadu.
- To examine the growth rate, doubling time and exponential growth rate of Tamilnadu state Universities research output.
- To examine the Annual Growth Rate (AGR) of Tamil Nadu State Universities Publications
- To analyze the year-wise authorship patterns of research publications produced by state universities in Tamil Nadu.
- To compare and analyze the country-wise research output performance of universities in Tamil Nadu.

METHODOLOGY

This scientometric study analyzes the Publication output of state universities in Tamil Nadu using data from the Web of Science (WoS) database. The study examines publication trends, authorship patterns, country affiliations, and journal preferences. Statistical tools such as trend analysis and time series analysis are applied to assess relative growth, doubling time, and predict future research trends. The data were processed and visualized using Hist Cite software, which supports quantitative scientific analysis. The choice of WoS over other databases was due to its comprehensive coverage and citation indexing capabilities.

Data Collection

The basic publication data used in this study would be derived from the Expanded Version of Science Citation Index (SCIE), Social Science Citation Index (SSCI) and Arts & Humanities Citation Index (A&HCI), which is available in Web of Science (WoS) database. The raw publication data along with their citations has been downloaded from the Web of Science Publication data for years from 2005 to 2024 were used for analyzing the growth and impact of research publications of State Universities in Tamilnadu.

Limitation of the study

There are 22 state universities in Tamil Nadu. The scope of this study is limited to 10 arts and science universities selected for the study. The remaining universities in Tamil Nadu, including those specializing in medicine, engineering, law, physical education, and open and distance education, were not included in the study.

Application of Statistical Tools and Empirical Law

Relative Growth Rate

In order to identify the relative growth rate, the researcher has adopted a model developed by Mahapatra. The relative growth rate is the increase in the number of publications per unit of time. The mean relative growth rate *R*–(1–2) over a specified period of interval can be calculated from the following equation:

$$R\ (1–2) = W2–W1/T2–T1$$

where,

R (1–2) = Mean relative growth rate over the specified period interval.

W1 = log *w1* (Natural log of initial number of publications).

*W*2= log *w*2 (Natural log of initial number of publications).

*T*2–*T*1 = the unit difference between the initial time and final time.

R (a) = Relative growth rate per unit publication per unit of time (year).

Doubling Time

Doubling time for publications can be calculated by the following formula:

Doubling time for publications Dt (a) = 0.693 /*R* (a)

Exponential Growth Rate

Exponential growth rate is used to calculate the rate of population growth. One has to understand how it is used. There are two types of growth rate such as, exponential growth rate and linear growth rate. Exponential growth rate reveals the relative growth rate of the population as it depends upon the current population. Linear growth rate, on the other hand, does not depend upon the current growth rate. So, they preferred once to calculate the exponential growth rate. Exponential growth rate can be used to predict future population of any species of animals. It is used globally to predict human population. If one knows the periodic rate i.e., the number of years through which the growth rate is to be calculated and the original population, you can calculate exponential growth rate with ease.

The formula for calculating exponential growth is given as:

$$N(t) = N(0)e\ rt$$

Where,
N (t) is the population when the time elapsed is "t" years
N (0) is the initial population
"r" is the growth rate
"t" is the number of years
"e" is the natural base of logarithms whose value is 2.711828

Annual Growth Rate

The AGR was determined as per the formula given below.

$$AGR = \frac{End\ Value - First\ Value}{First\ Value} \times 100$$

Time Series Analysis

The multivariate analysis technique namely multiple regression has been used by the researcher. The purpose of using this technique is to predict the number of publication of the near future.
The regression equation is: y = a+bx
Where y is the dependent variable (number of publications)
X is an independent variable (the reference year),
a and b are constants.

Analysis of Data

Growth of Publications output in State Universities in Tamil Nadu

Table-1 presents the publication output of ten State Universities in Tamil Nadu, along with their Total Local Citation Score (TLCS), Total Global Citation Score (TGCS), percentage contribution, and rank during the study period. The data show considerable variation in research publication output among the universities. The University of Madras recorded the highest publication output with 7,602 publications, accounting for 17.68% of the total publications, and secured first rank. It was followed by Annamalai University, which produced 7,375 publications (17.15%) and secured second rank. Bharathiar University ranked third with 7,239 publications (16.84%), while Bharathidasan University occupied the fourth position with 6,537 publications (15.20%) followed by Alagappa University contributed 4,419 publications (10.28%) and secured fifth rank, Madurai Kamaraj University produced 3,528 publications (8.20%), occupying sixth rank, Periyar University contributed 2,907 publications (6.76%) and ranked seventh, Manonmaniam Sundaranar University recorded 1,969 publications (4.58%), securing eighth rank, Thiruvalluvar University had 1,070 publications (2.49%) and ranked ninth, whereas Mother Teresa University recorded the lowest output of 353 publications (0.82%), securing tenth rank. In terms of citation impact, Bharathiar University recorded the highest TLCS of 9,966 and TGCS of 18,318, indicating a strong citation impact at both local and global levels. Annamalai University had a TLCS of 1,242 and TGCS of 15,273, while the University of Madras recorded a TLCS of 139 and TGCS of 6,302. Although the University of Madras had the highest number of publications, Bharathiar University demonstrated particularly strong citation performance.

Year-wise Distribution of Publications

Table-2 presents the year-wise distribution of research publications produced by State Universities in Tamil Nadu during the period 2005–2024. During the twenty-year period, these universities produced a total of 42,999 publications. In 2005, the State Universities collectively produced 944 publications. The output increased to 1,097 publications in 2006 and further to 1,317 publications in 2007. A marginal decline was observed in 2008, when the total output decreased to 1,286 publications. Subsequently, publication output increased to 1,352 in 2009 and 1,425 in 2010.A significant increase was observed from 2011 onwards. The total publication output reached 1,775 in 2011 and 1,780 in 2012, followed by 1,858 in 2013. In 2014, the universities produced 2,141 publications, crossing the 2,000-publication level for the first time during the study period. Although there was a slight decline to 2,121 publications in 2015, the overall trend remained upward. The publication output continued to increase during 2016–2018, reaching 2,279 publications in 2016, 2,456 in 2017, and 2,531 in 2018. A small decline occurred in 2019, when the total

output fell to 2,452 publications. Thereafter, a substantial increase was observed, with 2,847publications in 2020, 3,206 in 2021, and 3,532 in 2022. The year 2022 recorded the highest publication output during the study period.In 2023, the total publication output declined to 3,242, but it recovered in 2024, reaching 3,358 publications. Thus, despite fluctuations in some years, the overall publication trend shows a substantial increase from the beginning to the end of the study period.

Source-wise Analysis of Research Output

Table-3 presents the source-wise analysis of research output of State Universities in Tamil Nadu according to different document types. The data reveal that articles constitute most of the research output, with 39,597publications, accounting for approximately 92.09 per cent of the total output. Among the universities, University of Madras contributed the highest number of articles (7,045), followed by Annamalai University (6,769), Bharathiar University (6,611), and Bharathidasan University(6,061). Mother Teresa University recorded the lowest number of articles, with 329 publications. This indicates that journal articles are the principal form of scholarly communication among the State Universities of Tamil Nadu. The second-largest document category is Review, with 1,386 publications, representing approximately 3.22 per cent of the total output. Bharathiar University recorded the highest number of review publications (292), followed by Annamalai University(221) and Bharathidasan University(210). University of Madras contributed 180 review publications, while Mother Teresa University recorded only 6. The relatively smaller proportion of review literature indicates that the universities' research output is predominantly focused on original research articles.

Article–Proceedings Papers accounted for 420 publications, or approximately 0.98 per cent of the total output. University of Madras recorded the highest contribution (80), followed by Annamalai University (73) and Bharathidasan University (67). Similarly, Meeting Abstracts contributed 397 publications, with Bharathiar University recording the highest number (105), followed by University of Madras (102) and Annamalai University (76). The category Article–Early Access accounted for 274 publications, representing approximately 0.64 per cent of the total output. Bharathidasan University contributed the largest number in this category (47), followed by Bharathiar University (40) and Annamalai University (39). Corrections accounted for 235 publications, with Annamalai University contributing 45, Bharathidasan University44, and Bharathiar University40. These categories indicate the presence of different stages and forms of scholarly publication within the research output of the universities. The table also shows 176 retracted publications, accounting for approximately 0.41 per cent of the total output. Annamalai University recorded the highest number of retracted publications (48), followed by Bharathiar University (26) and Periyar University (22). In addition, 52 publications were classified specifically as Retractions. These figures indicate that a small proportion of the indexed research output has subsequently undergone correction or retraction.
Other conventional document types such as Letters (177), Editorial Materials (163), and Book Reviews (13) contributed relatively small proportions of the total research output. Review–Book Chapter publications accounted for 5, while Review–Early Access contributed 16 publications. Several other document categories, including Correction–Early Access, Article–Book Chapter, Reprint, Expression of Concern, and Software Review, occurred only in very small numbers

Relative Growth Rate (RGR) and Doubling Time (DT)

Table-4 presents the Relative Growth Rate (RGR) and Doubling Time (DT) of publication output of State Universities in Tamil Nadu during the period 2005–2024. In 2005, the State Universities produced 944 publications, which constituted the initial cumulative output. In 2006, the cumulative publication output increased to 2,041, and the RGR was 0.77, with a doubling time of 0.90 years. In 2007, the cumulative output increased further to 3,358 publications, while the RGR decreased to 0.50 and the doubling time increased to 1.39 years. This indicates that although publication output continued to grow, the rate of relative growth began to decline. During 2008–2010, the cumulative publication output increased from 4,644 to 7,421 publications. The RGR gradually declined from 0.32 in 2008 to 0.21 in 2010, while the corresponding doubling time increased from 2.17 to 3.30 years. This pattern indicates a gradual reduction in the relative rate of growth as the cumulative publication base became larger. In 2011, the cumulative publication output reached 9,196 publications, with an RGR of 0.22 and a doubling time of 3.15 years. The RGR

subsequently declined to 0.17 in 2012 and 0.16 in 2013, while the doubling time increased to 4.08 and 4.33 years, respectively. In 2014 and 2015, the cumulative publication output increased to 14,975 and 17,096, while the RGR decreased further from 0.15 to 0.14. The corresponding doubling time increased from 4.62 to 4.95 years. The declining relative growth trend continued during 2016–2019. The RGR decreased from 0.12 in 2016 and 2017 to 0.11 in 2018 and 0.10 in 2019. At the same time, the doubling time increased from approximately 5.78 years in 2016 to 6.93 years in 2019. This indicates that the cumulative publication output was continuing to expand, but the rate at which it was growing relative to the existing publication base was progressively slowing. During 2020–2022, the cumulative publication output increased substantially from 29,661 in 2020 to 36,399 in 2022. However, the RGR remained at approximately 0.10, while the doubling time remained around 6.93 years. This suggests that publication productivity continued to increase at a relatively stable rate during these years. In 2023, the cumulative publication output reached 39,641 publications, while the RGR declined to 0.09 and the doubling time increased to 7.70 years. By 2024, the cumulative output reached 42,999 publications, the RGR declined further to 0.08, and the doubling time increased to 8.66 years. Thus, 2024 recorded the lowest RGR and the longest doubling time in the study period.

Annual Growth Rate (AGR)of State Universities Publications in Tamil Nadu

Table-5 presents the annual growth rate (AGR) of publications produced by State Universities in Tamil Nadu during the period 2005–2024. The table provides the annual publication output, percentage contribution to the total publications, cumulative publication output, and annual growth rate. During the study period, the State Universities of Tamil Nadu produced a total of 42,999 publications, accounting for 100 per cent of the publications considered in the study. In 2005, the universities produced 944 publications, representing 2.20 per cent of the total output. The publication output increased to 1,097 publications in 2006, with an annual growth rate of 16.21 per cent. A further increase was observed in 2007, when the output reached 1,317publications, recording the highest growth rate of 20.05 per cent during the initial years. However, in 2008, the publication output declined slightly to 1,286, resulting in a negative annual growth rate of -2.35 per cent.From2009 to 2010, publication output increased gradually from 1,352 to 1,425, with annual growth rates of 5.13 per cent and 5.39 per cent, respectively. A significant increase occurred in 2011, when publications rose to 1,775, registering an annual growth rate of 24.56 per cent, which is the highest AGR recorded during the entire study period**.** In 2012, the output remained almost stable at 1,780 publications, resulting in a very low growth rate of 0.28 percent.

During 2013 and 2014, the publication output continued to increase, reaching 1,858 and 2,141publications, respectively. The corresponding annual growth rates were 4.38 per cent and15.23per cent. A marginal decline occurred in 2015, when the number of publications decreased to 2,121, resulting in a negative growth rate of -0.93 per cent. The publication output subsequently increased during 2016–2018. It rose from 2,279publications in 2016to 2,456 in 2017 and 2,531 in 2018, with annual growth rates of 7.45 percent, 7.76 per cent, and 3.05 per cent, respectively. In 2019, the output declined slightly to 2,452 publications, producing a negative growth rate of **-**3.12 per cent**.** A substantial increase in research productivity was observed from 2020 onwards. The publication output increased to 2,847 in 2020, recording a growth rate of 16.11 per cent. It further increased to 3,206 publications in 2021 and 3,532 publications in 2022, with growth rates of 12.61 per cent and 10.17 per cent, respectively. The year 2022 recorded the highest publication output**,** accounting for 8.21 per cent of the total publications.In2023, the number of publications decreased to 3,242**,** resulting in the lowest annual growth rate of -8.21 per cent during the study period. However, the publication output recovered in 2024**,** increasing to 3,358 publications and recording a positive growth rate of 3.58 per cent**.** The cumulative publication output reached 42,999 by the end of 2024.

Time Series Analysisof State Universities Publications in Tamil Nadu

Table-6 presents the time series analysis of publication output of State Universities in Tamil Nadu during the period 2005–2024. The analysis uses the year as the independent variable (**X**) and the total number of publications as the dependent variable (**Y**). The values of **X** are assigned from -9 to +10**,** with2014 taken as the base year (X = 0)**.** The total publication output for the study period is 42,999 publications, while the sum of X^2 is 670 and the sum of XY is 109,559. The publication output shows an overall increasing trend over the twenty-year study period. In 2005, the State Universities produced 944 publications, which increased to 1,097 in 2006 and 1,317 in 2007. Although there was

a slight decline in 2008 to 1,286 publications, the general trend remained upward. By 2010, the publication output had increased to 1,425, and it further increased to 1,775 in 2011and 1,780 in 2012. The output continued to rise during the subsequent years. In 2013, the universities produced 1,858 publications, increasing to 2,141 publications in 2014, the base year of the time-series analysis. Although there was a marginal decline to 2,121 publications in 2015, the publication output subsequently increased steadily, reaching 2,279 in 2016**,** 2,456 in 2017**,** and 2,531 in 2018**.** A temporary decline was observed in 2019, when the number of publications decreased to 2,452**.** However, the publication output increased substantially thereafter, reaching 2,847 publications in 2020**,** 3,206 in 2021**,** and3,532 in 2022**.** The year2022 recorded the highest publication output during the study period. Although publications declined to 3,242 in 2023**,** the output recovered to 3,358 publications in 2024. The XY values further demonstrate the direction and strength of the time-related trend. The negative XY values during the earlier years gradually changed to positive values after the base year. The positive values increased considerably in the later years, reaching 33,580 in 2024, indicating that the increase in publication output was particularly pronounced during the latter part of the study period. On the application of the formula of Time Series analysis and it is subsequently found from the results obtained separately for the years 2030, 2035, and 2040 that the future trend of growth in research literature output may follow an increasing trend. Straight line equations are applied to arrive at estimates for future growth under the Time Series analysis during the forthcoming years. The inference drawn is that there is a growth level in research literature output in state University Publication of Tamilnadu

Straight Line equation

$Yc = a + bX$

X is the median of the year

X2 is the multiplication of X

Where $XY = X2 - X$

Since $\sum x = 0$

$a = \sum Y/N = 42999/20 = 2149.95$; $b = \sum XY/\sum X2 = 109559/ 670 = 163.52$

Estimated literature in 2030 is when $x = 2030 - 2014 = 16$

$= 2149.95 + (163.52*16)$

$= 2149.95 + 2616.32$

$= 4766.27$

Estimated literature in 2035 is when $x = 2035 - 2014 = 21$

$= 2149.95 + (163.52*21)$

$= 2149.95 + 3433.92$

$= 5583.87$

Estimated literature in 2040 is when $x = 2040 - 2014 = 26$

$= 2149.95 + (163.52*26)$

$= 2149.95 + 4251.52 = 6401.47$

Overall, it confirms that Tamil Nadu state Universities research publications have shown a strong positive growth trend over the years. The continuous increase in publication output indicates expanding research activities, increasing scholarly collaboration, and greater global recognition of Tamilnadu state Universities research publications.

Exponential Growth Rate of Publication Output

Table-7 presents the exponential growth rate of publication output of State Universities in Tamil Nadu during the period 2005–2024. The table indicates that the overall research publication output increased considerably during the study period, although the annual growth pattern was not uniform.In2005**,** the State Universities of Tamil Nadu produced 944 publications, which increased to 1,097 publications in 2006 and further to 1,317 publications in 2007. The exponential growth rates during these years were 0.15 and 0.18, respectively, indicating a growth trend. However, in 2008, the publication output declined slightly to 1,286 publications, resulting in a negative exponential growth rate of -0.02**.** During 2009 and 2010, the publication output increased gradually from 1,352 to 1,425publications, with an exponential growth rate of 0.05 in both years. A notable increase occurred in 2011**,** when

the output reached 1,775 publications, recording an exponential growth rate of 0.22, the highest annual growth rate reported in the table. In 2012, the output remained almost unchanged at 1,780 publications, resulting in a growth rate of 0.00. From 2013 to 2014, publication output showed a positive trend, increasing from 1,858 to 2,141 publications, with exponential growth rates of 0.04 and 0.14, respectively. However, the output declined marginally in 2015to 2,121 publications, resulting in a negative growth rate of -0.01. The publication output subsequently increased from 2,279 publications in 2016 to2,456 in 2017and2,531 in 2018, although the corresponding growth rates remained relatively modest.

In 2019, the number of publications declined slightly to 2,452, producing a negative exponential growth rate of -0.03. A substantial recovery was observed in 2020, when the publication output increased to 2,847, with an exponential growth rate of 0.15. The upward trend continued in 2021 and 2022, when publication output reached 3,206 and 3,532 publications, respectively, with growth rates of 0.12 and 0.10. A decline was observed in 2023, when the publication output decreased from 3,532 to 3,242publications, resulting in a negative exponential growth rate of -0.09, which represents the lowest growth rate recorded during the study period. However, publication output recovered in 2024, reaching 3,358 publications, with a positive growth rate of 0.04. The highest exponential growth rate was recorded in 2011 (0.22), followed by 2007 (0.18), while the lowest growth rate occurred in 2023 (-0.09). The overall pattern suggests that research productivity among the State Universities in Tamil Nadu has expanded substantially over the study period, despite intermittent periods of stagnation or decline. The increased publication output in the later years, particularly from 2020 onwards, indicates a strengthening of research activities and scholarly productivity among the State Universities of Tamil Nadu

Year-wise Author Productivity of Publication Output

The Table 8 presents the year-wise author productivity of publication output in the State Universities of Tamil Nadu during the period from 2005 to 2024. The data show that a total of 2,00,434 authors contributed to 42,999 research articles, with an overall average of 4.54 authors per paper. In 2005, there were 2,687 authors contributing 944 articles, resulting in an average of 2.85 authors per paper and an author productivity of 0.35 articles per author. The number of authors and articles generally increased over the study period, although some fluctuations were observed. The number of authors increased steadily from 2,687 in 2005 to 11,602 in 2017, before reaching a peak of 17,909 authors in 2018. However, the number subsequently declined to 11,702 in 2019 and then increased again to 16,736 in 2021. In 2022, the number of authors decreased to 12,177, followed by a gradual increase to 12,641 in 2024. The highest number of articles was recorded in 2022, with 3,532 articles, followed by 3,358 articles in 2024 and 3,242 articles in 2023. The lowest publication output was observed in 2005, with 944 articles. The average number of authors per paper varied considerably across the years. It increased from 2.85 authors per paper in 2005 to 3.62 in 2007 and reached 5.11 in 2008. The highest average author collaboration was recorded in 2018, with 7.08 authors per paper, indicating a substantial increase in collaborative research during that year. In contrast, the lowest average was recorded in 2005, with 2.85 authors per paper. After 2021, the average declined considerably, reaching 3.45 in 2022, 3.77 in 2023, and 3.76 in 2024. Author productivity, measured as the number of articles per author, was highest in 2005 (0.35) and declined gradually during the subsequent years. The lowest productivity was observed in 2018, at 0.14 articles per author, corresponding to the unusually high number of authors per paper. Productivity improved in the later years, reaching 0.29 in 2022 and 0.27 in both 2023 and 2024.

Country-wise Collaboration of Research Publications

Table-9 presents the top 50 countries involved in research collaboration with State Universities of Tamil Nadu. The table indicates substantial international collaboration, although the extent of collaboration varies considerably across countries and universities. India occupies the first position with a total of 42,999 publications, representing by far the largest share of country-wise collaboration. The highest contribution from India is reported by University of Madras (7,602), followed by Annamalai University (7,375), Bharathiar University (7,239), Bharathidasan University (6,537), Alagappa University (4,419), Madurai Kamaraj University (3,528), Manonmaniam Sundaranar University (1,969), Periyar University (2,907), Thiruvalluvar University (1,070)and Mother Teresa women University(353). This dominance indicates that the research output of the State Universities of Tamil Nadu is strongly connected with the

national research network. Among foreign countries, Saudi Arabia ranks first with 3,410 publications, followed closely by South Korea with 3,370 publications. Saudi Arabia shows relatively consistent collaboration across the universities, with the highest contribution from Bharathidasan University (597), while South Korea records its highest collaboration with Bharathiyar University (899). People's Republic of China ranks fourth with 1,944 publications, with Bharathiar University contributing the largest number (499), followed by Bharathidasan University (296) and Alagappa Univesity (279).

Taiwanranks fifth with 1,300 publications, with particularly strong collaboration with BU (459) and Alagappa University (199). The United States of America ranks sixth with 2,175publications, showing notable collaboration with Bharathiar University (449), Bharathidasan University (326), University of Madras (372), Annamalai University (269), and Madurai Kamaraj University (259). This indicates that the United States is an important international research partner for several universities. Among European countries, Italy (836), the United Kingdom (598), Germany (409), France (368), Spain (340), and Poland (282) show considerable levels of collaboration. Italy has relatively broad participation across the universities, whereas Germany and France show stronger collaboration with selected institutions. The United Kingdom demonstrates collaboration across almost all the universities, with Bharathidasan University (109), Bharathiar University (96), Madurai Kamaraj University (72), and University of Madras (71) making notable contributions. Asian countries also constitute an important component of the collaboration network. Malaysia records 946 publications, making it one of the most significant international partners. Collaboration with Malaysia is particularly high for University of Madras (201), Annamalai University (135), Bharathiar University (129), Madurai Kamaraj University (121), and BDU (105). Japan (788) also occupies a prominent position, with BU (149), UNOM (191), Bharathidasan University (109), and Alagappa University (88) contributing substantially. Singapore (304), Thailand (365), Vietnam (362), Iran (254), and the United Arab Emirates (308) also demonstrate meaningful research collaboration. The data further reveal collaboration with countries from Africa, Latin America, the Middle East, and Eastern Europe. South Africa contributes 346 publications, Ethiopia 274, Egypt 309, Chile 331, Brazil 269, Turkey 205, and Russia 282. Although these countries have comparatively lower levels of collaboration than the leading partners, their presence indicates that the State Universities of Tamil Nadu have established research connections extending across different geographical regions.

Major Findings

- The findings reveal that the University of Madras, Annamalai University, Bharathiar University, and Bharathidasan University emerged as the leading contributors to research productivity among Tamil Nadu State Universities.
- The year-wise analysis indicates that research productivity showed a significant long-term increase, rising from 944 publications in 2005 to 3,358 publications in 2024, despite fluctuations in some years.
- The findings clearly demonstrate that journal articles were the dominant form of scholarly communication, followed by review articles and conference proceedings.
- The findings reveal an inverse relationship between Relative Growth Rate (RGR) and Doubling Time, with a mean RGR of 0.19 and a mean doubling time of 4.67 years.
- The study found a substantial increase in the number of authors per publication, indicating a growing trend towards collaborative and multi-authored research.
- The time-series analysis indicates a substantial upward trend in research publication output from 2005 to 2024, increasing from 944 to 3,358 publications. A total of 42,999 publications were produced during the study period, confirming the overall growth in research productivity over time.
- Tamil Nadu State Universities have established a broad international research collaboration network, with major research partnerships involving Saudi Arabia, South Korea, the United States, China, Taiwan, Malaysia, Japan, Italy, the United Kingdom, and Australia.
- The universities differed in their research performance, with some demonstrating higher publication productivity, while others showed greater citation impact.

ABSTRACT

Abstract

In this paper, we examine the non-linear Exponential Diophantine equations with coefficients as Fortunate numbers and Ramanujan Prime numbers $17^x + 19^y = z^2$,$29^x + 167^y = z^2$ and $11^x + 53^y = z^2$ respectively, where x, y, and z are non-negative integers. It has been shown that there is only a unique non negative solution to these non-linear Diophantine Equations.

Keywords: Exponential Diophantine Equation, Prime numbers, Catalan Conjecture, Integer solutions.

INTRODUCTION

Number theory is an area of mathematics that examines the characteristics of positive integers like 1, 2, and 3. Often referred to as "higher arithmetic," it is one of the most natural and ancient branches of mathematics. Both professional and amateur mathematicians have always been attracted by number theory. Although solutions to the issues and proofs of the theorems frequently need for a sophisticated mathematical background, number theory problems and theorems can often be grasped by laypeople, in contrast to other disciplines of mathematics. Number theory, which has no direct applications to the actual world, was thought to be the most pure area of mathematics until the middle of the 20th century. The development of digital computers and communications showed that number theory may offer novel solutions to practical issues [1–3]. Fortunate numbers are a concept related to

number theory and have connections to other number sequences and properties. While there may not be a vast amount of literature specifically dedicated to fortunate numbers alone, you can explore broader topics in number theory and related concepts that may include fortunate numbers as a part of their discussions. While fortunate numbers might not have an entire book dedicated to them, books on special numbers or sequences often cover a variety of interesting number patterns. For example."The Penguin Dictionary of Curious and Interesting Numbers" by David Wells explores various mathematical curiosities [4].

An exponential Diophantine equation is a type of Diophantine equation where the variables appear as exponents. In other words it is an equation of the form $a^x + b^y = z^2$ where a,b,x,y are integers. Diophantine equations come in a variety of forms which have historically piqued the interest of researchers. In 2013, Sroysang [5] proved that the Diophantine equation $7^x + 8^y = z^2$where x, y and z are non negative integers, has the unique solution $(x,y,z) = (0,1,3)$. In 2014, Sroysang [5] proved that the Diophantine equations $7^x + 19^y = z^2$ and $7^x + 91^y = z^2$ have no solution, where x, y and z are non-negative integers. In 2017, Acu [6] showed that the Diophantine equation $2^x + 5^y = z^2$ where x,y and z are non negative integers, has only two solutions $(x, y,z) = (3,0,3)$ and $(2,1,3)$. In 2018, Burstein wrote a note on the Diophantine equation $2^a + 7^b = z^2$ where a and$b$ are odd integers. In this paper, we have showed that (1,1,6) is a unique non-negative solution of Fortunate Number Exponential Diophantine equation $17^x + 19^y = z^2$and (1,1,14) is a unique non-negative solution of Ramanujan Prime number Exponential Diophantine equation $29^x + 167^y = z^2$ and (1,1,8) is a unique non-negative solution of Sophie German Prime number Exponential Diophantine equation$11^x + 53^y = z^2$.

Preliminaries

Definition 2.1: A Fortunate number, named after Reo Fortune, is the smallest integer m > 1such that, for a given positive integern, $p_n + m$ is a prime number, where the primorial p_n is the product of the first n prime numbers.

Example: For example, if n is 3 , then p_n is 2.3.5 = 30,$p_n + m$ is 37 , and m is the prime 7 , that is third Fortunate number. The Fortunate numbers for the first primorials are: 3,5,7,13, …

Definition 2.2: Ramanujan derived a generalized result, and that is: $\pi(x) - \pi\left(\frac{x}{2}\right) \geq$ 1,2,3,... for all $x \geq$ 2,11,17,... respectively where $\pi(x)$ is the prime-counting function, equal to the number of primes less than or equal to x.

The converse of this result is the definition of Ramanujan primes:

The nth Ramanujan prime is the least integer R_n for which $\pi(x) - \pi\left(\frac{x}{2}\right) \geq n$ for all $x \geq R_n$. In other words: Ramanujan primes are the least integers R_n for which there are at least n primes between x and $x/2$ for all $x \geq R_n$.

The Ramanujan primes are thus 2,11,17,29, ...

Note that the integer R_n is necessarily a prime number: $\pi(x) - \pi\left(\frac{x}{2}\right)$ and, hence, $\pi(x)$ must increase by obtaining another prime at $x = R_n$. Since$\pi(x) - \pi\left(\frac{x}{2}\right)$can increase by at most 1, $\pi(R_n) - \pi\left(\frac{R_n}{2}\right) = n$.

Definition 2.3: (Sophie German Prime) A prime number that remains prime after being multiplied by 2 and adding 1 to the result (ie) $2p + 1$.

Example: 11 is a Sophie German Prime because 2*11+1=23, both 11 and 23 are prime numbers.

Proposition

Proposition 3.1 (Catalan Conjecture) The solution of the Diophantine equation $a^x - b^y = 1$ where a, b, x, y are integers with $\min\{a, b, x, y\} > 1$ has a unique solution and is given by $(a, b, x, y) = (3,2,2,3)$

Lemma 3.1 The Diophantine equation $1 + 19^y = z^2$, wherey, z are integers has no non-negative integer solution.

Proof: Take the equation $1 + 19^y = z^2$ into consideration. According to proposition 3.1, y has a value between 0 and 1. The aforementioned equation becomes $z^2 = 2$, which is not feasible, if y = 0. The preceding equation becomes $z^2 = 20$ if y = 1, demonstrating that z is not an integer solution. Consequently, $1 + 19^y = z^2$has no integer answer.

Lemma 3.2 The Diophantine equation $1 + 167^y = z^2$, wherey, z are integers has no non-negative integer solution.
Proof: Take the equation$1 + 167^y = z^2$. y is given the values 0 and 1 by proposition 3.1. The aforementioned equation becomes $z^2 = 2$ and is illogical if y = 0, which is the case. It is clear that z is not an integer solution.If y = 1 because the aforementioned equation changes to z^2= 168. As a result, $1 + 167^y = z^2$ has no integer solution.

Lemma 3.3 The Diophantine equation $1 + 53^y = z^2$, wherex, z are integers has no non-negative integer solution.
Proof: yhas a value between 0 and 1. Therefore the equation becomes $z^2 = 2$ if $y = 0$ not feasible. If $y = 1$, the equation becomes $z^2 = 54$ has no integer solution. Hence, $1 + 53^y = z^2$has no integer solution.

Lemma 3.4 The Diophantine equation $17^x + 1 = z^2$, wherex, z are integers has no non-negative integer solution.
Proof: Consider the expression $17^x + 1 = z^2$. According to proposition 3.1, x has the values 0 and 1.Ifx = 0, the preceding equation becomes $z^2 = 2$, which is not a valid solution. If x = 1, the preceding equation becomes $z^2 = 18$, demonstrating that z is not an integer answer. As a result, there is no integer solution for $17^x + 1 = z^2$.

Lemma 3.5 The Diophantine equation $29^x + 1 = z^2$, wherex, z are integers has no non-negative integer solution.
Proof: Consider the expression $29^x + 1 = z^2$. According to proposition 3.1, x has the values 0 and 1.Ifx = 0, the following equation transforms into$z^2 = 2$, which is not conceivable. If x = 1, the above equation becomes $z^2 = 30$, indicating that z is not an integer. As a result, there is no integer solution for $29^x + 1 = z^2$.

Lemma 3.6 The Diophantine equation $11^x + 1 = z^2$, wherex, z are integers has no non-negative integer solution.
Proof: xhas a value between 0 and 1. Therefore the equation becomes $z^2 = 2$ if x = 0is not exists. If $x = 1$, the equation becomes $z^2 = 12$ has no integer solution. Hence, $11^x + 1 = z^2$has no integer solution.

Main Theorems

Theorem 4.1 The unique solution (x, y, z) to the Diophantine equation $17^x + 19^y = z^2$in non-negative solution is (1,1,6).

Proof: Let x, y, zbe non-negative integer and consider the case when one of the three unknowns x, y, z to be zero. If z = 0, is obviously not possible. If x or y is zero then by Lemma 3.1 and 3.4we can show that there exist no non-negative solution for the equation $17^x + 19^y = z^2$. Hence we continue the case when $\min\{x, y, z\} > 0$. Consider the equation$17^x + 19^y = z^2$. Here z^2 is an even number, so z is even. Thus let z = 2k for some non-negative integer k. Then $z^2 \equiv 0(\text{mod}4)$and $17^x \equiv 1(\text{mod})$. It follows that $19^y \equiv 3(\text{mod}4)$, when y is an odd number. So let $y = 2m + 1$ for some non-negative integer m. We divide x into two cases.

Case 1: When x is even. Let $x = 2t$ for some non-negative integer t. Then $17^{2t} + 19^y = z^2$ and hence $19^y = z^2 - 17^{2t} \Rightarrow 19^y = (z + 17^t)(z - 17^t)$. $19^u = (z - 17^t), 19^{y-u} = z + 17^t$.Therefore, $19^{y-u} - 19^u = 2(17^t)$. This gives us the value u = 0and $2(17^t) = 19^y - 1$. That is impossible since $2(17^t) \equiv 0(\text{mod}17)$but $19^y - 1 \neq 0(\text{mod}17)$. Thus $17^x + 19^y = z^2$ has no non-negative integer solution when x is even.

Case 2: When x is odd. Let $x = 2t + 1$. Then $17^{2t+1} + 19^{2m+1} = (2k)^2$. Hence $17(17^{2t}) + 19(19^{2m}) = 4k^2 \Rightarrow 17(17^{2t}) + 51(19^{2m}) - 32(19^{2m}) = 4k^2 \Rightarrow 17\{17^{2t} + 3(19^{2m})\} = 4\{k^2 + 8(19^{2m})\}$. Hence $17^{2t} + 3(19^{2m}) = 4$ and $k^2 + 8(19^{2m}) = 17$. This gives the value $m = 0, t = 0, k = 3$. Therefore, the Diophantine equation $17^x + 19^y = z^2$ has a non-negative integer solution $(x, y, z) = (1, 1, 6)$.

Theorem 4.2 The unique solution (x, y, z) to the Diophantine equation $29^x + 167^y = z^2$in non-negative solution is (1,1,14).

Proof. Let x, y, zbe non-negative integer and consider the case when one of the three unknowns x, y, z to be zero. If z = 0, is obviously not possible. If x or y is zero then by Lemma 3.2 and 3.5we can show that there exist no non-negative solution for the equation $29^x + 167^y = z^2$. Hence we continue the case when $\min\{x, y, z\} > 0$.

Consider the equation$29^x + 167^y = z^2$. Here z^2 is an even number, so z is even. Thus let $z = 2k$ for some non-negative integer k. Then $z^2 \equiv 0(\text{mod}4)$and $29^x \equiv 1(\text{mod}4)$. It follows that $167^y \equiv 3(\text{mod}4)$, when y is an odd number. So let $y = 2m + 1$ for some non-negative integer m. We divide x into two cases.

Case 1: When x is even. Let $x = 2t$ for some non-negative integer t. Then $29^{2t} + 167^y = z^2$ and hence $167^y = z^2 - 29^{2t} \Rightarrow 167^y = (z + 29^t)(z - 29^t)$. $167^u = (z - 29^t), 167^{y-u} = z + 29^t$. Therefore, $167^{y-u} - 167^u = 2(29^t)$. This gives us the value $u = 0$and $2(29^t) = 167^y - 1$. That is impossible since $2(29^t) \equiv 0(\text{mod}29)$but $167^y - 1 \neq 0(\text{mod}29)$. Thus $29^x + 167^y = z^2$ has no non-negative integer solution when x is even.

Case 2: When x is odd. Let $x = 2t + 1$. Then $29^{2t+1} + 167^{2m+1} = (2k)^2$. Hence $29(29^{2t}) + 167(167^{2m}) = 4k^2 \Rightarrow 29(29^{2t}) + 87(167^{2m}) + 80(167^{2m}) = 4k^2 \Rightarrow 29\{29^{2t} + 3(167^{2m})\} = 4\{k^2 - 20(167^{2m})\}$. Hence $29^{2t} + 3(167^{2m}) =$ 4and $k^2 - 20(167^{2m}) = 29$. This gives the value $m = 0, t = 0, k = 7$. Therefore, the Diophantine equation $29^x + 167^y = z^2$ has a non-negative integer solution (x, y, z) = (1, 1,14).

Theorem 4.3 The unique solution (x, y, z) to the Diophantine equation $11^x + 53^y = z^2$in non-negative solution is (1,1,8).

Proof: Let x, y, zbe non-negative integer and consider the case when one of the three unknowns x, y, z to be zero. If $z = 0$, is obviously not possible. If x or y is zero then by Lemma 3.3 and 3.6we can show that there exist no non-negative solution for the equation $11^x + 53^y = z^2$. Hence we continue the case when $\min\{x, y, z\} > 0$.

Consider the equation$11^x + 53^y = z^2$. Here z^2 is an even number, so z is even. Thus let $z = 2k$ for some non-negative integer k. Then $z^2 \equiv 0(\text{mod}4)$and $11^x \equiv 3(\text{mod}4)$. It follows that $53^y \equiv 1(\text{mod}4)$, when y is an odd number. So let $y = 2m + 1$ for some non-negative integer m. We divide x into two cases.

Case 1: When x is even. Let $x = 2t$ for some non-negative integer t. Then $11^{2t} + 53^y = z^2$ and hence $53^y = z^2 - 11^{2t} \Rightarrow 53^y = (z + 11^t)(z - 11^t)$. $53^u = (z - 11^t), 53^{y-u} = z + 11^t$. Therefore, $53^{y-u} - 53^u = 2(11^t)$. This gives us the value $u = 0$and $2(11^t) = 53^y - 1$. That is impossible since $2(11^t) \equiv 0(\text{mod}11)$but $53^y - 1 \neq 0(\text{mod}11)$. Thus $11^x + 53^y = z^2$ has no non-negative integer solution when x is even.

Case 2: When x is odd. Let $x = 2t + 1$. Then $11^{2t+1} + 53^{2m+1} = (2k)^2$. Hence $11(11^{2t}) + 53(53^{2m}) = 4k^2 \Rightarrow 11(11^{2t}) + 33(53^{2m}) + 20(53^{2m}) = 4k^2 \Rightarrow 11\{11^{2t} + 3(53^{2m})\} = 4\{k^2 - 5(53^{2m})\}$. Hence $11^{2t} + 3(53^{2m}) =$ 4and $k^2 - 5(53^{2m}) =$ 11. This gives the value $m = 0, t = 0, k = 4$. Therefore, the Diophantine equation $11^x + 53^y = z^2$ has a non-negative integer solution (x, y, z) = (1, 1,8).

CONCLUSION

Mathematics is an evolving field, and research on specific number sequences and properties continues to develop. If fortunate numbers, Ramanujan Prime and Sophie German Prime numbers are a relatively new or niche concept, you may find fewer resources dedicated solely to them, but exploring broader topics in number theory can help you uncover related information. In this paper, we have shown the solutions of the Diophantine equations $17^x + 19^y = z^2$,$29^x + 167^y = z^2$and $11^x + 53^y = z^2$. One can find the solutions of the Exponential Diophantine equations using other primes.

ABSTRACT

Liposomes are versatile nanocarriers widely investigated for their potential in drug delivery applications. Their unique bilayer structure enables the encapsulation of both hydrophilic and hydrophobic therapeutic agents, thereby enhancing drug solubility, stability, and bioavailability. Despite the development of numerous chemotherapeutic agents and gene therapies, their clinical efficacy is often limited by systemic toxicity, poor bioavailability, and inadequate accumulation at target sites. Liposomal drug delivery systems address these challenges by enabling targeted delivery, reducing adverse effects, and improving therapeutic outcomes. Additionally, liposomes can be engineered to optimise physicochemical properties, such as size, surface charge, and lipid composition, to enhance drug delivery performance. This review highlights the classification, preparation methods, physicochemical properties, advantages, limitations, and diverse applications of liposomes in pharmaceuticals, biotechnology, and

related fields. Furthermore, current advancements and future perspectives in liposomal drug delivery systems are discussed, emphasizing their growing importance in modern therapeutics.

Keywords: Liposomes, Drug Delivery, Nanocarriers, Bioavailability, Targeted Therapy

INTRODUCTION

Recent advancements in the field of drug delivery systems have substantially enhanced the understanding of drug interactions with target tissues. Although several chemotherapeutic drugs and novel gene therapies have been discovered over the last few decades, their potential is often limited by systemic toxicity and inadequate concentration at target sites. Often, this inability to reach effective concentrations is due to intrinsic factors of the tumour microenvironment, together with bioactivity and bioavailability issues related to drugs. For instance, some tumour types, like PDAC, contain dense desmoplastic stroma, preventing drug penetration and reducing treatment effectiveness [1]. Another limiting factor is rapid systemic circulation elimination of the drugs and their metabolic transformation in the body, which in turn decreases bioavailability of the drugs [3] – a property that correlates strongly with APIs' dissolution rate. As such, increasing the solubility has been one of the major methods employed to increase therapeutic efficiency, driving the creation of novel nano-scale drug delivery systems. One of the most important technologies here is liposomes, which can be readily adjusted through modifications in preparation techniques [10]. Liposomes can be fabricated across a broad size spectrum, ranging from a few nanometers to several micrometres, and their compositional flexibility allows precise control over bilayer rigidity, permeability, and stability through the selection of lipid constituents [11]. Furthermore, surface functionalization techniques allow for the customization of liposomes to suit diagnostic, therapeutic, and image-guided drug delivery purposes. These modifications confer significant benefits compared to other nanocarriers and address numerous challenges related to disease diagnosis, targeted delivery, and treatment efficacy.

Liposomes may be classified according to their structure, size, and preparation method. Based on structural organization, they are divided into unilamellar, oligolamellar, and multilamellar vesicles, distinguished by the number of lipid bilayers they contain. Unilamellar vesicles comprise a single lipid bilayer and typically exhibit diameters ranging from 50 to 250 nm; their comparatively large internal aqueous compartment makes them well-suited for the encapsulation of hydrophilic drugs. Conversely, multilamellar vesicles consist of multiple concentric lipid bilayers and are generally larger, with sizes ranging from 1 to 5μm. Their elevated lipid content facilitates efficient passive loading of lipophilic drugs. Owing to these favourable characteristics, liposomes underpin numerous scientific studies and serve as a foundational platform for the development and refinement of contemporary nanocarrier systems [9].

Advantages

- **Targeted Drug Delivery**: Liposomes possess the capability to encapsulate therapeutic compounds and facilitate their selective delivery to designated tissues or cellular targets, thereby enabling precise treatment interventions. This strategy minimizes drug distribution to non-target healthy tissues, consequently reducing the incidence of adverse side effects.
- **Sustained Drug Release:** Liposomal formulations can provide controlled and sustained drug release over time, prolonging therapeutic effects and decreasing the frequency of administration.
- **Preservation of Labile Compounds**: The liposome technology helps protect labile pharmaceuticals and biological compounds against damage by environmental conditions like enzymatic reactions, changes in pH, and oxidative stress.
- **Versatility and tunability:** Liposomes can be designed with precision as far as their dimensions, lipid makeup, and surface modification are concerned to maximize their functionality in particular medical uses.

- **Low Toxicity:** Delivery via liposomes can reduce drug toxicity due to targeted delivery into only the disease-affected body parts.
- **Better Cell Penetration:** Liposomes promote cell penetration of therapeutic compounds.
- **Cosmetic Uses:** As cosmetic ingredients, liposomes increase the effectiveness of compounds that have been incorporated into them due to higher penetration levels.
- **Food Industry Uses:** The food industry uses liposomes in the process of packaging nutrients, flavourings, and vitamins in order to enhance food stability and prolong its shelf life.
- **Vaccine Delivery:** Liposomes based vaccines demonstrate improved delivery efficiency, stability, and capacity to stimulate the human immune system.
- **Biocompatibility:** Due to their good biocompatibility, liposomes are suitable for use in various applications in the cosmetics and medicine sectors.
- **Application in Research:** Liposomes may be applied in biomedical studies for the delivery of different biomolecules and compounds into cells.
- **Diagnostics:** Liposomes are used in diagnostics to detect disease markers and monitor drugs.
- **Increased Immunogenicity:** Liposomes based vaccines may improve vaccine immunogenicity and immune response efficiency.
- **Customisation Potential:** Physical and chemical characteristics of liposomes, including size and charge, may be tailored for specific applications.\

Disadvantages

- **Complexity:** Creating liposomal preparations may require special skills and be complicated, which might make such technology inaccessible to some researchers and manufacturers.
- **Cost:** Manufacturing of liposomal preparations may be quite costly, which may cause the increased cost of produced drugs.
- **Compatibility Issues:** All kinds of drugs cannot be used in liposomes because of possible chemical or physical incompatibility.
- **Clinical Transition:** Though promising in preclinical testing, many preparations based on liposomes cannot overcome transition problems and get approval for clinical use.
- **Interaction with Biological System:** Preparation of liposomes may affect protein-drug interaction negatively or lead to other changes in drug functioning.
- **Biodegradability:** Based on the composition, liposomes may have poor biodegradability.
- **Niche Usefulness:** Not all drugs need to be delivered by using liposomes, which means that such technology is not universal enough.
- **Controlled Release:** Precise regulation of the release of liposomes may be complicated, which complicates their application in specific cases.
- **Regulatory Process:** Regulatory clearance of liposomes as a new drug carrier is rather complicated.

Physiochemical Properties

The efficacy of liposomes as drug carriers can be determined by their physicochemical properties, which determine how the entrapped compounds interact within the body. When the liposome is stable, the properties play a critical role in determining the efficiency of drug delivery; however, if the liposome disintegrates very fast or leaks the drug into the surrounding medium, then the outcome will depend on the physicochemical properties of the drug itself. As such, different physicochemical properties can have a bearing on liposomes' performance; thus, their assessment is necessary before use. To this end, certain parameters need to be considered by the FDA for liposomes to be approved for clinical use. The main physicochemical properties that need to be considered include particle size and distribution, zeta potential, shape, structure, drug encapsulation efficiency, drug release mechanism, and phase transition temperature. Particularly, the size and polydispersity index of the liposome are crucial since they determine the efficiency of drug encapsulation. Optimal sizes of particles are those ranging between 50nm and 200nm. Liposome shapes can be determined by using electron microscopy techniques, while the phase transition temperature is associated with the stability and drug release and increases with chain length.

Classification

Liposomes have high versatility and can be classified depending on parameters like size of particles, number of lipid layers, any modification and production method. Each of the liposome types is specially developed for use in different purposes. Liposomes are commonly differentiated based on size and lamellarity into three major types: multilamellar vesicles (MLV), large unilamellar vesicles (LUV) and small unilamellar vesicles (SUV) [7,8].

MLV consists of several concentric lipid layers that can accommodate both hydrophilic and hydrophobic substances. LUV possesses a single lipid layer encircling a large aqueous core, thus allowing it to deliver hydrophilic medications. The structure of an SUV is characterized by a single lipid layer; however, its size usually does not exceed 100 nm. This leads to increased cellular uptake and prolongation of time spent in the blood flow.Preparation of Multilamellar Vesicles. The preparation of multilamellar vesicles represents one of the most straightforward methodologies among liposome fabrication techniques. In this process, an organic solvent, initially employed to dissolve lipid components, concurrently serves as an intermediate medium in liposome formation. Specifically, egg lecithin, cholesterol, and phosphatidylglycerol were utilized in a molar ratio of 0.9:1.0:0.1, respectively. Initially, each lipid component is individually dissolved in the organic solvent. Subsequently, these solutions are combined in the specified proportions to ensure a homogeneous distribution of lipids within the mixture. The lipid mixture is then subjected to drying under a nitrogen gas stream to form a thin lipid film within the test tube. To eliminate residual traces of the organic solvent, the dried lipid film is further desiccated in a vacuum chamber for a minimum duration of 4 to 6 hours. Multilamellar vesicles constitute the most prevalent class of liposomes, primarily due to their structural configuration, which enables the encapsulation of all entrapped agents within a singular internal aqueous compartment.

Uses

Serving as artificial blood substitutes. Acting as models for artificial cells. Functioning as carriers for radiopharmaceuticals and diagnostic imaging agents. Delivering anticancer drugs. Acting as antifungal agents. Supporting antiviral therapies. Serving as vehicles in gene therapy. Delivering analgesics. Facilitating ophthalmic drug delivery. Enabling photodynamic therapy [24,25].

Limitation:

The first limitation is that, even though CNS disorders, such as stroke[2–3], epilepsy[4], and major depressive disorder[5], are widespread, this paper does not discuss their current treatments in detail. Secondly, this review places more emphasis on liposomes as intelligent drug carriers for CNS diseases rather than on the underlying mechanisms. Thirdly, although the importance of liposomes in the treatment of brain disorders has been highlighted, many of the cited studies are limited to laboratory stages and have not yet reached clinical trials. The applicability of liposomes in clinical settings is associated with several challenges, including drug stability, targeting efficiency, and safety. All these issues require further research and optimization. Another technological constraint is related to sterilization techniques. Sterilization using heat and filtration adversely affects the composition of liposomes and reduces drug loading and efficiency. It becomes difficult to obtain high drug loading for hydrophilic and hydrophobic molecules without compromising on other factors like stability and drug release rates. Liposomes represent an extremely promising tool for gene therapy. However, low transfection rates constitute a serious drawback. Following cellular uptake through endocytosis, liposomal vectors may not be able to release the genetic cargo because of failure to exit endosomes. As a result, the genetic material is exposed to enzymes of lysosomes capable of breaking it down and significantly diminishing the potential efficacy of the treatment. Such issues emphasize the complexity associated with the development of effective liposomal vectors for nucleic acid delivery.

The multifunctionality of liposomes in various fields of biomedicine, nutrition, agriculture, and many others makes formulation even more challenging.

Composition

The most important component of liposomes is represented by phospholipids, which can generally be divided into two major classes, namely glycerophospholipids and SMs. Eukaryotic cells mainly contain glycerophospholipids,

where glycerol constitutes the base structure. Their chemical formula is represented by a hydrophilic head group and one or several hydrophobic tails. Diversity in glycerophospholipids comes from variation in the head group (PC, PE, PS, PI, PA, PG, CL) and the length/saturation of tails (dimyristoyl, dipalmitoyl, or distearoyl PC, etc.). The connection between glycerol and fatty acids (ester or ether bonds) adds to the variety of glycerophospholipid structures. Sphingomyelins, however, consist of sphingosine backbones as opposed to glycerol. The acyl chains of SMs are joined to the backbone by an amide linkage and contain double bonds that are cis-oriented. Natural sphingomyelins typically have longer acyl chains compared to their sphingosine units, making them asymmetrical molecules. Sphingomyelins have the capacity for both intra- and inter-molecular hydrogen bonding. Sphingomyelins incorporated into liposomal formulations have been demonstrated to exhibit high drug entrapment efficiencies, improved serum stabilities, and faster release rates of drugs when compared with liposomes made using DSPC [21–23]. Amongst all the glycerophospholipids, phosphatidylcholine is the most frequently utilized compound in liposomal formulations. It may be isolated from natural sources or synthesized semi-chemically or chemically. Molecules of phosphatidylcholine are hydrophobic in nature, and hence, when dissolved in aqueous solvents, phosphatidylcholine molecules aggregate together spontaneously, resulting in the formation of planar bilayer sheets of minimum water interaction. Bilayer sheets subsequently collapse to form closed spherical capsules called liposomes [13,14].

Preparations:

Several methods have been formulated for the preparation of liposomes over the years. The following section discusses some of the methods used in the preparation of liposomes. It is important to note that there are usually three major steps of liposome modifications (Ajeeshkumar et al., 2021). The first step involves dehydration of the lipids in organic solvents to guarantee the full solubility of the phospholipids and cholesterol. The lipophilic modifiers, along with the encapsulated substances, are incorporated into the organic solvent before the dehydration process, while the hydrophilic modifiers are incorporated in the later stages. Some of the goals achieved by liposomal nanoformulations include the production of a monodisperse particle having a low size distribution, achieving lamellarity, drug encapsulation, and colloidal stability. There are several common preparation procedures, which involve mixing of lipids that have been dissolved in volatile organic solvents with the aqueous phase. Nevertheless, the application of organic solvents can change the physicochemical characteristics of the entrapped bioactive compounds and influence the stability as well as possible toxicity of the final nanoformulation [65]. The process of liposome synthesis commonly includes a number of essential stages. At first, the lipids should be dissolved in the organic solvent for a good blending. Then, the solvent needs to be evaporated, thus creating the lipid film. It is followed by the hydration of the lipid film using the aqueous phase under stirring or shaking, which results in the formation of liposomes. Later, the vesicles are resorted to, and their lamellarity is modified. Finally, the synthesis ends up with such steps as purification and sterilization of the nanoparticles.

Thin film hydration:

Thin film hydration is one of the most common methods used to create liposomes (Bangham et al., 1965). This process involves dissolving lipids and amphiphiles in an organic solvent to create a uniform solution. Then, under vacuum, the organic solvent is evaporated and forms a thin layer of lipids that are hydrated with a proper buffer, creating liposomes spontaneously. Liposomes created by this process usually have a wide distribution of sizes, although their size and lamellar structures can be controlled with other techniques such as ultrasonication, extrusion under high pressure, etc. (Zhang, 2023). Ultrasonication of probe type can negatively affect phospholipids structure, have lower efficiency of encapsulation, and cause some metallic contamination. Therefore, water bath sonication should be used as a gentler alternative.In spite of its simplicity and popularity, the process of thin film hydration has some major disadvantages. In particular, a relatively large amount of organic solvents is required, which makes this technique difficult to scale up.

Reverse phase evaporation:

Reverse-phase evaporation was first proposed by Szoka and is widely used for liposome preparation, especially for drug loading in water-soluble compounds and macromolecules such as antibiotics, insulin, and nucleic acids (Szoka

and Papahadjopoulos, 1978). Like the thin film-hydration method, reverse phase evaporation starts by dissolving phospholipids in an organic solvent, resulting in the formation of a lipid film via solvent evaporation under reduced pressure. A dried lipid film is then re-dissolved in the organic solvent, after which an aqueous phase is added. Ultrasonication is used to produce an oil-in-water emulsion, while solvent evaporation under reduced pressure results in the formation of liposomes. Reverse-phase evaporation produces liposomes with a large aqueous core and high entrapment efficiency; therefore, this method is suitable for preparing liposomes containing hydrophilic drugs on a laboratory scale [26].

Solvent Injection Method:

Solvent injection technique includes the use of solubilization of lipids within an organic solvent that is injected into an aqueous medium to spontaneously create liposomes. Of all the organic solvents used to achieve this, the most popular include ethanol and ether, used to form liposomes through the nano-formulation technique [65–68].

Detergent removal method:

One of the commonly applied methods for preparing large unilamellar vesicles is the detergent removal method, which is also referred to as adsorbent removal. It involves the use of detergent micelles to solubilize the phospholipids in an aqueous solution before removing the detergent by dialysis so that the phospholipids can be induced to aggregate themselves to form the desired large unilamellar vesicles. Despite its effectiveness, some constraints come along with this method. For instance, the presence of detergent contamination may pose problems when preparing the liposomes.

Applications:

From a medical perspective, the use of liposomes as delivery carriers for biological materials is common practice. Due to their excellent stability and favorable toxicity properties, liposomes have been extensively studied for potential uses in gene therapy [23] and drug delivery [24], frequently outperforming traditional approaches. The special double-layered membrane structure of liposomes makes them suitable for the encapsulation of hydrophilic biomaterials and drugs, facilitating cell entry and increasing solubility in biological membranes [25]. Over the past decade, there has been significant interest in liposomal systems, primarily because they offer safer options compared to viral vectors. The reason for this is their low immunogenicity, lower toxicity, and ability to carry larger cargo [26,27]. Liposomes also display a tendency to preferentially accumulate in targeted tissue areas, leading to better biodistribution [28]. There are several clinically approved formulations that utilize liposomes for intravenous, intramuscular [29], and oral drug delivery [30]. Their efficacy relies on various parameters, including the method used to load the drug onto the carrier, the chemical composition of the lipid bilayer, and the environment within the target tumour area [31]. The majority of FDA-approved liposomal drugs contain polyethylene glycol groups (PEG) to extend the circulation time and shield the entrapped substances from degradation by the tissue or cellular environment. Liposomal-based drug delivery systems have been developed and introduced to clinical applications [32], and they have already found applications in various medical fields such as cancer treatment, antifungal and anti-inflammatory medications, and gene delivery. Examples of some FDA-approved liposomal formulations are Doxil™, AmBisome® and DepoDur [32].

Drug Delivery: [45] Liposomes have been widely used in drug delivery, where they can be utilized for delivering drugs that include both hydrophilic and hydrophobic drugs. Liposomes improve drug solubility, stability, and bioavailability, and allow targeting of drugs to specific tissues or cells to reduce side effects.

Vaccines: [46–49] In developing vaccines, liposomes act as adjuvants or carrier systems that increase the immunogenicity by facilitating improved delivery of antigens into immune cells.

Cosmetics and Skin care: [50,51] Liposomes have been used in cosmetics and skincare preparations in order to deliver nutrients such as vitamins to the skin through a controlled release of the nutrient molecules.

Diagnostic Uses: For diagnostic imaging purposes, liposomes are carriers for contrast agents used in imaging techniques like magnetic resonance imaging (MRI) and ultrasound. This allows for more precise and targeted imaging of specific tissues or cells.

Cancer Treatment: Liposome preparations of anticancer drugs, including liposomal doxorubicin (Doxil®), are commonly employed in cancer therapy. Such formulations prolong circulation and minimize toxicity on healthy tissue.

Food Technology: Liposomes are widely used in the food industry to enclose and protect sensitive nutrients, such as vitamins, flavours, and antioxidants. This increases the stability and bioavailability of the active components.

Biotechnology: Biotechnology utilizes liposomes in various applications, particularly for in vitro drug testing and cellular uptake studies. They are often used to study drug transportation and cell membrane interaction processes.

Transdermal Drug Delivery: [56] Transdermal liposomal formulations deliver drugs across the skin surface. This technique bypasses the first-pass effect liver metabolism and enhances drug efficacy.

Personal Care Products: Personal care products, including sunscreens and moisturizers, extensively employ liposomes to improve ingredient performance.

Veterinary Medicine: Liposomes are employed in veterinary medicine to deliver drugs directly to animals, serving similar functions to those they perform in human medicine.

Environmental Decontamination: Liposome technology can be used to decontaminate the environment by facilitating the delivery of substances that can cleanse the contaminated environment.

Intracellular Transport: [57] When conducting research, liposomes can be used as effective vehicles to transport substances to target cells or even specific organelles within the cells.

Nutraceutical Delivery Systems: [51,58] Liposomes are used increasingly in the production of dietary supplements to ensure the optimal absorption of nutraceutical agents.

Wound Healing: The use of liposomes can also extend into wound dressing products to enable the gradual delivery of healing agents.

Current Approaches:

Controlled and Sustained Release: Liposomes are capable of releasing drugs in a sustained and regulated way, which leads to fewer doses and increased patient compliance—a considerable benefit in dealing with chronic diseases.

Vaccines: The potential application of liposomes in vaccine formulation is evident from their ability to increase the stability and efficacy of antigens and facilitate the creation of better vaccines against infectious diseases.

Gene Therapy: Non-viral vectors based on liposomes have proven beneficial as carriers of genetic material, such as siRNA or CRISPR–Cas9 complex, and may provide novel therapies for genetic and hereditary disorders.

Overcoming Biological Barriers: Using various forms of surface modifications, liposomes can be tailored to penetrate certain biological barriers, such as the blood–brain barrier, allowing their targeting to the central nervous system.

Combination Treatments: The ability of liposomes to encapsulate several types of drugs at once enables combination treatments in which chemotherapy and immunotherapy act synergistically in battling cancer.

Further Developments in Liposomal Formulations: Continuous research efforts lead to improvements in terms of stability, drug loading capacity, and reduced cytotoxicity of liposomal preparations.

Regulatory Approvals: More liposomal formulations are expected to be approved following successful trials; hence, the use of liposomes will become increasingly common in the medical sphere.

Future Perspectives in Liposomal Drug Delivery:

Thus, the future of the development of liposomes as carriers of pharmaceutical drugs lies in improving targeting properties, overcoming immune system reactions, and introducing several functionalities into a single liposome. In line with the development of nanomedicine technologies, various innovations appear. First, multi-responsive

liposomes represent the next big step in the development of targeted nanocarriers based on liposomes. These vesicles are designed to react to both external and internal stimuli. Such factors can be pH values, temperature variations, enzymatic activity, redox gradients, magnetism, ultrasound, and others. Using different mechanisms of response for multiple triggers allows for designing multi-responsive liposomes that will be able to deliver a drug in response to specific conditions inside the pathological site in order to provide an efficient treatment while reducing side effects [35]. In addition to mimicking biological systems, modern computational technologies are also gaining momentum. Artificial Intelligence (AI) and machine learning (ML) algorithms are currently used for creating effective and predictive mathematical models of liposomes and their properties. These models are aimed at understanding and predicting the interaction of drug molecules with lipids and the impact of various parameters on vesicle behaviour in vivo. On the other hand, ML could assist in selecting the right targeting ligands, linkers, and surface modifications that would work well with a particular phenotype of the disease. In-silico approaches help to save money and time since fewer materials are required in this case. Modern platforms incorporate AI with microfluidic techniques for precise control of formulations during manufacturing in real time. One interesting area of research is the creation of theragnostic liposomes. As multifunctional vesicles, they combine diagnostic capabilities with delivery functions to enable real-time monitoring of their distribution in vivo and treatment efficiency. They are able to carry fluorophores, MRI contrast agents, radionuclides, or photoacoustic contrast agents inside the vesicle, depending on the application. Theranostic liposomes are especially important in oncology because they allow doctors to develop an individualized approach for each patient, including identification of drug resistance and adjustment of the therapy in accordance with the data collected. For example, doxorubicin-containing liposomes labelled with a near-infrared dye can be used for tumour ablation and visualization during operation. In addition, PET-labelled liposomes help researchers understand drug pharmacokinetics and tumour uptake. [36,37].

CONCLUSION

Liposomes have emerged as a highly promising and versatile drug delivery system in modern pharmaceutical science due to their unique bilayer structure, biocompatibility, and ability to encapsulate both hydrophilic and hydrophobic therapeutic agents. This review comprehensively highlights their classification, composition, preparation methods, physicochemical properties, advantages, limitations, and diverse applications across pharmaceuticals, biotechnology, and related fields. Liposomal systems have demonstrated significant potential in improving drug solubility, stability, bioavailability, and targeted delivery, thereby minimizing systemic toxicity and enhancing therapeutic efficacy. Despite these advantages, certain challenges, such as high production cost, formulation complexity, stability issues, limited drug loading capacity, and regulatory hurdles, continue to restrict their widespread clinical application. Additionally, issues related to large-scale manufacturing and efficient targeting need further optimization. Recent advancements, including surface modification, PEGylation, and the development of stimuli-responsive and multifunctional liposomes, have significantly improved their performance. The integration of emerging technologies such as artificial intelligence, machine learning, and microfluidics is expected to refine liposomal design further and enhance precision in drug delivery. Furthermore, the development of theranostic liposomes offers a promising approach by combining diagnostic and therapeutic capabilities in a single platform.

In conclusion, liposomes represent a crucial advancement in nanomedicine and hold immense potential for future drug delivery applications. Continued research and technological innovations are expected to overcome existing limitations, paving the way for more efficient, targeted, and personalized therapeutic strategies in the coming years.

ABSTRACT

The study in this paper analysed the newspapers reading habits of the Srimad Andavan Arts & Science College (Autonomous) Post Graduate Students and Research Scholars Tiruchirappalli. Structured questionnaires were sent among the PG students and Ph.D research scholars of the college in person and online. Data were gathered on the various aspects of newspaper reading habits including purpose of reading the newspaper, time spent, languages preferred, Most preferred newspaper, Sections of newspaper studied, Sources of newspaper access, Frequency of accessing newspapers. The paper also includes need for newspapers. The Major findings of the study is majority of the users prefers to read Tamil newspapers and prefers to read job opportunities section in the newspapers and most of the respondents accessing newspapers every day.

Keywords: Newspapers, Reading Habits, Sections of newspaper, Need for newspapers

INTRODUCTION

Newspapers began circulating in the 17th century. The first real newspaper in England was printed in 1665. Newspapers became far more common in the late 19th century. In the mid-19th century newspaper reporters began to use the telegraph as a means to get news to their newspapers quickly. Then in 1880 The New York Graphic became the first newspaper to print a photo. In this age of information newspaper is the most powerful tool to express ideas and information. It is a part and parcel of modern life. It is playing its vital role by providing information and creating awareness among the people. It keeps us informed about the current affairs of the whole world. In absence

of newspaper, we cannot have a true picture of our surroundings. It also enhances our knowledge and broadens our vision. It makes us realize that we are living in a dynamic world of knowledge and learning.

Need for Newspapers

- To improve the reading habit of accessing information from various newspapers
- To update the general knowledge and current affairs
- To improve the language skills in English and Regional Language like Tamil
- To prepare for competitive examinations.
- To get information on social and cultural awareness

Newspapers subscribed in Srimad Andavan Arts and Science College Library

- The Hindu
- The Hindu (Tamil)
- Dinamalar
- Dhinamani
- Dhinathanthi
- Dhinakaran
- Time of India
- New Indian Express
- Sudharma (Sanskrit)

REVIEW OF LITERATURE

Sharma, C., & Saini, R. (2019). Newspaper reading habit among the students of University College Kurukshetra: A case study. *Library Philosophy and Practice*, 1-12: The result of this study shows that the college students mainly focus on current affairs, carrier, fashion, sports and business in the newspapers and Majority of respondents read newspapers in Hindi language. Punjab Kesari and Dainik Bhaskar are the most preferred newspaper by the students. The study also states that importance of print version of newspaper has not been diminished due to digitization Dharani, H. (2016). Habit of reading newspaper and preference of print and online newspaper among the college students: A study. *International multidisciplinary Research Journal*, *4*(3), 30-38: This study reveals that most of the students prefer online newspaper because of quick updation and free access. This study also explored the reading habit of the college students. The majority of the respondents prefer The Hindu newspaper to read. Followed by Dinamalar and Dhinathanthi.

Munniammal K, Newspaper Reading Habits of Rural and Urban Students in Madurai Kamaraj University Constituent College Sattur (Reaching the unreached: Proceedings of the TEQIP II sponsored national conference on connecting the library users and resources through innovative services and technologies, August 2014): Reading habit of rural and urban college students of the Madurai Kamaraj University constituent college Sattur is higher among urban students than rural counterparts. The need is to bridge the gap in reading culture betwwen regiions for developing a great nation. The goal can only be achieved through different means; however the education for all and information for all are the two main pillars of reading society that need more emphasis. Devendra Kumar, Newspaper Reading Habits of University Students: A Case Study of Chaudhary Charan Singh University, India (Library Philosophy and Practice (e-journal),2011) : Library users read newspaper to get the latest information about what is happening around. Newspapers are responsible for creating and generating reading habits among university students. Newspapers are essential for university students, but due to the enormous explosion of information published in the form of newspapers in different languages in particular, it is impossible for libraries to subscribe all that are published at the national and international levels. Under these circumstances the best way of serving the users is by proper display of newspapers and notifying users about new information related to education. In library there should be adequate newspapers to accelerate reading habits.

Objectives of the Study

- To identify the preferred language of the users to read the newspapers
- To analyze the sources used to read the newspapers
- To know how much time used to spend reading the newspapers
- To know the frequency of reading the newspapers
- To analyze which sections are read most by the students
- To know which newspaper is mostly read by the students
- To know the purpose of newspaper reading

METHODOLOGY

The researcher prepared a structured questionnaire for the primary data collection. A total of 110 questionnaires were distributed. The questionnaire was distributed the to the PG students during class time and the research scholars during their presence in the library. The respondents were given 10 to 15 minutes timing to fill the questionnaire and collected back. The main criteria to select the sample is the particular respondent should have habit of reading newspapers. Out of the 110 questionnaires, only 98 questionnaires were filled properly and considered as valid. Multiple responses questions were given for the criterias Sources for Newspaper access, Sections of newspapers mostly read, Most preferred newspaper and purpose of reading newspapers. The data collection has taken around 3 weeks to get finished. The user population was defined as PG students, and Research Scholars of Srimad Andavan Arts and Science College (Autonomous), Tiruchirapalli,

Data Analysis and Interpretation

The collected data were analysed by using statistical method and tabulated with percentage. The data analysis are given below.

Findings

- Most of the students are male and most of them are PG students.
- Most of the respondents preferred Tamil language newspapers for reading.
- Majority of respondents using the college library to access newspapers and most of them spending less than an hour to read the newspapers.
- Majority of the respondents accessing the newspapers everyday
- Major numbers of students prefers to read job opportunities section in the newspapers.
- Most of the users wants to read the Tamil Newspaper Dhinathanthi.
- Most of the respondents reads the newspapers to get information only.

Scope of this study

Some of the major scope of this study are

- The study identified preferred language of users to read the newspapers and the various sources used by the respondents to access newspapers, and
- The study also indicates the sections of news mostly read by the users, purpose of reading newspaper and mostly preferred newspaper by the respondents.

Limitations of this study

- The study is limited to Post Graduate students and Research Scholars of Srimad Andavan Arts and Science College
- Limited Sample Size
- This study covers the newspaper reading habit of students during the particular period

- This study not focused about family background, digital literacy and access of electronic newspapers by the respondents.

CONCLUSION

Newspapers continues to be one of the major source in dissemination of information even in today's Information and Communication Technology (ICT) era. In the present era students and scholars access newspapers in both printed and online formats. This study is undertaken to examine the Newspaper Reading Habits among Postgraduate Students and Research Scholars of Srimad Andavan Arts & Science College (Autonomous), Tiruchirappalli. The study indicates that newspapers are continues to be a relevant source among the academic community to access career opportunities, political development, general awareness..etc. The study reveals that Tamil is the preferred language by the respondents in newspaper reading, and it indicates comfortable medium of language to access newspapers. The findings of this study suggests that language and preferred newspapers are the important factors to be considered in a library to subscribe the newspapers. The study elucidates that the college library continues to play an important role in providing access to career information, General Knowledge and political development. In conclusion, this study suggests that newspaper reading remains a meaningful information seeking habit and post graduate students and research scholars of Srimad Andavan Arts and Science College. For future research the college should preserve the important newspaper clippings on general news and career information.

Table 1 Gender Wise Distribution

S.No	Description	Number of respondents	Percentage
1	Male	74	75.5
2	Female	24	24.5

The table shows high responses (75.5%) is from male candidates

Table 2: **Sample wise Distribution**

S.No	Class	Number of respondents	Percentage
1	PG	72	73.4
2	Ph.D	26	26.6

The table shows that the distribution of respondents by class wise. Out of the 98 respondents, PG students are 72 (73.4%), and Ph.D Scholars are 26 (26.6%) and the highest respondents are PG Students.

Table 3: **Preferred Language Distribution**

S.No	Language Preferred	No.of Respondents	Percentage
1	Tamil	58	59.1%
2	English	33	33.6%
3	Both	07	07.1%

The above table shows that 59.1% of students prefers to read Tamil language newspapers, 33.6% of students prefers English language newspapers and 07.1% of them uses both the languages. Most of the respondents read Tamil newspapers only.

Table 4: **Sources for Newspaper access**

S.No	Source	No.of Respondents	Percentage
1	Individual subscription at home	36	36.7%
2	College Library	41	41.8%
3	Public Library	27	27.5%
4	Online access	17	17.3%

The table shows that College Library is the most common source used to access the newspapers.

Table 5: **Time spent in reading newspapers**

S.No	Description	Number of Respondents	Percentage
1	Less than an hour	53	60.2%
2	1 to 2 hours	22	22.44%
3	More than 2 hours	23	23.46%

The table shows that most of the students (60.2%) spends less than an hour to read the newspapers

Table 6: **Frequency to access the newspapers**

S.No	Description	Number of Respondents	Percentage
1	Daily	45	45.91%
2	Once in 3 days	28	28.57%
3	Once in a week	14	14.28%
4	As and When	11	11.22%

The table shows that most of the students (45.91%) reads the newspapers daily

Table 7: **Sections of newspapers mostly read**

S.No	Description	Number of Respondents	Percentage
1	Job Opportunities	81	82.65%
2	Advertisements	74	75.51%
3	General News	58	59.18%
4	Politics	53	54.08%
5	Sports	53	54.08%
6	Cinema	40	40.81%

The table shows that most of the students (82.65%) prefers to read job opportunities news in the newspapers.

Table 8: **Most preferred newspaper**

S.No	Description	Number of Respondents	Percentage
1	Dhinathanthi	78	79.59%
2	The Hindu (English)	57	58.16%
3	The Hindu (Tamil)	47	47.95%
4	Dhinamani	26	26.53%

5	Dhinamalar	31	31.63%
6	Dhinakaran	26	26.53%
7	New Indian Express	08	08.16%
8	Times of India	10	10.20%
9	Sudharma	06	06.12%

The table shows that most of the students (79.59%) prefers to read Dhinathanthi newspaper.

Table 9: **Purpose of reading the newspapers**

S.No	Description	Number of Respondents	Percentage
1	To get the information	63	64.28%
2	To develop general knowledge	48	48.97%
3	Recreation	17	17.34%

The table reveals that majority of the respondents (64.28%) reads the newspapers to get information.

ABSTRACT

Smartphone sensors offer a practical way to track your location indoors where GPS fails, but they suffer from a major flaw known as ”sensor drift,” where tiny tracking errors add up over time and cause the system to lose your actual position. To fix this, we developed a new AI-powered system that tackles drift using three integrated tools: a filter that cleans up messy raw sensor data, a smart tracker that maps your path while ensuring it makes sense within a real-world floor plan, and a confidence checker that calculates exactly how sure the system is about your location at any given time. By teaching the AI basic physics and training it to recognize both sudden movements and long-term walking trends, the system actively rejects impossible movements and only maps realistic human paths. When tested across 15 different smart phones of varying quality, the framework proved highly accurate, drifting by only 4.2 percent—missing the exact location by less than a meter—over a 70-meter walk, outperforming current top-tier tracking methods. Ultimately, com-pared to using uncorrected sensor data, our AI reduced direction-facing errors by 85 percent and overall location errors by nearly 90 percent, providing a highly reli-able and extensively tested solution for indoor navigation regardless of the device’s hardware quality.

Keywords: Inertial Localization, Generative Adversarial Networks, IMU, Sen-sor Fusion, Uncertainty Estimation, Deep Learning

INTRODUCTION

Indoor localization has gained significant attention due to its wide range of applica-tions in navigation, healthcare monitoring, emergency response, and robotics [1]. Building structures attenuate and reflect satellite signals, rendering GPS useless inside buildings, despite the fact that Global Navigation Satellite Systems provide accurate positioning outdoors. Wi-Fi and Bluetooth-based infrastructure-dependent approaches require dense deployment, whereas LiDAR and camera-based approaches require well-lit, feature-rich environments and are expensive to scale [2]. Because they are widely available on smartphones, do not require a line of sight, function reliably in a variety of environments, and are energy and computation efficient, inertial measurement units present a promising alternative [3]. However, IMU-based localization faces a fundamental obstacle: sensor drift. Bias and noise build up quickly through double integration in accelerometer and gyroscope measurements. Traditional Strap-down Inertial Navigation Systems can accumulate trajectory errors of hundreds of meters within minutes of operation [4]. Inertial localization has been significantly improved by deep learning. One level of integration is eliminated by architectures like IONet [5] and RoNIN [6] that estimate velocity changes directly from raw inertial data. Unmodeled uncertainties, sensor biases across devices, and the absence of explicit spatial constraints [7] remain limitations of these methods.

The solution presented by generative adversarial networks is compelling. Recent works includ-ing UMLoc [8] demonstrate map-constrained trajectory generation with drift ratios of 5.9%, while SDG-GAN [9] achieves signal enhancement with 82.69% reduction in attitude error.
Despite these advances, existing methods suffer from three critical limitations:

- separation of signal enhancement and trajectory generation,
- lack of physics-informed constraints, and
- insufficient cross-device generalization.

This paper proposes a novel unified GAN-based framework that addresses these limitations through three integrated components: a signal enhancement module with multi-scale attention, a physics-informed trajectory generation module with map constraints, and an uncertainty quantification module. The key contributions are:

- A unified end-to-end GAN framework that jointly performs signal enhancement, trajectory generation, and uncertainty quantification
- A novel physics-informed loss function incorporating kinematic constraints including velocity continuity and acceleration bounds
- A multi-scale attention mechanism for robust cross-device signal enhancement
- Comprehensive experimental validation on 15 smartphones demonstrating state-of-the-art performance with 4.2% drift ratio and 0.98m ATE

RELATED WORK

Classical Inertial Navigation

Strap down Inertial Navigation Systems (SINS), which carry out double integration of acceleration measurements, are the foundation of traditional IMU-based localization. The fundamental limi-tation is error accumulation, where small biases grow quadratically with time [10]. Zero-Velocity Update (ZUPT) methods reset velocity errors using foot-mounted IMU stance phases to achieve a distance error of 1 to 1.5% [11]. Continuous integration is avoided by Pedestrian Dead Reckoning (PDR), which estimates step length and detects steps [12]. However, specific sensor placements and assumptions regarding gait patterns are required for these methods.

Deep Learning for Inertial Localization

Inertial localization has been completely rewritten by deep learning. IONet [5] uses bidirectional LSTM to estimate velocity changes from raw IMU data. RoNIN [6] introduced robust velocity loss functions and investigated multiple

architectures. TLIO [13] combines learning with classical filtering. IDOL [14] addresses orientation estimation. RNIN-VIO [15] integrates neural inertial navigation with visual-inertial odometry.
Despite these advances, deep learning methods struggle with uncertainty quantification and cross-device generalization. Recent work has explored uncertainty-aware approaches [16] and self-supervised learning [17].

GAN-Based Approaches
GANs have emerged as powerful tools for inertial localization. For map-constrained trajectory generation, UMLoc [8] employs a conditional GAN with cross-attention, achieving 5.9% drift and 1.36m ATE. Scale and direction guidance are used in SDG-GAN [9] to improve the signal and reduce attitude error from 10.69° to 1.85°. With adaptive sensor weighting, GANs are applied to visual-inertial odometry by XIRVIO [18]. GANP [19] uses uncertainty quantification to generate pseudo-GNSS measurements. UAV localization error is reduced by 30.3% using WGAN and pseudo fingerprint maps [20].

PROPOSED METHODOLOGY

Problem Formulation
Given a sequence of IMU measurements $X_{1:T} = \{(a_t, \omega_t, m_t)\}^T$ where $a_t \in R^3$ is acceleration, $\omega_t \in R^3$ is angular velocity, and $m_t \in R^3$ is magnetometer reading, the goal is to estimate the trajectory $P_{1:T} = \{p_t\}^T$ with associated uncertainty bounds. The proposed framework learns a mapping $f : X_{1:T} (P_{1:T}, \Sigma_{1:T})$ where $\Sigma_{1:T}$ are uncertainty estimates at each time step.

Overall Architecture
The proposed framework consists of three integrated modules as shown in Figure 1:

1. Multi-Scale Signal Enhancement Module: Denoises raw IMU signals using a multi-scale attention mechanism
2. Physics-Informed Trajectory Generation Module: Generates trajectories with kinematic constraints using a conditional GAN
3. Uncertainty Quantification Module: Provides calibrated prediction intervals

Multi-Scale Signal Enhancement Module
The signal enhancement module employs a multi-scale attention mechanism that operates at different temporal resolutions to capture both short-term noise patterns and long-term signal characteristics.

Multi-Scale Feature Extraction
Given raw IMU signal X, we apply multiple convolutional branches with different kernel sizes:
$h_s = \text{Conv}_{k_s}(X), s \in \{1, 2, 3, 4\}$ (1)
where k_s 3, 7, 15, 31, captures features at different temporal scales. Each branch includes batch normalization and ReLU activation.

Cross-Scale Attention
A cross-scale attention mechanism learns to weight features from different scales:
$\alpha_s = \text{Softmax}(\text{MLP}(h_s) \cdot \text{MLP}(h_1)^T / \sqrt{d})$ (2)
$h_{\text{fused}} = \sum_{s=1} \alpha_s h_s$ (3)
This attention mechanism enables the network to adaptively focus on scales most relevant for signal reconstruction.

Enhancement Network
The enhanced signal is generated through an encoder-decoder architecture:
$\hat{X} = \text{Decoder}(\text{Encoder}(h_{\text{fused}}))$ (4)

The enhancement network is trained adversarially with a discriminator that distin-guishes enhanced signals from clean reference signals.

Physics-Informed Trajectory Generation Module

The trajectory generation module employs a conditional GAN with physics-informed con-straints.

Conditional Generator

The generator G takes enhanced signal $X^{\cdot}$ and map information M as input:

$P^{\cdot} = G(X^{\cdot}, M ; \theta_G)$ (5)

The generator employs a transformer architecture with cross-attention between sensor features and map features.

Physics-Informed Loss

Three physics-informed loss components enforce kinematic consistency:

Velocity Continuity Loss: Enforces smooth velocity transitions:

where $v_t = p_t - p_{t-1}$.

$L_{vel} = \Sigma$

t=2

$vt - vt-1\ ^2$ (6)

Acceleration Bounds Loss: Prevents physically impossible accelerations:

$L_{acc} = \Sigma \max(0, a_t\ _2 - a_{max})^2$ (7)

t=3

Map Compliance Loss: Ensures trajectories respect environmental boundaries:

$L_{map} = \Sigma \max(0, \text{dist}(p_t, O) - \epsilon)$ (8)

t=1

where represents obstacle regions and ϵ is a safety margin. The total generator loss is:

$LG = Ladv + \lambda 1 Lvel + \lambda 2 Lacc + \lambda 3 Lmap + \lambda 4 Ltraj$ (9)

where $L_{traj} = P^{\cdot} - P_{gt}\ ^2$ is the supervised trajectory loss.

Discriminator

The discriminator D is trained to distinguish generated trajectories from ground-truth trajectories:

$L_D = -E_{P\sim pdata}[\log D(P)] - E_{P\hat{}\sim p}[\log(1 - D(P^{\cdot}))]$ (10)

Uncertainty Quantification Module

Uncertainty quantification employs a quantile regression approach similar to UMLoc [8] but with two key innovations.

Adaptive Quantile Regression

The quantile regression module uses an LSTM with adaptive parameters that adjust based on signal quality:

$(q\hat{}^L, q\hat{}^U) = \text{LSTM}_\phi(X^{\cdot}t, \sigma_t)$ (11)

tt where σ_t is a signal quality estimate from the enhancement module.

Uncertainty Propagation

Uncertainties are propagated through the trajectory generation using Monte Carlo dropout:

$P^{\cdot(i)} = G(X^{\cdot}, M, \text{Dropout}^{(i)}), \quad i = 1, \ldots, N$ (12)

Prediction intervals are constructed from the empirical distribution of $\{P^{\cdot(i)}\}^N$.

Experimental Setup

Dataset Collection

We collected a comprehensive dataset using 15 smartphones with diverse IMU specifica-tions:
Data was collected in three indoor environments:

- Office building (500m², 3 floors)
- Shopping mall (2000m², 2 floors)
- Hospital corridor (300m, 1 floor)

Ground truth was obtained using a motion capture system (Vicon, accuracy 1mm) and a laser scanner (accuracy 2cm). Total dataset size: 15 hours of walking data with diverse motion patterns.

Evaluation Metrics

- Absolute Trajectory Error (ATE): RMSE between estimated and ground-truth trajectories
- Drift Ratio: ATE divided by total travel distance
- Attitude Error: Mean angular deviation from ground-truth orientation
- Position Error: RMSE of displacement estimates
- Semantic Recognition Accuracy: Classification of motion patterns
- Trajectory FSSE: Frechet Spline Sliding Error for morphological similarity
- Uncertainty Calibration: Coverage rate vs. nominal confidence level

Implementation Details

The network was implemented in PyTorch with the following specifications:

- Generator: 6 transformer layers, 8 attention heads, 512 hidden dimension
- Discriminator: 4-layer MLP with spectral normalization
- Optimizer: Adam with learning rate 0.0001, $\beta_1 = 0.5$, $\beta_2 = 0.999$
- Training: Batch size 64, 100 epochs, curriculum learning
- Hardware: NVIDIA A100 GPU (40GB)

RESULTS AND ANALYSIS

Overall Performance

Table 3 presents the overall performance comparison with state-of-the-art methods.

Signal Enhancement Performance

The proposed multi-scale attention mechanism achieves significant improvements across all signal quality metrics.

- 85.3% reduction in attitude error (from 10.69° to 1.57°)
- 89.7% reduction in position error (from 1.09m to 0.112m)
- 22.8% improvement in semantic recognition accuracy (from 78.42% to 96.31%)
- 95.0% improvement in trajectory FSSE (from 0.78 to 0.0387)

Physics-Informed Loss Ablation

Ablation studies validate the contribution of each physics-informed loss component.

Uncertainty Calibration

The proposed framework achieves near-perfect uncertainty calibration, matching or ex-ceeding UMLoc's calibration performance. The adaptive quantile regression with signal quality estimates enables better uncertainty quantification in challenging scenarios.

Cross-Device Generalization

To evaluate cross-device generalization, we trained models on one device (HUAWEI Mate30 Pro) and tested on all others. The framework demonstrates robust generalization with average ATE of 1.07m across all devices, only 9.2% degradation from the training device (0.98m). This is attributed to the multi-scale attention mechanism that adapts to different sensor characteristics our framework achieves competitive computational efficiency, making it suitable for real-time deployment on resource-constrained devices.

DISCUSSION AND CONCLUSION

The proposed framework outperforms existing methods across all metrics:

- 27.9% improvement in ATE over UMLoc (0.98m vs. 1.36m)
- 28.8% improvement in drift ratio (4.2% vs. 5.9%)
- 15.1% improvement in attitude error over SDG-GAN (1.57° vs. 1.85°)
- 20.0% improvement in position error (0.112m vs. 0.140m)

The improvements stem from three key innovations:

Unified Architecture: Joint training of signal enhancement and trajectory genera-tion enables better information flow and prevents error accumulation.

Physics-Informed Loss: The kinematic constraints enforce physically plausible tra-jectories, reducing drift and improving long-term accuracy.

Multi-Scale Attention: Adaptive feature extraction across temporal scales enables robust performance across diverse sensor hardware.

Despite strong performance, several limitations remain:

- Map Dependency: The framework requires floor-plan maps for the map compli-ance loss, limiting applicability in unmapped environments
- Training Data: The model requires diverse training data covering various envi-ronments and motion patterns
- Computational Cost: While efficient, real-time deployment on low-power embed-ded systems requires further optimization

Future work will focus on:

- Developing self-supervised learning techniques to reduce dependency on labeled data
- Exploring map-free localization using learned environmental representations
- Optimizing the framework for real-time deployment on edge devices
- Extending the approach to 3D indoor localization and multi-floor environments

In summary, we introduced a smart AI framework that solves the persistent problem of indoor sensor drift by combining three key features: cleaning up noisy sensor signals, mapping realistic walking paths using basic physics, and calculating real-time confidence scores. By keeping movements realistic and filtering out background noise, the system achieves industry-leading accuracy, drifting by just 4.2 percent and staying within less than a meter of the true location over a 70-meter walk. This comfortably outperforms existing state-of-the-art methods like UMLoc and SDG-GAN. Because the system adapts seamlessly across different smartphones and provides reliable estimates of its own location confidence, it offers a practical, real-world solution for reliable indoor navigation where GPS falls short.

ABSTRACT

To design an automatic diagnosis system to identify the early stage of Periodontitis bone and classification from panoramic dental radiographs using neural network algorithm, which helps for periodontitis treatment. This study has suggested BoneFormerNet as a novel model that combines the convolutional neural network for feature extraction along with Vision Transformer to leverage global context information using panoramic radiographs. Multi-scale feature fusion, attention-driven learning, and adaptive classification layers have been considered to enhance the discrimination of features and their effective classification. This study is conducted on the publicly accessible GitHub Automatic Panoramic Radiograph Periodontitis Bone Loss Diagnosis dataset that consists of images pertaining to periodontal bone loss. Experimental evaluation demonstrates superior classification performance, achieving an accuracy of 98.91%, precision of 97.83%, recall of 97.83%, F1-score of 97.83%, and an AUC value of 98.55%. This research devices a novel approach of integrating CNN-based local feature extraction with transformer-based global representation learning for the creation of BoneFormerNet, which provides a robust and efficient framework for automated periodontitis bone classification from panoramic dental radiographs.

Keywords: Periodontitis, Alveolar Bone Loss, BoneFormerNet, Vision Transformer, Panoramic Radiographs

INTRODUCTION

A deep learning framework for precise and efficient dental disease diagnosis in OPG radiographs using self-attention was presented in [1], where Vision Transformer (ViT) and Swin Transformer architectures were employed to classify periodontal disease stages through preprocessing, ROI extraction, and self-attention-based feature learning. Sclerostin modulation and bone resorption in apical periodontitis were investigated in [2] using ELISA-based quantification of sclerostin and correlation analysis with inflammatory biomarkers, including RANKL, MMP-9, and PGE-2. Automated periodontal bone loss classification from panoramic radiographs was proposed in [3] using CNN architectures such as InceptionV3, InceptionV4, and ResNet-50 following image preprocessing and augmentation. A Dual-Embedding Few-Shot Learning (DE-FSL) framework, named DualFit, was introduced in [4], combining Sentence Transformer and SetFit embeddings with contrastive learning and adaptive fusion for periodontal bone loss classification. The immunodiagnostic potential of the RANK/RANKL/OPG ratio in gingival crevicular fluid was evaluated in [5] through ELISA-based biomarker quantification and statistical analysis. An automated framework integrating U-Net segmentation with YOLO-v9 for alveolar bone loss measurement and periodontitis stage prediction was presented in [6]. DentifyNet, a Faster R-CNN-based architecture incorporating ResNet-50 and Feature Pyramid Network (FPN), was developed in [7] to improve multi-scale tooth detection and numbering in panoramic radiographs.

A CGRP-loaded ROS-responsive hydrogel system promoting neuro-angiogenic signalling and alveolar bone regeneration in diabetes-associated periodontitis was reported in [8]. A comprehensive PRISMA-DTA-based systematic review of artificial intelligence algorithms for dento-maxillofacial radiograph-based age estimation was conducted in [9]. Radiographic periodontal diagnosis and the underlying mechanisms of alveolar bone destruction mediated through the RANK–RANKL–OPG pathway and associated signalling cascades, including NF-κB, MAPK, JAK/STAT, and PI3K/Akt, were comprehensively reviewed in [10]. Convolutional neural networks, Vision Transformers, U-Net segmentation, object identification networks, few-shot learning, and hybrid deep learning models have improved panoramic dental radiograph-based periodontitis diagnosis references from (2024–2026). These methods have improved periodontal bone loss diagnosis, although significant technical issues remain. CNN-based models learn local trabecular bone textures but not long-range anatomical correlations across the radiograph, confusing neighbouring disease stages. Vision Transformer models accurately mimic broad contextual information but frequently miss small bone changes and fine structural features needed for early diagnosis. Instead of robust stage-wise illness categorisation, segmentation and detection methods identify anatomical areas. Few-shot learning approaches have limited training samples and poor generalisation, whereas most hybrid architectures concatenate CNN and transformer features without using their complimentary information. Many published techniques have been assessed using tiny datasets and lack appropriate local-global representation integration mechanisms. BoneFormerNet uses a CNN–Vision Transformer architecture with attention-guided feature fusion to learn discriminative local bone textures and global anatomical relationships to fill these research gaps. The proposed framework adaptively integrates complementary feature representations, reduces inter-stage misclassification, improves early and advanced periodontal bone loss discrimination, and strengthens panoramic dental radiograph-based automated periodontitis bone classification.

METHODS AND MATERIALS

This work has developed BoneFormerNet, a hybrid deep learning architecture, accurately classifies periodontal bone loss severity from dental radiographs. Alveolar bone degeneration, apparent in panoramic and periapical radiographs as marginal bone loss, lower bone density, and uneven bone crest structures, drives periodontitis development. Radiographs frequently include noise, overlapping anatomical components, uneven lighting, and minor bone alterations that make manual categorization of bone loss phases difficult. Dental radiographs are fed into BoneFormerNet's automated pipeline to forecast periodontal bone stage. After radiograph acquisition, preprocessing,

feature learning, CNN–ViT fusion, and classification follow. The approach produces a multi-class probability distribution of bone loss stages for organized and clinically relevant severity evaluation. The framework is composed of four major modules: (i) radiograph preprocessing, (ii) CNN-based local feature extraction, (iii) transformer-based global contextual modelling, and (iv) hybrid fusion-based classification. This combination ensures that both micro-level texture patterns and macro-level bone distribution changes are captured effectively.

Figure 1 shows the BoneFormerNet model's approach for classifying periodontal bone loss from dental radiographs. OPG or periapical X-ray images are pre-processed by shrinking, normalizing, noise reduction, and contrast enhancement to increase bone border visibility. Localizing and cropping the bone-related ROI removes extraneous background areas after preprocessing. The framework parallelizes feature extraction with two branches. The Vision Transformer encoder models long-range radiograph dependencies to learn global contextual representations, while the CNN encoder captures local bone texture characteristics including trabecular density variations and marginal bone abnormalities. A cross-stream attention-based fusion module integrates local and global bone properties from extracted data. Global feature consolidation reduces redundancy and highlights discriminative patterns after fusion. Final stage classification output comes from completely linked prediction blocks. The findings of preprocessing and dual feature extraction increase bone structure representation, feature separability, and periodontitis severity stage classification. BoneFormerNet stands out because of its ability to extract minute features of bone texture and distant radiographic relationship patterns at the same time. Conventional deep learning models based on CNN architecture focus more on bone edges and textural gradient features, which cannot possibly capture dispersed bone loss problems. The architecture based on transformers may be able to mimic distant relations but loses the subtle features of trabecular bone required for early diagnosis. Therefore, BoneFormerNet combines both streams as follows:

- The **CNN branch** captures high-frequency local patterns such as trabecular structure, bone crest erosion, and periodontal ligament widening indicators.
- The **Vision Transformer (ViT) branch** captures global anatomical context by modelling interactions across multiple radiographic patches, allowing the model to understand broader bone loss distribution.

Attention-based fusion technique in BoneFormerNet allows for adaptive weighting of CNN and ViT embeddings, which is not common to existing hybrid methods using feature concatenation. This makes sure that all the discriminative properties of each stage are included in the final representation. It is novel because it learns local evidence and global trends together to address periodontal bone condition severity. The initial step of the process is to take dental x-rays (panoramic or periapical). Let the input radiograph be represented by:

$$R \in \mathbb{R}^{H \times W} \qquad (1)$$

where H and W represent the height and width of the radiograph. Radiographs might be of varied resolutions; hence, scaling is undertaken for consistent size of model input. The resized radiograph is shown as:

$$R_s = \Psi(R) \qquad (2)$$

where $\Psi(\cdot)$ represents the resizing operator. To improve intensity consistency across samples, intensity scaling is applied. If R_s^{max} and R_s^{min} represent the maximum and minimum pixel values, the normalised radiograph is defined as:

$$R_n(i,j) = \frac{R_s(i,j) - R_s^{min}}{R_s^{max} - R_s^{min} + \epsilon} \qquad (3)$$

where ϵ is a small constant to prevent division instability. Dental radiographs are also noisy because of the scanning variance and acquisition settings. High-frequency artefacts are reduced by using a smoothing filter. The filtered radiograph was composed as:

$$R_f = R_n * K \qquad (4)$$

where $*$ denotes convolution and K represents a smoothing kernel. The contrast enhancement is used to emphasise the borders of the bone. Adaptive improvement increases marginal bone transparency by increasing local intensity differences. The boosted output is given as:

$$R_e = \Gamma(R_f) \quad (5)$$

where $\Gamma(\cdot)$ denotes contrast enhancement transformation. It is a form of learning that guarantees convergence without any issues of overfitting. Table 1 below illustrates the main software packages and their respective versions that are used in constructing the suggested deep learning model. TensorFlow-GPU and Keras help in the training and architecture design of machine learning models, whereas NumPy does computations. Pillow and OpenCV help improve images. Tqdm can be used to monitor training steps.

RESULTS AND DISCUSSION

The Periodontitis Disease dataset, which is available on Kaggle (https://www.kaggle.com/muflihsan/periodontitis-disease), consists of dental radiography images used to automatically analyze periodontal diseases. In this case, the dataset consisted of dental X-ray images focusing on the structures of teeth, gingiva, and alveolar bones, which are key components in diagnosing bone loss due to periodontal disease. The images were sorted into class-based folders to allow for supervised learning in detecting and classifying periodontitis [21]. Image-level labeling was performed using data labels depending on the conditions of periodontal disease and thus allowing for classification using CNN. Bounding box annotation or pixel-level annotation is not included in this dataset; hence, it is used primarily for classification rather than segmentation. Due to variation in quality and illumination among the images, several image preprocessing techniques that are standard in deep learning, including resizing, normalization, contrast adjustment, and denoising, have been used to enhance images prior to training. This database can be used in studies involving the detection of periodontal diseases using dental X-ray images. Image augmentation is performed for achieving higher accuracy. For an overall image of 3924, a split ratio of 70:30 was achieved. Training involved 2747 images while testing involved 1177 images

Figure 2 depicts morphological variation in terms of jaws, tooth arrangement, and alveolar bone condition. Variation in terms of contrasts, brightness levels, and noise are also evident depending on the changing imaging parameters. The radiographs point out several difficulties including overlapping bones and indistinct bone margins. Therefore, the use of proper preprocessing and feature extraction becomes crucial in the process of classifying periodontal bone stages accurately. Figure 3 shows that the CNN model correctly classified 40 Stage I, 42 Stage II, 44 Stage III, and 46 Stage IV radiographs, demonstrating effective learning of local trabecular bone textures and marginal bone characteristics. However, 3 Stage I samples were misclassified as Stage IV and 2 Stage I samples as Stage III, indicating that convolutional feature extraction alone cannot adequately capture long-range anatomical dependencies across panoramic radiographs. Similar limitations were reported in CNN-based periodontal bone loss classification using InceptionV3, InceptionV4, and ResNet-50 architectures [3], where reliance on local receptive fields reduced discrimination between neighbouring disease stages. In contrast, BoneFormerNet integrates transformer-based global contextual learning with CNN feature extraction, reducing inter-stage confusion and improving the overall classification performance to 98.91% accuracy, compared with 96.77% reported for the CNN-based ResNet-50 model [3]. This demonstrates that combining local and global feature representations significantly enhances the robustness of periodontal bone stage classification.

Figure 4 shows that the Vision Transformer (ViT) correctly classified 44 Stage I, 43 Stage II, 45 Stage III, and 42 Stage IV radiographs, demonstrating improved learning of global anatomical relationships through the self-attention mechanism. Most misclassifications were confined to neighboring disease stages, indicating effective contextual representation with limited distant-stage confusion. Similar findings were reported by [1], where ViT and Swin Transformer architectures improved periodontal disease classification by modelling long-range dependencies in panoramic radiographs. Transformer-based models remain less effective in preserving subtle trabecular bone textures and marginal bone irregularities required for early-stage diagnosis. BoneFormerNet addresses this limitation by integrating CNN-based local feature extraction with transformer-based global contextual learning, enabling

complementary feature representation that reduces inter-stage confusion and improves the overall classification performance to 98.91% accuracy, compared with 96.00% reported for the ViT–Swin Transformer framework in [1]. These findings demonstrate that combining local structural information with global contextual modelling provides superior diagnostic performance over a standalone Vision Transformer architecture.

Figure 5 shows that the proposed BoneFormerNet correctly classified 45 Stage I, 44 Stage II, 45 Stage III, and 46 Stage IV radiographs, producing the highest number of correct predictions with only a few neighboring-stage misclassifications. Unlike CNN-based models that primarily learn local trabecular textures and cortical boundaries [3] or Vision Transformer models that focus on global contextual relationships [1], BoneFormerNet simultaneously captures both complementary feature representations through an attention-guided CNN–ViT fusion mechanism. Furthermore, U-Net with YOLO-v9-based approaches mainly emphasize bone segmentation and measurement for stage prediction rather than comprehensive feature representation [6], while DentifyNet is designed for multi-scale tooth detection and numbering instead of periodontal bone loss classification [7]. By adaptively integrating discriminative local textures with long-range anatomical dependencies, BoneFormerNet substantially reduces inter-stage confusion and achieves an overall classification accuracy of 98.91%, outperforming the CNN-based ResNet-50 (96.77%) [3], ViT–Swin Transformer (96.00%) [1], and YOLO-v9 (89.00%) [6] while providing a task-specific framework beyond the detection capabilities of DentifyNet [7]. These findings demonstrate that attention-guided fusion of local and global feature representations improves feature discrimination, robustness, and generalization for automated periodontal bone stage classification.

The assessment measures for evaluating the performance of the proposed BoneFormerNet have been presented in Table 2 below. Accuracy represents the overall correctness of predictions made by the model while precision and recall represent reliability on detecting diseases. The F1-Score is the balance between the two measures. On the other hand, specificity measures whether there are any correct predictions made for no disease. Figure 6 demonstrates ROC curves of the CNN brain tumor classification model for four different classes. The model has excellent discriminatory power with AUC values of 0.9275, 0.9493, 0.9674, and 0.9819 for Class 1, Class 2, Class 3, and Class 4, respectively, giving an average AUC of 0.9565. The ROC curve does not fall below the baseline at any point. The ROC curves based on ViT for four types of tumours are depicted in the Figure 7. The results show the classifier has impressive classification ability, as seen from the high AUCs of 0.9607, 0.9601, 0.9782, and 0.9701 for Classes 1, 2, 3, and 4 respectively, leading to an average AUC of 0.9673. This is evident from the fact that the ROC curves are above the diagonal line. Figure 8 represents the ROC curves of the hybrid CNN-ViTs network for four different tumour classes. This network is a discriminating model because it has achieved AUC scores of 0.9855 for Class 1, 0.9746 for Class 2, 0.9855 for Class 3, and 0.9964 for Class 4, which resulted in a mean AUC score of 0.9855. These ROC curves are very far from the dotted line, suggesting that the model performs well in classifying the data.

Figure 9 compares BoneFormerNet with recent state-of-the-art methods using accuracy, precision, recall, and F1-score. BoneFormerNet achieved an accuracy of 98.91%, precision of 97.83%, recall of 97.83%, and F1-score of 97.83%, outperforming the ViT–Swin Transformer (96.00% accuracy) [1], ResNet-50 (96.77% accuracy) [3], and YOLO-v9 (89.00% accuracy) [6]. Although the DualFit framework reported slightly higher numerical values using BioBERT, ClinicalBERT, and PubMedBERT embeddings [4], it performs classification on textual radiographic reports rather than directly analysing panoramic dental images, making a direct comparison inappropriate. The improved performance of BoneFormerNet is primarily attributed to its hybrid architecture, where the CNN branch effectively extracts fine-grained trabecular bone textures, cortical boundaries, and marginal bone changes, while the Vision Transformer captures long-range anatomical dependencies through self-attention. Unlike the CNN-based approach in [3], which is restricted to local feature extraction, or the transformer-based framework in [1], which may overlook subtle structural variations, BoneFormerNet adaptively fuses both representations using an attention-guided feature fusion module. Furthermore, methods based on U-Net and YOLO-v9 [6] mainly focus on bone segmentation and measurement, whereas DentifyNet [7] is optimized for tooth detection and numbering rather than periodontal bone stage classification. By jointly learning complementary local and global representations, BoneFormerNet minimizes redundancy, reduces inter-stage confusion, enhances discrimination between early and advanced disease stages, and

provides superior robustness under variations in bone morphology, image contrast, and anatomical complexity. These architectural advantages explain the consistent improvement observed across all performance metrics compared with existing image-based periodontal diagnostic frameworks.

The experimental results consistently demonstrate that BoneFormerNet achieves superior stage-wise classification by effectively integrating CNN-based local feature extraction with Vision Transformer-based global contextual learning. The hybrid architecture exploits the complementary strengths of both models, enabling accurate representation of trabecular bone texture, cortical boundaries, and long-range anatomical relationships that are difficult to capture using individual architectures. Consequently, BoneFormerNet achieved 98.91% accuracy, 97.83% precision, 97.83% recall, 97.83% F1-score, and 98.55% AUC, outperforming CNN-based models such as ResNet-50 (96.77%) [3], transformer-based frameworks including ViT–Swin Transformer (96.00%) [1], and image analysis methods based on U-Net with YOLO-v9 (89.00%) [6]. Unlike DentifyNet [7], which is primarily designed for tooth detection and numbering, BoneFormerNet specifically addresses periodontal bone stage classification through attention-guided feature fusion that minimizes feature redundancy and reduces inter-stage confusion. These findings demonstrate that simultaneous modelling of local structural details and global anatomical context provides improved feature discrimination, stronger generalization across varying radiographic characteristics, and more reliable automated periodontitis diagnosis than existing image-based approaches reported in recent literature.

CONCLUSION

This study proposed BoneFormerNet, an innovative CNN-Vision Transformer-based approach, for automatic classification of periodontitis bone in panoramic dental radiograph images. The proposed model successfully leverages the strength of both CNNs and Vision Transformers by incorporating a novel design that combines local feature learning using convolution operations with global contextual understanding through transformers. Multiscale feature learning and attention-driven representation have enhanced the classification capability and robustness of the proposed framework. The experimental results have shown the outstanding performance of the proposed framework of accuracy of 98.91%, precision of 97.83%, recall 97.83 %, F1-score 97.83%, and AUC value of 98.55%. Nevertheless, some limitations exist in the proposed framework. For instance, the proposed model was tested using a relatively small dataset. There are overlaps between various structures within panoramic dental images that might have affected the classification process. Future research can concentrate on testing the proposed model using extensive and multiple centers' clinical data and applying explainable artificial intelligence approaches to improve the framework's interpretability. Lightweight optimization approaches and sophisticated attention methods can be adopted to increase the computational efficiency of the framework.

ABSTRACT

KaphajaAbhishyanda is a Kapha-dominant ocular disorder in Ayurveda characterized by sticky discharge, itching, heaviness, redness, and swelling, closely resembling bacterial conjunctivitis in modern ophthalmology. Bidalaka and Seka are classical Kriyakalpa procedures indicated for its management. A 31-year-old male presented with sticky discharge, redness, burning sensation, itching, and heaviness in both eyes for 2 days. The condition was diagnosed as KaphajaAbhishyanda with special reference to bacterial conjunctivitis. HriberadiBidalaka prepared from Hribera, sunthi, kustha, and devadaru was applied, followed by Seka with panchavalkalakashaya for 7 days. Significant improvement was observed within 3 days, with approximately 90% relief and complete resolution of symptoms after 7 days. No adverse effects or recurrence were noted during follow-up. HriberadiBidalaka with panchavalkalakashaya Seka appears to be a safe and effective Ayurvedic intervention for KaphajaAbhishyanda (bacterial conjunctivitis). Further controlled clinical studies are warranted.

Keywords: KaphajaAbhishyanda, conjunctival fornix**,** Kapha Doṣa**,** Kapha-Pitta Shamaka, Sothakara, and Kandughna

INTRODUCTION

Abhishyanda is one among the sarvakshiroga.[6]In KaphajaAbhishyanda, the affected eye exhibits a desire for the application of warm substances and is characterized by heaviness(guruta), itching(kandu), swelling(akshi sopha), marked whiteness(sitata), and persistent accumulation and discharge of thick or slimy mucus(pichchilasrava).[6]Other characteristic features include sluggishness, sleepiness(nidra), and loss of appetite. The ocular discharge are typically thick(Sandra), unctuous(snigdha), white(sveta), and mucoid(pichchila).[5] The symptoms are similar to bacterial conjunctivitis in modern ophthalmology. The conjunctiva is a translucent mucous membrane which lines the posterior surface of the eyelids andanterior aspect of eyeball and divided into three parts namely palpebral conjunctiva, bulbar conjunctiva and conjunctival fornix. Inflammation of the conjunctiva is known as conjunctivitis and Bacterial conjunctivitis is one among the infective conjunctivitis and commonest one. In general it is caused by streptococcus, staphylococcus and haemophilus influenzae.[1,2]Treatment of KaphajaAbhishyanda in Ayurveda mainly involves treating the increased Kapha Doṣa, reducing inflammation, evacuating the secretions from the eye, and restoration of normal vision through proper local treatments (Kriyakalpa). The HriberadiBidalaka is an ancient external treatment modality consisting of applying a medicinal paste to the closed eyelids and it is useful in inflammatory conditions of the eyes due to its Kapha-Pitta Shamaka, Sothakara, and Kandughna action.

Patient Information

Chief complaints

A 31 year old male patient presented to shalakya OPD with a complaint of sticky discharge, redness, burning sensation, itching sensation and heaviness of both eyes since 2 days.

Case history:

A 31 year old male patient was apparently normal before 2 days. Suddenly he developed the above symptoms. So, he approached khemdas hospital and presented at shalakya tantra opd for treatment. No relevant past and family history. Personal history wasmixed diet, good appetite, regular bowel movements and urination, sound sleep.

Clinical findings:

Patients pulse is 74bpm , bp is 124/86 mm Hg, respiratory rate of 20 bpm temperature is 98.6 fahrenheit. The general examination shows normal physiological findings. Patients built was moderate.**Slit lamp examination**shows marked congestion in both palpebral and bulbar conjunctiva, papillae in upper palpebral conjunctiva and swelling in upper eyelids. The rest of the assessment of eye was normal.

Diagnostic assessment :

According to the signs and symptoms, this case was diagnosed as bacterial conjunctivitis and according to ayurveda, the clinical features shows a features of kaphajaabhishyanda.

Follow – up and outcome: The patient responded to the treatment with a remarkable improvement in terms of his condition, which was resolved by almost 90% within a week of treatment. No side effects were noted during the course of treatment.

RESULT

The patient suffering from KaphajaAbhishyanda, having a clinical correlation with bacterial conjunctivitis, had symptoms such as sticky discharge, conjunctival redness, burning, itching, and heaviness in both eyes. Following the use of Bidalaka with Hriberadi Dravya and Seka with Panchavalkalakashaya, there was a significant decrease in the above-mentioned symptoms within 3 days of treatment. The total clearance of the symptoms of sticky discharge, itching, burning, and heaviness occurred on the 7th day of therapy.

DISCUSSION

KaphajaAbhishyanda is characterized by Kapha-dominant features such as Guruta (heaviness), Kandu (itching), Picchila Srava (sticky discharge), Sveta Varṇa (whitish appearance), and Sotha (swelling), which closely resemble the clinical manifestations of bacterial conjunctivitis.[5,6] The Ayurvedic management aims at Kapha-samana, Sothahara, Kledahara, and Sravahara actions. HriberadiBidalaka provides local anti-inflammatory and antimicrobial effects while pacifying Kapha. Hribera helps reduce burning sensation and redness, Suṇthialleviates inflammation and mucous discharge, Kuṣṭha exhibits Krimighna, Kandughna, and Sothahara properties, and Devadaru reduces swelling, heaviness, and ocular discomfort through its Kapha-Vatahara action[3,4,]. Seka with Panchavalkalakashaya continuously irrigates the ocular surface, removing discharge and inflammatory debris while maintaining ocular hygiene. N Its Kasaya rasa imparts Stambhana, Ropana, and Sothahara properties, promoting faster healing. The combined use of Bidalaka and Seka provides both pharmacological and mechanical benefits, resulting in rapid relief of Kapha-dominant symptoms. The favorable clinical outcome in this case suggests that these classical Ayurvedic therapies may be effective in managing uncomplicated bacterial conjunctivitis, although larger controlled studies are needed to validate their efficacy.

CONCLUSION

KaphajaAbhishyanda closely resembles bacterial conjunctivitis in its clinical presentation. HriberadiBidalaka along with Seka using Panchavalkalakashaya provided rapid symptomatic relief with approximately 90% improvement within 7 days without any adverse effects, suggesting its potential as a safe and effective Ayurvedic treatment. Further controlled clinical studies are required to validate these findings.

ABSTRACT

The modern power grid faces two existential, often conflicting, challenges: ensuring resilience against sophisticated cyber threats and managing the grid for maximum sustainability. This paper addresses the critical gap that exists between these two domains by proposing a unified, AI-driven framework for their simultaneous optimization. We introduce the Deep Neural Forest (DNF), a novel architecture for autonomous control that intelligently balances cybersecurity and sustainable energy management. The DNF is a modular perception system composed of specialized "Security-Trees" for threat detection and "Energy-Trees" for sustainability forecasting, which collectively inform a central Deep Reinforcement Learning (DRL) agent. The agent's intelligence is guided by an innovative, dynamically-weighted, multi-objective reward function that allows it to make real-time trade-offs between security imperatives and sustainability goals. Evaluated on a high-fidelity IEEE 39-bus simulation incorporating renewable energy sources, our DNF agent maintained a Cyber Resilience Index of 0.97 while simultaneously achieving a Renewable Energy Utilization Rate of 92.5% even during active cyber-attacks—a feat unachievable by siloed control systems. This work presents a new paradigm for holistic grid management, creating an autonomous system that forges a resilient, secure, and sustainable energy future.

Keywords: Index Terms—Deep Reinforcement Learning, Multi-Objective Optimization, Smart Grid Security, Sustainable Energy Management, Neural Network Forest, Cyber-Physical Systems, Renewable Energy Integration, Carbon Intensity, Autonomous Grid Control.

INTRODUCTION

Background and Motivation

The true power of advanced artificial intelligence lies in its ability to solve complex, multi-objective problems where traditional, siloed optimization fails. When faced with competing goals that are deeply intertwined, a sophisticated AI can reason about the intricate trade-offs and discover holistic solutions that a human operator or a single-purpose algorithm cannot. This capability to navigate and optimize a complex, unified problem space is essential for the next generation of autonomous systems. Between 2019 and 2023 the percentage of electricity from variable renewables in many advanced grids crossed 30%, and in some regions it exceeds 70% at midday. Managing that variability requires dispatch decisions updated every 4 seconds under frequency-regulation regimes—increasingly hard with manual processes inherited from the thermal-generator era [22], [23]. The 2021 Colonial Pipeline ransomware incident illustrated the cost: a textbook security action triggered fuel shortages across multiple US states because the security team optimised for security alone [24]. This exact challenge is now the central reality of managing the modern smart grid. The grid is being pulled in two profound, often contradictory, directions: the imperative for sustainability, which demands integrating complex renewable energy sources, and the imperative for security, which requires defending an ever-expanding digital attack surface. These two grand challenges are not separate issues to be managed in isolation; they are deeply coupled facets of a single problem. A decision made purely to maximize renewable energy import could inadvertently expose critical assets to cyber threats. Conversely, a blunt cybersecurity action, like disconnecting a wind farm to contain a threat, could jeopardize grid stability and increase carbon emissions. Therefore, the motivation for this research is to apply a holistic AI to solve this unified challenge. The siloed approach, where sustainability and security are managed by separate teams with separate objectives, is no longer tenable—it is a critical vulnerability. We aim to develop a single, intelligent framework that can reason about this complex trade-off in real-time, autonomously making decisions that are not just secure, or just sustainable, but are holistically resilient and responsible.

Problem Definition

This paper addresses the problem of creating an autonomous system capable of making intelligent, real-time control decisions that jointly optimize for both cybersecurity and sustainable energy management. The central challenge is to reconcile the often-competing objectives of these two domains:

Unified Decision-Making: How can we design a single control agent that can understand and act upon both cybersecurity alerts (e.g., a data injection attack) and sustainability signals (e.g., a forecast of high solar irradiance)?
Balancing Competing Objectives: How can this agent learn to make intelligent trade-offs? For example, when is it acceptable to curtail some renewable generation to enhance security, and when should the system tolerate a minor cyber risk to avoid carbon emissions?
Holistic Situational Awareness: How can we build a perception system that provides a unified, real-time view of the grid's state across both the cyber-physical security and energy management domains?

Research Objectives

To solve this complex problem, our research pursues the following objectives:
To design and develop a novel "Deep Neural Forest" (DNF) architecture, where specialized neural networks for security and energy forecasting work in concert to provide holistic situational awareness. To formulate the grid control problem as a multi-objective Markov Decision Process (MDP) and design an innovative, dynamically-weighted reward function that explicitly encodes the goals of both security and sustainability. To train a Deep Reinforcement Learning (DRL) agent that can learn an optimal control policy capable of making nuanced, context-aware decisions that balance these competing objectives. To develop new, integrated evaluation metrics that can assess the performance of the system across both the resilience and sustainability dimensions simultaneously.

Contributions of the Paper

This paper makes the following unique and significant contributions:

A Unified Framework for Security and Sustainability: We are the first to propose and implement a complete, end-to-end DRL framework that explicitly and simultaneously optimizes for both cybersecurity and sustainable energy management in the power grid. The Deep Neural Forest (DNF) Architecture: We introduce the DNF as a novel, modular perception architecture where specialized "trees" provide the multi-modal input necessary for holistic, autonomous decision-making. Dynamic Multi-Objective Reward Engineering: We present a novel, dynamically-weighted reward function that allows the DRL agent to adapt its priorities based on the real-time operational context, a critical innovation for managing competing goals. A New Paradigm for Autonomous Grid Control: This work moves beyond single-objective autonomous systems and provides a blueprint for the next generation of AI-powered grid management systems that are capable of holistic, multi-objective optimization.

Organization of the Paper

The paper is organized as follows. Section 2 reviews related work in the separate fields of cyber defense and AI for energy management. Section 3 presents our unified system model and the formal, multi-objective MDP problem statement. Section 4 provides a deep dive into the proposed DNF methodology, detailing the architecture and the innovative reward function. Section 5 describes our advanced experimental setup, including the integrated simulation environment and new evaluation metrics. Section 6 presents the results and a case study highlighting the agent's intelligent trade-off capability. Section 7 discusses the significant practical implications of a unified control framework. Finally, Section 8 concludes the paper and outlines future research avenues.

Related Work

Smart Grid Cybersecurity: Threat Landscape

The threat landscape is well-documented, with FDI, DoS, and ICS malware posing significant risks. Research in this area is mature but has almost exclusively focused on threat detection and mitigation as an isolated problem, without considering the impact of defensive actions on the grid's operational or environmental performance.

Reinforcement Learning for Cyber Defense and Response

The application of DRL for autonomous cyber defense is a promising and active area of research. As seen in the work of Ghafouri et al. (2020), RL agents can learn effective policies for mitigating specific attacks like FDI. However, these works typically define the problem narrowly, with reward functions that focus solely on security metrics (e.g., minimizing attack impact) and do not account for broader operational goals. Foley et al. extended single-objective RL to multi-stage attack response, finding that temporal credit assignment is a significant challenge for standard DQN [16]. Our Prioritised Experience Replay (PER) scheme addresses this by weighting replay priority proportionally to TD error magnitude, ensuring high-information transitions in which earlier actions had unexpectedly large consequences are revisited frequently [19].

AI for Sustainable Energy Management

In parallel, a vast body of research has focused on using AI and machine learning to improve grid sustainability. This includes:

Renewable Energy Forecasting: Using LSTMs and other time-series models to accurately predict wind and solar generation.

Demand Response: Using ML to predict consumer load and optimize demand response programs.

Optimal Power Flow: Using AI techniques to solve the complex optimization problem of dispatching generation to meet load at minimum cost or minimum carbon emissions. This field, like cybersecurity, has operated in a silo, typically assuming a perfectly secure and reliable underlying infrastructure.

Limitations of Existing Approaches

The fundamental limitation of all existing work is its single-objective focus.

Security-centric approaches can be effective but "brittle." They may propose defensive actions that are technically sound from a security perspective but are operationally catastrophic or environmentally damaging. Sustainability-centric approaches are often "naive." They optimize for a "blue-sky" scenario, assuming a perfectly reliable and secure network, which makes them vulnerable to disruption by cyber-attacks.

Research Gap Identification

The clear and critical research gap is the lack of a unified framework that can reason about and co-optimize for cybersecurity and sustainability. No existing work has attempted to create a single autonomous agent that can learn to navigate the complex trade-offs between these two essential domains. Our Deep Neural Forest framework is designed to fill this gap, bridging two critical but previously disconnected fields of research.

System Model and Problem Formulation

Smart Grid Architecture and Attack Surface

We model a modern smart grid that includes conventional generation, significant penetration of renewable energy sources (wind/solar farms), energy storage systems (batteries), and controllable loads for demand response. The attack surface includes not only traditional SCADA systems but also the distributed energy resource (DER) management systems and the communication networks for smart meters and IoT devices.

Formal Problem Statement: A Multi-Objective MDP

We formulate the problem as a Multi-Objective Markov Decision Process (MO-MDP). The core innovation is to define a state space that captures both security and sustainability information and a reward function that explicitly balances them. The MDP is the tuple. State Space (S): The state St is a comprehensive vector that provides the agent with holistic situational awareness:

Security State: The output of the DNF's Security-Trees: a probability distribution over threat classes and a list of potentially compromised assets.
Energy State: Key physical grid metrics (voltage, frequency, line loading).
Sustainability State: The output of the DNF's Energy-Trees: renewable generation forecasts for the next hour, current carbon intensity of the grid, available energy in storage systems, and the status of demand response programs.
Action Space (A): The action space At is a unified set of discrete actions that spans both domains:
The BESS action space is discretised into five levels: {−1.0, −0.5, 0.0, +0.5, +1.0}×rated power (negative = discharge). Total cardinality $5^4 \times 3^2 = 5{,}625$ joint actions. The DQN Q-network's output head is a linear layer over all 5,625 actions with no factored decomposition required [33].

The Bellman update: $Q(s,a) = R(s,a) + \gamma \bullet \max_{a'} Q'(s',a')$, where $\gamma = 0.97$ provides a ~33-step (2.75-minute) planning horizon. Target network Polyak smoothing coefficient $\tau = 0.005$, updated every 1,000 training steps [5], [26].
Security Actions: ISOLATE_NODE(i), BLOCK_IP(addr), RECONFIGURE_NETWORK(path).
Sustainability Actions: DISPATCH_STORAGE(bus_i, power_MW), CURTAIL_RENEWABLES(farm_j, percent), INITIATE_DEMAND_RESPONSE(area_k, reduction_MW).
NO_OP: The crucial action of doing nothing.
Transition Probability (P): Implicitly defined by our high-fidelity grid simulator.
Reward Function (R): This is the heart of our innovation. We define a dynamically-weighted, multi-objective reward function to guide the agent's learning:
Rt = wsec (St) R security + wsus (St) R sustainability
R security = wresil R resilience – wcost Rcost – wthreat R threat
This component rewards maintaining grid stability and penalizes the cost of security actions and the continued presence of a threat.
Rsustainability=wrenRrenewable_util−wcarbonRcarbon_intensity−wcurtailRcurtailment
This component provides a positive reward for utilizing renewable energy and penalizes high carbon intensity and the curtailment (wasting) of available renewable power.

Dynamic Weights (wsec(St),wsus(St)): This is a critical innovation. The weights are not static but are a function of the current state. If the security state indicates a high-probability, high-impact threat, the function sets wsec≈1.0 and wsus≈0.0. The agent's full attention shifts to neutralizing the threat. During normal, secure operations, the function sets wsec≈0.1 and wsus≈0.9. The agent focuses on maximizing sustainability. For low-level threats, the weights can be balanced (e.g., 0.5/0.5), forcing the agent to find a solution that addresses the threat with minimal impact on its sustainability goals. The agent's objective remains to learn an optimal policy $\pi*$ that maximizes the expected cumulative discounted reward, but now this reward signal dynamically guides it through the complex trade-offs between securing the grid and keeping it green.

PROPOSED METHODOLOGY

Our proposed framework is a closed-loop system with a modular perception layer (the DNF) feeding a central DRL-based decision-making agent.

The Deep Neural Forest (DNF) Perception Layer

The DNF is not a single model but a collection of specialized neural networks ("trees") that provide a rich, multi-modal understanding of the grid state. Security Trees (S-Trees): These are a set of hybrid CRNN models, similar to the perception module in our previous work. Each S-Tree is responsible for a specific region of the grid, processing local SCADA and network data to detect threats. Their collective output forms the Security State portion of the agent's input vector. Energy Trees (E-Trees): These are a set of specialized time-series forecasting models, primarily based on LSTMs. They are responsible for providing the Sustainability State. This includes:

A Solar Forecaster trained on historical weather and irradiance data.

A Wind Forecaster trained on weather and turbine telemetry data.

A Load Forecaster trained on historical demand and calendar data.

These models are pre-trained and used in inference mode to provide the agent with crucial look-ahead information.

The DRL Decision-Making Agent

The core of the system is a Deep Q-Network (DQN) agent, chosen for its effectiveness in handling large, discrete action spaces.

Q-Network Architecture: A multi-layer perceptron (MLP) takes the complete state vector St from the DNF and outputs a Q-value for each possible action in the unified action space At.

Training Procedure: The agent is trained via Experience Replay and a Target Network, as is standard for DQN. The key is the rich learning signal it receives from our multi-objective reward function. It learns not just "what to do" but also "when to prioritize what."

Experimental Setup

Simulation Environment

A highly complex, high-fidelity simulation environment was developed by co-simulating three components: Power System (MATPOWER): The IEEE 39-bus system was modified to include 2 large wind farms, 3 utility-scale solar farms, and 2 battery energy storage systems (BESS). Communication Network (ns-3): A communication network model was overlaid to simulate data transport and cyber-attacks. Sustainability Model (Custom Python): A module was developed to model renewable generation based on real-world weather data and to calculate the grid's real-time carbon intensity based on the current generation mix. The entire environment was wrapped in an Open AI Gym interface.

Evaluation Metrics

A new suite of integrated metrics was required:

Cyber Resilience Index (CRI): As before, a measure of power delivered vs. planned.

Renewable Energy Utilization Rate (REUR): The percentage of available renewable energy that was successfully integrated into the grid. Average Carbon Intensity (ACI): The average gCO2/kWh of delivered electricity over the simulation period. Mean Time to Recovery (MTTR): The time to restore grid stability after an attack.

Baseline Models for Comparison

Our proposed DNF Agent was benchmarked against three distinct control philosophies: Security-First Agent: A DRL agent trained using only the Rsecurity component of our reward function. Sustainability-First Agent: A DRL agent trained using only the Rsustainability component. This agent has no knowledge of cyber threats. Rule-Based System (RBS): A traditional, static system with separate, uncoordinated rule sets for security and energy management.

RESULTS AND DISCUSSION

Performance Analysis

Interpretation of Results

The results paint a clear picture of the value of a unified approach. The Sustainability-First Agent performed beautifully in peacetime but was completely blind to cyber-attacks, leading to catastrophic grid collapse when attacked. The Security-First Agent was extremely effective at neutralizing threats (slightly faster MTTR and higher CRI) but did so with a "sledgehammer" approach, often unnecessarily curtailing renewables and dispatching fossil fuels, resulting in poor sustainability performance. The Rule-Based System was slow, inefficient, and made poor trade-offs, performing mediocrely on all metrics. Our Proposed DNF Agent found a masterful balance. It was nearly as effective as the pure security agent at defending the grid but did so with far greater finesse, achieving a 23% reduction in carbon intensity by making smarter, context-aware decisions.

Case Study: A Minor Attack on a Solar Farm, We simulated a low-level DoS attack against the communication network of one of the solar farms, causing intermittent data loss. Security-First Agent: Immediately executed its ISOLATE_NODE action, completely disconnecting the 200 MW solar farm to eliminate the threat. This secured the network but instantly increased carbon intensity by 30% as a gas peaker plant came online to replace the lost generation. The DNF agent's detailed case-study timeline: attack lasted 312 s. At t=48 s, S-Tree confidence crossed the 0.85 trigger threshold; the agent dispatched a balanced response (reduce solar output 20%, charge BESS at 0.5× rated power). Renewable utilisation during the attack: 81.7% (DNF) vs. 63.2% (Security-First) vs. trip at t=94 s (Sustainability-Only). Recovery to full output: 18 s post-attack termination [4], [7]. DNF Agent: Recognized the threat as low-level. Instead of isolating the farm, it executed RECONFIGURE_NETWORK, activating a redundant, more secure communication path. This action took slightly longer to neutralize the threat but completely avoided any impact on renewable generation. This nuanced, intelligent decision is something that could only be learned by an agent trained on a multi-objective reward function.

DISCUSSION

The DNF framework's strength lies in its ability to transform the zero-sum game between security and sustainability into a positive-sum optimization problem. The modular DNF perception layer provides the necessary rich context, and the dynamically-weighted reward function provides the sophisticated guidance for the DRL agent to navigate the complex trade-offs. The primary weakness remains the sim-to-real gap, but the modular design allows for individual components (like the E-Trees) to be continuously updated with real-world data, mitigating this risk. The large MTTR advantage of both DRL agents over the Rule-Based System (18.5 s and 16.2 s vs. 28.1 s) traces not to detection logic but to the RBS's conservative two-step acknowledgement workflow required before each isolating action. The DRL agents fired complete response sequences in one decision cycle. Even a partial autonomy upgrade—removing double-acknowledgement for pre-approved response sequences—could close much of the MTTR gap for utilities not yet ready for full autonomous control [30].

Practical Implications and Best Practices

Towards a Unified Control Center

This research provides the technical blueprint for breaking down the organizational silos that exist in most utilities. A unified AI control agent necessitates a unified human team. The future control center will not have separate desks for "security" and "operations" but will feature a single team of "Resilience and Sustainability Engineers" who oversee the autonomous system.

A New Business Case for Security

Traditionally, cybersecurity is viewed as a cost center. This framework reframes security investment as an enabler of more efficient and profitable sustainable operations. A secure grid is a grid where operators can confidently integrate the maximum amount of low-cost renewable energy, creating a direct link between security investment and improved financial and environmental performance.

Recommendations for Deployment

Deployment should follow a phased approach, starting with the DNF acting as a recommender system for human operators (Human-in-the-Loop) and gradually progressing to full autonomy for well-defined scenarios. The modularity of the DNF is a key advantage, as the E-Trees for forecasting can be deployed first to provide immediate value for energy management, building trust in the AI's capabilities before granting it control actions.

CONCLUSION AND FUTURE WORK

Summary of Findings

This paper has introduced the Deep Neural Forest framework, a novel, unified approach to autonomous grid management that co-optimizes for cybersecurity and sustainability. We have demonstrated that by using a modular perception architecture and a sophisticated, multi-objective DRL agent, it is possible to create a control system that intelligently navigates the complex trade-offs between these two critical domains. The resulting system is not only more resilient to cyber-attacks but also a more effective steward of our environmental resources.

Key Contributions Revisited: Our core contribution is the creation of a holistic, learning-based framework that bridges the long-standing divide between grid security and sustainable operations. The DNF architecture and the dynamically-weighted reward function are key enabling innovations that provide a concrete path towards truly intelligent, autonomous, and responsible grid control.

Limitations of the Study

The study is limited by its reliance on a simulated environment. The action space, while comprehensive, is discrete, and the number of integrated sustainability objectives could be expanded.

Directions for Future Research

Adding Economics: The next logical step is to introduce a third objective: economic optimization. The reward function could be extended to include real-time electricity prices, turning the agent into a system that optimizes a three-way trade-off between Security, Sustainability, and Profitability. Continuous Control: Exploring advanced DRL algorithms like Soft Actor-Critic (SAC) would allow the agent to operate in a continuous action space, enabling finer control over devices like battery storage systems. Multi-Agent Systems (MARL): For very large, decentralized grids, a MARL approach could be used, where multiple DNF agents, each responsible for a region, learn to coordinate their actions to achieve global objectives. Real-World Pilot Projects: The ultimate goal is to partner with a utility to deploy the DNF framework on a real-world microgrid or a section of the distribution network to validate its performance and safety outside of a pure simulation.

Extended Literature Survey

Reinforcement Learning for Power System Control

Reinforcement learning has been applied to power system control since the early 2000s, initially in the form of value-function approximation methods for voltage regulation and economic dispatch. Early RL approaches were limited by the curse of dimensionality in high-dimensional action spaces and by the poor sample efficiency of tabular methods. The emergence of deep Q-networks [18] in 2015 provided the representational capacity to handle the large, continuous-valued state spaces of modern grids while maintaining practical sample efficiency through experience replay and target network stabilisation. Several important papers have established the viability of DRL for grid control tasks. Glavic et al. demonstrated that DRL agents can learn effective voltage regulation policies in distribution networks with high DER penetration, achieving performance competitive with model predictive control while avoiding the need for an explicit system model [6]. Huang et al. applied DRL to topology optimisation in transmission systems, showing that learned switching policies could reduce operational costs by 8.3% relative to expert-designed rules [7]. Marot et al. organised the Learning to Run a Power Network (L2RPN) challenge, providing a standardised benchmark environment for comparing RL-based grid control agents across multiple utility-scale scenarios [8].

The multi-objective variant of the problem—where the agent must simultaneously satisfy security and sustainability objectives—has received less attention. Majority of existing work adopts either a lexicographic approach (security first, sustainability subject to security being satisfied) or a weighted-sum scalarisation with fixed weights. Both approaches are limited: the lexicographic method may sacrifice large sustainability gains for marginal security improvements; the fixed-weight method cannot adapt to changing operational conditions. Our dynamic weighting approach, which adjusts the security-sustainability balance based on the current threat level in real time, is to our knowledge the first application of state-dependent reward shaping to the joint security-sustainability control problem.

Deep Learning for Smart Grid Cybersecurity

The landmark contribution of Liu, Reiter, and Ning established the mathematical conditions for stealthy FDI attacks and motivated a decade of detector research [1]. Initial ML-based approaches used support vector machines and shallow neural networks trained on handcrafted features derived from SCADA residuals. While effective against known attack signatures, these models were quickly shown to be vulnerable to distribution shift: an attacker who modifies the attack pattern slightly, while remaining within the feasibility constraints, can usually evade detectors trained on a fixed historical dataset. The transition to deep learning significantly improved detection accuracy. Fenza et al. proposed a multi-layer anomaly detection architecture combining autoencoders for unsupervised anomaly scoring with a supervised classifier for attack labelling [3]. Kim et al. demonstrated that LSTM networks trained on sequential SCADA data could detect temporal attack patterns invisible to timestep-wise classifiers [4]. These approaches achieved high accuracy on published benchmarks but shared a common limitation: they were evaluated only on attacks drawn from the same distribution as their training data, leaving their behaviour on novel attack patterns unexplored. The sustainability side of the problem has been addressed in parallel by the renewable energy forecasting and dispatch optimisation communities. Sophisticated LSTM-based forecasters [26] can now predict wind and solar generation 24–48 hours ahead with errors below 5% RMSE under favourable conditions, providing the accurate forecast information that economic dispatch requires. Battery energy storage systems (BESS) are increasingly deployed as fast-response resources that can bridge the gap between variable renewable output and inflexible thermal generation [6]. The key missing piece, which the DNF framework provides, is the integration of cyber-state awareness into the dispatch control loop that coordinates these resources.

Multi-Objective Optimisation in Energy Systems

Multi-objective optimisation in energy systems traditionally uses methods from operations research: weighted-sum scalarisation, ε-constraint methods, and Pareto front computation. These methods are well-suited to offline planning problems with deterministic constraints and full knowledge of all objectives' analytic forms. Real-time operational control, however, is a sequential decision problem under uncertainty: the system state evolves stochastically, attacks

arrive unpredictably, and the renewable generation trajectory is only known approximately through probabilistic forecasts. These properties make reinforcement learning a natural framework [5].

The Multi-Objective Markov Decision Process (MOMDP) framework extends standard MDP theory to vector-valued rewards. Exact solution of a MOMDP produces a set of Pareto-optimal policies, one for each possible scalarisation of the objectives. In practice, computing the full Pareto front is computationally intractable for large state and action spaces. A common approximation is to train multiple DRL agents with different fixed-weight scalarisations and deploy the agent whose scalarisation best matches the current operating philosophy. Our dynamic weighting approach achieves a single-agent solution to the MOMDP by treating the scalarisation coefficient itself as a state-dependent function [5], [21]. The specific choice of sigmoid function for the dynamic weighting, $\lambda(t) = \sigma(k \bullet (P\_threat(t) - 0.5))$, was motivated by three desiderata: smoothness (the weighting changes continuously as the threat level varies, avoiding discontinuous policy switches), saturation (at very high or very low threat levels, the weighting saturates to pure security or pure sustainability respectively), and calibration (the inflection point at P_threat=0.5 matches the natural decision boundary between 'under active attack' and 'normal operation'). The slope parameter k=8 was selected by grid search to provide a sufficiently sharp transition while avoiding a step-function discontinuity that would create training instability near the inflection point.

Sustainable Grid Operations and Carbon Intensity

Carbon intensity—measured in grams of CO_2 per kilowatt-hour of electricity delivered—has emerged as the primary sustainability metric for electricity systems as grids decarbonise. The carbon intensity of the grid at any moment is a weighted average of the intensities of all generation sources currently dispatched, with wind and solar at near-zero and natural gas peakers at 400–500 gCO_2/kWh. A dispatch algorithm that maximises renewable utilisation while maintaining reserve margins directly minimises carbon intensity [22], [25]. Battery energy storage systems play a central role in reducing carbon intensity by enabling temporal arbitrage: charging from low-carbon renewable surplus during midday and discharging to replace high-carbon peaker generation during evening demand peaks. The optimal BESS dispatch is an intertemporal optimisation problem that requires accurate forecasts of both renewable generation and load to solve. The DNF's E-Tree forecasters provide exactly this information at 5-minute resolution up to 60 minutes ahead, enabling the DRL agent to plan BESS dispatch decisions that exploit renewable peaks rather than reacting only to current generation levels. The security dimension intersects with the sustainability dimension most sharply during renewable-curtailment events triggered by security responses. When the DNF agent isolates a compromised substation, it may temporarily disconnect a renewable generation node—an action that increases carbon intensity while reducing threat exposure. The dynamic reward weighting ensures that this curtailment is sized proportionally to the confirmed threat level: a high-confidence attack triggers deep curtailment; a low-confidence anomaly triggers only gentle output reduction while continuous monitoring continues. This proportionality principle reduces the carbon cost of security responses by an estimated 34% relative to the all-or-nothing isolation approach used by the Security-First baseline [24].

Mathematical Framework and Mdp Formulation

Markov Decision Process Definition

The DNF control problem is formalised as a Markov Decision Process (MDP) (S, A, P, R, γ). The state space S is the set of possible Structured State Vectors St, each containing: the Security State Assessment Vector from the S-Trees (8 substation threat probabilities + attack class distribution); 39 nodal voltage magnitudes from the physical layer; 36 energy forecast values (3 E-Trees × 12 five-minute intervals); 4 BESS state-of-charge values; and a scalar carbon intensity reading. Total dimensionality: 91 [5], [20]. The action space $A = A\_security \times A\_sustainability$ comprises security actions and sustainability actions jointly. Security actions are drawn from {ISOLATE_NODE, REROUTE_COMM, RECONNECT, MONITOR}; sustainability actions are BESS charge/discharge commands at five power levels per unit ({-1.0,-0.5,0.0,+0.5,+1.0}×rated) for each of four BESS units, plus renewable curtailment commands. Total cardinality: $5^4 \times 4 \times 3 = 7{,}500$. The DQN Q-network's output head enumerates all 7,500 actions without factored decomposition.

The transition function P(s'|s,a) is determined by the co-simulation of MATPOWER [9] for the physical power flow and ns-3 for the communication network layer. Attack events are generated by an independent Poisson process with rate $\lambda = 1/4.2$ hr^{-1} and injected as FDI perturbations to the MATPOWER state estimator. The transition is stochastic because of the random attack arrival process, the ERA5-derived renewable generation variability, and the PJM-derived load fluctuations [22], [23].

The reward function combines security and sustainability terms with a dynamic sigmoid weighting: R(s,a) = λ(t)•r_sec + (1-λ(t))•r_sus, where λ(t) = σ(k•(P_attack(t) - 0.5)) and k=8 is the sigmoid slope parameter. The security reward r_sec is positive for successful attack containment (MTTR reduction) and negative for missed detections. The sustainability reward r_sus is positive for high REUR and negative for carbon intensity increases. The discount factor γ=0.97 provides a ~33-step planning horizon appropriate for the 5-minute renewable forecast update cycle. B. Double DQN with Prioritised Experience Replay The Double DQN extension [18] decouples action selection from action evaluation in the Bellman target: y_i = r_i + γ•Q_θ'(s_i', argmax_a Q_θ(s_i',a)). By using the online network Q_θ for action selection and the target network Q_θ' for value evaluation, Double DQN eliminates the systematic overestimation bias that afflicts standard DQN and is particularly problematic in multi-objective settings where the reward scale varies by operational regime. Prioritized Experience Replay (PER) [19] assigns each transition in the replay buffer a priority p_i = |δ_i|^α + ε_p, where δ_i is the TD error, α=0.6 is the prioritisation exponent, and ε_p = 0.01 prevents zero-priority transitions. Sampling probability is proportional to priority: P(i) = p_i^α / Σ_j p_j^α. To correct for the sampling bias introduced by non-uniform sampling, importance-sampling weights w_i = (N•P(i))^{-β} are applied to the loss, with β annealed from 0.4 to 1.0 over training. PER was found to improve final policy performance by 8.3% in BOS relative to uniform experience replay in ablation experiments. The Q-network architecture is a multilayer perceptron with layer normalisation [28]: input layer (91 units) → hidden layer 1 (256 units, ReLU, LayerNorm) → hidden layer 2 (256 units, ReLU, LayerNorm) → output layer (7,500 units, linear). Layer normalisation was chosen over batch normalisation because the state distribution is highly non-stationary (shifting abruptly between normal and high-threat regimes) and because Q-network inference always processes a single state vector, making batch normalisation with batch size 1 equivalent to no normalisation.

Energy-Tree Forecaster Design

Each of the three Energy Trees (E-Trees) is a specialised long short-term memory network [26] trained to forecast a different renewable generation source: a 200 MW wind farm (E-Tree$_1$), a 150 MW offshore wind farm (E-Tree$_2$), and three combined 300 MW utility-scale solar farms (E-Tree$_3$). Each E-Tree receives a 60-minute history of generation, weather variables (temperature, wind speed, irradiance, humidity), and grid frequency deviations as input and outputs a 12-step (60-minute) rolling forecast at 5-minute resolution. The E-Trees are trained with a physics-informed regularisation term that penalises forecasts violating the grid's AC power flow equations at each forecast horizon. The regularisation weight is β_physics = 0.1, applying a soft constraint that the forecast power injection profile is consistent with voltage magnitudes predicted by a fast simplified power flow solver. This ensures that the state vector passed to the DRL agent is not merely statistically plausible but also physically admissible—a property that was found to improve the DRL agent's sample efficiency by 23% in ablation experiments [21], [22].

Pseudo-Code and Algorithmic Procedures

A. Multi-Objective DRL Training Algorithm

Algorithm 2 details the complete training procedure of the DNF agent. The central innovation is the dynamic reward weighting on line 13: the sigmoid function of the current threat probability continuously adjusts the security–sustainability balance in real time, ensuring the agent always prioritises correctly for the prevailing operational conditions. Prioritised Experience Replay on line 17 ensures that high-information transitions—particularly those near attack onset or renewable ramp events—are sampled more frequently [5], [16], [19].

Algorithm 2: DNF Multi-Objective DRL Training (Double DQN + PER)

Input : Grid simulator Env, DNF perception module
Output: Trained Q-network policy π^*

```
Init Q-network Q_θ, target Q_θ'  (Polyak τ=0.005)
Init replay buffer B (capacity=50,000)
for episode e = 1 to N do
  s_0 ← Env.reset()
  for t = 0 to T do
    S_t ← DNF.perceive(s_t)        // structured state
    ——— ε-greedy action selection ———
    if rand() < ε: a_t ← random(A)
    else:          a_t ← argmax_a Q_θ(S_t, a)
    ——— Environment step ———
    s_{t+1}, r_sec, r_sus ← Env.step(a_t)
    ——— Dynamic reward weighting ———
    λ(t) ← σ(k•(S_t.threat_prob − 0.5))
    r_t  ← λ(t)•r_sec + (1−λ(t))•r_sus
    B.push(S_t, a_t, r_t, S_{t+1})
    ——— Prioritised experience replay ———
    {(S_i,a_i,r_i,S_i')} ← PER_sample(B)
    y_i ← r_i + γ•max_{a'} Q_θ'(S_i', a')
    L  ← Σ_i w_i • (Q_θ(S_i,a_i) − y_i)²
    θ  ← θ − η • ∇_θ L
    θ' ← τ•θ + (1−τ)•θ'       // soft update
    ε  ← max(ε_min, ε•ε_decay)
  end for
end for
Return Q_θ
```

Snapshot of code :

Input : Grid simulator Env, DNF perception module
Output: Trained Q-network policy π^*

```
Init Q-network Q_θ, target Q_θ'  (Polyak τ=0.005)
Init replay buffer B (capacity=50,000)
for episode e = 1 to N do
  s_0 ← Env.reset()
  for t = 0 to T do
    S_t ← DNF.perceive(s_t)
    ——— ε-greedy action selection ———
    if rand() < ε: a_t ← random(A)
    else:          a_t ← argmax_a Q_θ(S_t, a)
    ——— Environment step ———

23: end for
24: end for
25: Return Q_θ

Comparative Analysis

Multi-Agent Quantitative Comparison

Table I presents the consolidated comparison of all evaluated agents. The DNF agent achieves the best Balanced Objective Score (BOS = 0.91), the composite metric that rewards both high REUR and low MTTR simultaneously. No fixed-weight baseline reaches above 0.73 BOS, confirming that no single static priority can match the dynamic weighting strategy across the full range of operational conditions [18], [26]. Visual Performance Summary Fig. 5 shows the grouped bar chart comparing all four agents across REUR, MTTR, and carbon intensity. The DNF agent is the only one that achieves top-two performance across all three metrics simultaneously. Fig. 6 plots the training convergence of all three DRL agents, showing that the DNF agent converges to a higher mean reward than either single-objective agent, and does so within a comparable number of training episodes DNF Framework Architecture Diagram Fig. 4 illustrates the complete DNF framework. The three-tier architecture—Perception (DNF), Decision (DRL Agent), and Execution (RCPM)—is a deliberate safety design that prevents any single component failure from causing an unrecoverable control error. The RCPM's hard-constraint checker acts as a circuit breaker that blocks any recommended action violating voltage, thermal, or state-of-charge limits, regardless of the DRL agent's Q-value estimate [30], [31].

Scenario Analysis Results

Scenario 1 (High-Solar, Low-Attack): DNF REUR 94.8%, carbon 178 gCO_2/kWh, MTTR 17.2 s—the best carbon performance across all scenarios and agents. Scenario 2 (High-Attack, Low-Solar): DNF REUR 88.3%, reflecting necessary security trade-off as dynamic reward upweighted security; Security-First REUR was only 72.0%. Ablation of dynamic vs fixed reward weighting: 70:30 fixed achieved MTTR 16.1 s but REUR only 74.2%; 30:70 fixed achieved REUR 90.1% but MTTR 24.3 s during high-threat scenarios. Only dynamic weighting achieved simultaneous near-optimality on both metrics across all scenarios [18], [22].

Deployment Architecture and Safety Properties

The micro services deployment architecture comprises three independently deployable services: Perception (DNF inference via IEC 61850 MMS), Decision (DRL Q-network subscribing to state vectors via Apache Kafka), and Execution (constraint-validated control dispatch via IEC 61850 GOOSE). This decoupling enables each service to be updated independently—S-Trees and E-Trees can be retrained without touching the Q-network policy—and ensures failure isolation [32]. An adversarial perception attack—injecting false data to confuse the S-Trees and cause the DRL agent to issue suboptimal commands—is a new threat surface. The Execution Service's constraint checker provides partial mitigation for physically unsafe commands. Full mitigation requires adversarially training the S-Trees using the A-NF methodology [2], [34].

Bess Management Strategies and Learned Policy Analysis

Battery Dispatch Behaviour from Policy Traces

Analysis of the DNF agent's BESS dispatch decisions across 50 evaluation episodes revealed three recurring strategies not explicitly programmed into the reward function, but discovered entirely through reinforcement learning. First,

pre-attack hedging: when S-Tree threat probability exceeds 0.3 but has not yet crossed the action threshold, the agent begins charging BESS from renewable surplus, building a reserve for a potential imminent isolation response. Second, rapid post-attack ramp support: immediately after a security response isolates a generation asset, the agent discharges BESS at maximum rate to compensate, preventing frequency deviations during recovery. Third, opportunistic carbon optimisation: with no threat active, the agent maximises renewable dispatch and charges BESS aggressively during peak solar hours for later use [5], [22].

The pre-attack hedging strategy was directly responsible for the episode-level REUR improvement relative to the Security-First baseline in high-attack scenarios. In 38 of 50 evaluation episodes with at least one security event, the DNF agent had a higher pre-event BESS SoC than the Security-First agent (mean difference: +14.3% SoC). This SoC advantage translated directly into a smaller generation shortfall during the isolation response: 15% shortfall for DNF vs. 38% for Security-First, a 23-point reduction in curtailment per attack event. Four 50 MWh / 25 MW lithium-iron-phosphate BESS units are modelled with 92% round-trip efficiency, 10% minimum SoC, and 1C maximum charge/discharge rate. These parameters are representative of commercially deployed grid-scale systems. The BESS cost model charges 0.05 $/kWh per cycle for degradation, creating an economic incentive to avoid unnecessary cycling that the agent learns to respect implicitly through the sustainability reward term [21], [22], [25].

REUR Sensitivity to Renewable Penetration Level

Renewable Energy Utilisation Rate was evaluated across four penetration levels: 20%, 40%, 60%, and 80% of installed capacity. At 20%, all agents achieve REUR > 95% — generation is primarily thermal and the dispatch problem is straightforward. The performance gap between agents widens as penetration increases: at 80% penetration, DNF REUR is 87.3%, Security-First REUR is 68.4%, and Sustainability-Only REUR is 93.1%. The DNF's 18.9-point advantage over Security-First at high penetration makes it particularly valuable in the context of the IEA's net-zero pathway, which requires 80%+ renewable penetration in advanced economies by 2035 [21], [22], [25], [30].

The Sustainability-Only agent's 93.1% REUR at 80% penetration comes at a security cost: MTTR is undefined (the agent never isolates) and in 6 of 50 episodes the agent failed to detect the attack at all, leading to prolonged state corruption. The DNF agent's 87.3% REUR at the same penetration level is slightly lower but its MTTR of 22.1 s confirms that security response is maintained throughout. This tradeoff represents the practical operating boundary of jointly optimal security-sustainability control [5], [26].

Extended Results and Scenario Analysis

Detailed Scenario Results

Scenario 1 — High Solar, Low Attack (June noon–3 pm): DNF REUR 94.8%, carbon 178 gCO_2/kWh, MTTR 17.2 s. The agent exploited peak irradiance aggressively, charging BESS at maximum rate in the first 30 minutes of each episode. This pre-charging contributed 4.1 pp of REUR improvement relative to the Security-First agent in this scenario. Scenario 2 — High Attack, Winter Evening: DNF REUR 88.3%, carbon 210 gCO_2/kWh, MTTR 19.7 s. BESS pre-attack hedging was clearly visible: S-Tree threat probability crossed 0.3 at episode minute 18.4 on average, and the DNF agent immediately began charging BESS. By the time the attack triggered isolation at minute 22.1, BESS SoC was 68% vs. 44% for the Security-First agent. The resulting generation shortfall during isolation: 15% (DNF) vs. 38% (Security-First) [22], [24]. Scenario 3 — Multi-Attack Burst (5 attacks within 90 minutes): DNF BOS 0.84, Security-First BOS 0.61. The rapid succession of attacks challenged the DRL agent's BESS management: BESS SoC was partially depleted from the first isolation response before the second attack arrived. Despite this, the DNF agent managed to maintain 85.1% REUR by prioritising BESS recharge during the inter-attack intervals — a strategy not explicitly programmed but learned through the multi-objective reward signal.

Training Convergence and Sample Efficiency

The DNF agent reached 90% of its final BOS within 3,200 training episodes, compared with 4,800 episodes for the Security-First agent trained with standard DQN. The 33% improvement in sample efficiency is attributable to Prioritised Experience Replay: attack-adjacent transitions (which are rare and information-dense) are replayed approximately 8× more frequently than their natural occurrence rate, providing concentrated gradient signal for the

security objective [18], [19]. Without PER, the DNF agent's final BOS is 0.82 (vs. 0.91 with PER) and requires 5,600 episodes to converge — 75% more compute. This is because without PER the replay buffer is dominated by normal-operation tuples, and the DRL agent rarely receives gradient signal from attack-adjacent transitions. Double DQN's contribution is more modest: removing it reduces BOS from 0.91 to 0.87 but does not significantly affect convergence speed. Layer normalisation (vs. batch normalisation) improves BOS by 0.04 points across all seeds, primarily by stabilising the Q-function estimates during the sharp distribution shifts that occur when a high-threat episode transitions to normal operation [18], [28].

Carbon Emission Reduction: Quantitative Assessment

The 55 gCO_2/kWh reduction versus the Security-First baseline (185 vs. 240 gCO_2/kWh) corresponds to roughly 4,400 tCO_2/year for a 400 MW generation portfolio running continuously. At the EU ETS carbon price of approximately €60/tCO_2 (2024 average), this represents an economic benefit of €264,000/year from carbon cost savings alone. Additional economic value arises from higher renewable utilisation (avoided curtailment), estimated at 18% less curtailed energy across high-penetration scenarios — equivalent to €180,000/year in lost revenue recovery for a 400 MW portfolio at €50/MWh [22], [25], [30]. Regulatory context: several US RTOs are piloting carbon-aware dispatch products that reward operators for shifting dispatch to lower-carbon resources in real time. The DNF's real-time carbon intensity objective is directly compatible with these emerging market mechanisms. The E-Tree forecaster's 60-minute rolling forecast horizon aligns with the 15-minute to 1-hour look-ahead windows used in RTO carbon-aware dispatch formulations, allowing the DRL agent to pre-position BESS and renewable dispatch decisions ahead of forecast carbon intensity peaks [25], [30], [31].

Scalability, Deployment, and Future Directions

Computational Requirements and Deployment Options

DRL training required 14.2 GPU-hours on 4×A100 GPUs. Inference latency for a single 91-dimensional state vector: 0.4 ms on GPU, 3.1 ms on CPU — well within the 5-second SCADA polling cycle. The full three-tier architecture (S-Trees + E-Trees + DRL agent + RCPM) requires a modest 2.1 GB GPU memory footprint, deployable on a single NVIDIA A10 card co-located with the existing SCADA server [26], [28], [31]. The modular tier design supports incremental deployment. A utility can deploy only Tier 1 (S-Trees for threat detection) as a low-risk first step, then add Tier 2 (E-Trees for forecasting) to enable proactive BESS pre-positioning, and finally activate Tier 3 (DRL agent with RCPM) for fully autonomous control once the utility has built operational confidence in Tiers 1 and 2. This deployment pathway reduces integration risk and allows phased regulatory approval.

Multi-Agent Extensions

The current DNF is a centralised single-agent controller. For large grid operators managing multiple independent control zones, a multi-agent extension is desirable: each zone runs its own DRL agent coordinated by a shared global state representation. Prior multi-agent L2RPN results [29] suggest that centralised training with decentralised execution (CTDE) achieves near-optimal coordination while respecting the communication constraints of real control zones. We have begun preliminary experiments with the CTDE framework applied to the DNF's multi-zone extension on a six-zone variant of the IEEE 39-bus system. Federated learning offers an alternative coordination mechanism that avoids sharing raw operational data across zones — a significant practical concern given NERC CIP data handling requirements. In the federated DNF, each zone trains its own DRL agent locally and shares only gradient updates (not data) with a central coordinator at the end of each training batch. Preliminary results indicate that federated training reaches 94% of the centralised BOS within 2× the training compute, a reasonable overhead for the privacy and compliance benefits [29], [30], [35].

Related Work: Multi-Objective Rl and Grid Autonomous Control

Multi-Objective Reinforcement Learning Foundations

Multi-objective RL (MORL) formalises decision problems where the reward signal has multiple competing components. Two principal approaches exist: scalarisation methods, which combine objectives into a weighted sum before applying single-objective RL algorithms; and Pareto-front methods, which learn a set of policies, each optimal for a different objective weighting. The DNF uses dynamic scalarisation — a weighted sum with time-varying weights — to bridge these two approaches: it approximates the Pareto frontier's knee point (the point of maximum balanced performance) by continuously adjusting weights in response to the current threat level [5], [26].

Static scalarisation methods fail the DNF's requirements because the optimal weighting changes with operating conditions: during a high-threat event, security should dominate ($\lambda \rightarrow 1$); during normal operation, sustainability should dominate ($\lambda \rightarrow 0$). A fixed weighting inevitably over-weights one objective for at least half of the operating time. The dynamic weighting mechanism — driven by a sigmoid function of the S-Tree threat probability — provides a principled, physics-grounded adaptation rule that the DRL agent learns to anticipate, effectively planning ahead for the impending weighting shift when threat probability rises [5], [18]. Liu et al.'s Linear Scalarisation DRL [29] is the most directly comparable MORL baseline. Their approach used three fixed weighting vectors sampled from the objective simplex and trained three separate DQN agents, one per weighting. At test time, the weighting with the best historical performance was selected. This approach requires 3× the training compute and cannot respond to mid-episode threat-level changes that shift the optimal weighting between the three pre-trained options. The DNF's single-agent dynamic weighting outperforms the best Lin et al. policy in 43 of 50 evaluation episodes [5], [29].

Autonomous Grid Control: Industry Perspectives

Despite significant academic progress, autonomous grid control has seen limited production deployment to date. The primary obstacles are regulatory: NERC FAC-001 and FAC-002 require facilities to operate within defined steady-state and stability limits at all times; the obligation to meet these limits ultimately rests with the human operator, creating liability uncertainty when control is delegated to an autonomous agent. The RCPM's hard constraint checker directly addresses this: by verifying each recommended action against the FAC-001/002 limits before execution, the RCPM ensures that the autonomous system only issues commands that a trained operator would be permitted to issue [9], [31]. Several transmission operators have publicly described pilots with AI-assisted (not fully autonomous) grid control. National Grid ESO in the UK deployed a machine learning-based frequency response procurement system in 2022 that recommends BESS pre-commitment positions to operators, who retain final approval. PJM Interconnection has piloted ML-based contingency analysis that flags high-risk switching sequences before operators execute them. Both pilots are in the 'decision support' category — the AI makes recommendations, humans decide. The DNF's architecture is designed to support both the advisory mode (RCPM provides recommended actions for human approval) and the autonomous mode (RCPM executes approved actions directly), enabling phased deployment from advisory to autonomous as operational confidence grows [9], [30], [31].

Digital Twins for DRL Training and Validation

High-fidelity digital twins of power systems provide an ideal training environment for DRL agents. Unlike simplified simulation models, digital twins capture the dynamic behaviour of protection systems, automatic generation control, and voltage regulation equipment — all of which interact with the control actions the DNF agent issues. Training in a digital twin rather than a simplified simulation has been shown to improve policy transfer to the physical system by 30–40% in robot control domains, and preliminary power systems results are consistent with this finding [29]. The DNF's E-Tree forecasters can also be calibrated against digital twin outputs, providing ground-truth forecast targets with higher fidelity than the ns-3 co-simulation used in this paper. A digital twin calibration study is planned for a follow-on paper, in collaboration with a transmission operator whose real-time digital twin is built on the PSCAD/EMTDC platform. The expected benefit is 5–10% improvement in E-Tree forecast accuracy for fast-dynamics events (sudden cloud cover, wind ramps), which are the scenarios where the current forecaster's physics regularisation term is most beneficial [22], [29], [30].

ABSTRACT

Ambulation during labor is thought to positively influence maternal and neonatal outcomes, yet evidence remains inconsistent. This study aimed to evaluate the effects of ambulation on maternal and neonatal outcomes among primigravida mothers during the first stage of labor. A Quasi- experimental Posttest-only control group design was employed at the Obstetrics and Gynecology departments in hospitals of Kheda-Anand district of Gujarat. The study included (n=60) primigravida mothers were selected via computer assisted sampling group for intervention (n=30) and a control group (n=30).The intervention group was encouraged to ambulate during the first stage of labor, walking for 20 minutes followed by 10 minutes of rest in the left lateral position, repeated six times until full cervical dilation. The control group received routine hospital care. Data were collected using a demographic interview schedule, WHO Partograph, and APGAR scores. Statistical analysis was performed using an independent t-test and analysis of variance. Ambulation during the first stage of labor significantly improved maternal labor outcomes. A higher proportion of mothers in the ambulation group completed the first stage of labor within 8–12 hours ($p = 0.002$), experienced a shorter second stage of labor ($p < 0.01$), and had a higher rate of cervical dilatation ($p < 0.05$) compared to the control group. No significant differences were observed regarding rupture of membranes or mode of delivery ($p > 0.05$). Neonatal outcomes, assessed by APGAR scores at 1 and 5 minutes, were comparable between the groups, with the majority of neonates achieving excellent APGAR scores and no statistically significant differences observed ($p > 0.05$). Ambulation

during the first stage of labor is a safe and effective intervention that shortens labor duration and improves labor progress without adversely affecting neonatal outcomes. It may be encouraged as a routine practice to promote favorable maternal and neonatal outcomes.

Keywords: Ambulation, Active Birth, Primigravida, Maternal Outcomes, Neonatal Outcomes

INTRODUCTION

Labor is a physiological process that culminates in the birth of a baby and is influenced by several maternal, fetal, and environmental factors. The first stage of labor, extending from the onset of regular uterine contractions to full cervical dilatation, plays a crucial role in determining maternal comfort, labor progress, and neonatal outcomes. Traditionally, women in labor have often been confined to bed in a supine or semi-recumbent position, despite growing evidence suggesting that freedom of movement and upright positions may facilitate labor progress and improve childbirth experiences. [1] Ambulation, defined as walking or maintaining an upright position during labor, is a simple, non-pharmacological intervention that promotes physiological childbirth. Ambulation utilizes gravity to enhance fetal descent, improves uterine contractions, increases pelvic dimensions, and may accelerate cervical dilatation, thereby shortening the duration of labor.[2] In addition, allowing women to move freely during labor has been associated with increased maternal comfort, reduced pain perception, and greater satisfaction with the childbirth experience.[3] The World Health Organization recommends encouraging mobility and upright positions during labor for women at low risk of complications, emphasizing respect for women's preferences and the promotion of positive childbirth experiences.[4] However, despite these recommendations, routine labor practices in many healthcare settings continue to restrict maternal mobility, particularly among primigravida mothers who are more likely to experience prolonged labor and increased anxiety during childbirth.[5]

Several published studies have supported the beneficial effects of ambulation on maternal outcomes during labor. A systematic review involving more than 5,000 women reported that upright positions and walking during the first stage of labor were associated with a reduction in the duration of labor by approximately one hour and improved maternal satisfaction without increasing the risk of cesarean delivery or adverse maternal outcomes.[3] Similarly, women who remained mobile and adopted upright positions experienced shorter first-stage labor and were less likely to require epidural analgesia compared with women confined to recumbent positions.[6] A prospective study demonstrated that ambulation during the active phase of labor significantly accelerated cervical dilatation and shortened the duration of the first stage among primigravida women.[7] Likewise, women who were encouraged to walk and change positions during labor experienced lower pain scores, greater comfort, and a more positive childbirth experience compared with women who remained in bed.[8] A systematic review and meta-analysis also concluded that maternal mobility during labor was associated with improved labor progress and reduced intervention rates, supporting the promotion of ambulation as a safe and effective practice.[9] Furthermore, walking, moving freely, and changing positions throughout labor have been recognized as evidence-based practices that enhance maternal comfort, facilitate fetal descent, and contribute to a more physiologic birth process.[10] These findings collectively suggest that ambulation is a beneficial, low-cost intervention that can positively influence maternal outcomes during labor while preserving maternal autonomy and satisfaction. However, restricted mobility during labor is still commonly practiced in many healthcare settings. This gap between evidence and practice motivated the investigator to undertake the present study. In view of the above, the present study aimed to evaluate the effectiveness of ambulation during the first stage of labor on maternal and neonatal outcomes among primigravida mothers.

MATERIALS AND METHODS

This study employed a quantitative research approach with a quasi-experimental design to evaluate the effectiveness of ambulation during the first stage of labor on selected maternal and neonatal outcomes among primigravida mothers. The study was conducted in selected hospitals of Kheda–Anand District, Gujarat, India. The target population comprised primigravida mothers admitted in labor. A total of 60 participants were included in the study, with 30 mothers assigned to the experimental group and 30 mothers to the control group. Participants were selected using a convenience sampling technique based on the predefined inclusion criteria.The study was carried out over a period from December 2021 to November 2022.

The inclusion criteria were: 1) Primigravida mothers (first pregnancy); 2) Single fetus with cephalic presentation; 3) Gestational age between 36 to 41 weeks; 4) Cervical dilation between 3 to 5 cm; 5) No known pregnancy complications or risk factors; 6) Willingness to adopt the Ambulation during the first stage of labor; and 7) Undergoing spontaneous vaginal delivery at term. Exclusion criteria included: 1) Multiparous mothers; 2) Multiple gestations; 3) High-risk conditions such as preeclampsia, gestational diabetes, precipitate labor, placenta previa, or known fetal anomalies; 4) Induced Labour 5) Cesarean deliveries (elective or emergency); 6) Any condition limiting the ability to maintain the Ambulation and 7) Non-consent or withdrawal from the study.In the Ambulation group, participants in the ambulation group were encouraged to ambulate for 20 minutes, followed by a 10-minute rest period in the left lateral position during the active phase of the first stage of labor, before full cervical dilatation.The intervention began when the mother reached 3-5 cm of cervical dilation, with the ambulation intervention was initiated at the onset of the active phase of the first stage of labor and continued until full cervical dilatation (10 cm) was achieved.

During the intervention period, ambulation was initiated at the onset of the active phase of the first stage of labor and continued until full cervical dilatation (10 cm) was achieved. Following the collection of baseline demographic and obstetric data and obtaining written informed consent, primigravida mothers in the ambulation group were encouraged to ambulate for 20 minutes, followed by a 10-minute rest period in the left lateral position. This cycle of ambulation and rest was repeated throughout the first stage of labor until complete cervical dilatation was attained. Maternal and fetal conditions were continuously monitored throughout the intervention to ensure the safety and well-being of both mother and fetus.This cycle was repeated six times until full cervical dilation was achieved. Once full dilation was confirmed, the mother was shifted to the labor bed .Uterine contractions were assessed using abdominal palpation by evaluating the hardness of the fundal area during contractions. Additionally, the intensity was assessed based on the mother's subjective experience of pain and pressure. Both findings were systematically recorded using the WHO Partograph. Labor progression was monitored using observation methods, and cervical dilation was evaluated by the obstetrician through per vaginal (PV) examinations every 6 hours. The status of the rupture of membranes, whether spontaneous or artificial, was also observed and recorded.

All findings were documented using a modified WHO Partograph. For neonatal outcomes, the Apgar score was checked at 1 minute and 5 minutes after birth in collaboration with the pediatrician and staff nurse. Additionally, any need for assistance, such as NICU admission, was evaluated. Post-test evaluations were conducted during the labor process and after delivery to measure both maternal and neonatal outcomes. The maternal outcomes assessed were duration of all three stages of labor, cervical dilation, intensity of uterine contractions, and rupture of membranes; while neonatal outcomes included APGAR score, weight of the baby and the need for resuscitation or NICU admission. The findings of the study demonstrated that ambulation during the first stage of labor was effective in significantly improving maternal outcomes among primigravida mothers. Women in the ambulation group experienced a shorter mean duration of the first stage of labor (9.8 ± 1.6 hours) compared with the control group (11.1 ± 1.9 hours) and exhibited a higher mean rate of cervical dilatation (1.6 ± 0.4 cm/hour vs. 1.2 ± 0.3 cm/hour), indicating enhanced labor progress. Ambulation was also associated with stronger uterine contractions and favorable progression of labor. Although a few late preterm deliveries (36 weeks of gestation) were observed, neonatal

outcomes remained within normal healthy limits, with no adverse neonatal effects reported. These findings support ambulation as a safe, effective, and non-pharmacological intervention for improving maternal labor outcomes while maintaining favorable neonatal health during labor.

Ethical considerations

The study received approval from the Institutional Ethical Committee (Approval No. EC/767/2021) on November 23, 2021. All participants were informed about the study's objectives and the interventions used. Initially, coding was performed, and informed consent was obtained from each participant. Participants were assured of confidentiality and were informed of their right to withdraw from the study at any time during data collection.

Data analysis

The collected data were coded and analyzed using IBM SPSS Statistics for Windows, version 20.0. Descriptive statistics, including frequency, percentage, mean, and standard deviation, were used to summarize the demographic, maternal, and neonatal characteristics of the participants. For inferential statistics, Levene's test was used to assess the equality of variances, followed by the Independent Samples t-test to compare maternal and neonatal outcomes between the ambulation and control groups.The significance level was set at $P \leq 0.05$.

RESULTS

Frequency and Percentage Distribution of Demographic Variables among Primigravida Mothers in the Ambulation and Control Groups In the ambulation group, the majority of primigravida mothers were aged 26–29 years (43.3%), followed by 22–25 years (36.7%), while 10% each belonged to the 18–21 years and above 30 years age groups. Most mothers had secondary education (33.3%), followed by primary education and graduation (30% each). Half of the mothers were employed in the private sector (50%), whereas 23.4% were housewives. The majority of participants were Hindus (50%), resided in rural areas (56.7%), and belonged to nuclear families (63.3%). Most mothers followed a vegetarian diet (73.4%) and did not perform regular exercise (73.3%). Mothers (40%) and sisters (33.3%) were the most common support persons during labor. The majority of mothers reported using complementary and alternative medicine for easy labor (93.3%). Medical augmentation of labor was required in 30% of mothers, and among them, oxytocin was the most commonly administered drug (77.8%), followed by prostaglandin (22.2%). In the control group, most primigravida mothers were aged 22–25 years (43.3%), followed by 26–29 years (36.7%). The majority had secondary education (36.7%) or were graduates (30%). Half of the mothers were housewives (50%), and 26.6% were employed in the private sector. Most participants were Hindus (53.3%), resided in rural areas (63.4%), and belonged to nuclear families (53.4%). A large proportion followed a vegetarian diet (86.7%) and did not engage in regular exercise (83.4%). Mothers and sisters were the most common support persons during labor (40% each). The majority used complementary and alternative medicine for easy labor (96.4%). Medical augmentation of labor was required in 33.3% of mothers, with oxytocin being the most frequently used drug (80%), followed by prostaglandin (20%).

Frequency and percentage distribution of clinical variables of Primigravida mothers in the Ambulation and Control Groups

The clinical characteristics of the participants revealed that the majority of mothers in the ambulation group had a normal BMI during the first trimester (56.6%), while in the control group, 46.6% had a normal BMI. Most mothers in both groups had a gestational age of 38–39 weeks (46.6% in the ambulation group and 40% in the control group). Regarding cervical dilatation at enrollment, the majority of mothers were in the active phase of labor, accounting for 46.6% in the ambulation group and 40% in the control group. Concerning neonatal birth weight, most newborns weighed between 2.6 and 3.0 kg, representing 53.3% in the ambulation group and 66.7% in the control group, followed by 3.1–3.5 kg in 36.6% and 20% of newborns, respectively.

Analysis of Labor Outcome among Primigravida Mothers in Ambulation and Control Groups:

The findings demonstrated that ambulation was effective in improving maternal outcomes among primigravida mothers. A statistically significant reduction was observed in the duration of the first stage of labor lasting 8–12 hours (t=3.333, p=0.002), the second stage of labor lasting less than 1 hour (t=–2.812, p=0.007), and the total duration of labor lasting 8–12 hours (t=3.333, p=0.002) in the ambulation group compared with the control group. The rate of cervical dilatation was significantly higher among mothers who ambulated, with a greater proportion achieving cervical dilatation of more than 1 cm/hour (t=-4.125, p<0.001) and 1 cm/hour (t=2.154, p=0.035). No significant differences were observed regarding rupture of membranes or mode of delivery (p>0.05). These findings indicate that ambulation effectively promotes labor progress and improves maternal outcomes during the first stage of labor.

Analysis of Neonatal Outcome among Primigravida Mothers in Ambulation and Control Groups

The findings showed that neonatal outcomes, assessed using APGAR score categories at 1 and 5 minutes after birth, were comparable between the ambulation and control groups. No statistically significant differences were observed at either 1 minute (t = 1.523, p = 0.133) or 5 minutes (t = 0.584, p = 0.561), indicating that ambulation during the first stage of labour had no significant effect on the immediate neonatal condition of newborns.

DISCUSSION

The present study demonstrated that ambulation during the active phase of the first stage of labour significantly improved maternal outcomes among primigravida mothers. Women in the ambulation group experienced a significantly shorter first stage of labour (t = 3.333, p = 0.002), second stage of labour (t = -2.812, p = 0.007), and total duration of labour (t = 3.333, p = 0.002). In addition, the rate of cervical dilatation was significantly higher among mothers who ambulated (p< 0.001). However, no significant differences were observed in rupture of membranes, mode of delivery, or neonatal outcomes, with APGAR scores at 1 minute (p = 0.133) and 5 minutes (p = 0.561) remaining comparable between the ambulation and control groups. These findings suggest that ambulation promotes physiological labour without compromising neonatal well-being. The present findings are consistent with the Cochrane review by Lawrence et al. (2013), which included 25 randomized controlled trials involving 5,218 women and concluded that upright positions and ambulation during the first stage of labour significantly reduced labour duration by approximately 1 hour and 22 minutes, without increasing the risk of caesarean section, instrumental delivery, or adverse neonatal outcomes.[11] Similarly, Bloom et al. (1998), in a randomized trial of 1,067 low-risk women, reported that walking during labour had no significant effect on APGAR scores, mode of delivery, or other neonatal outcomes, supporting the safety of maternal ambulation.[12]

The findings are further supported by the World Health Organization (2018), which recommends encouraging women with uncomplicated pregnancies to remain mobile and adopt positions of their choice during labour to facilitate normal labour progression and improve the childbirth experience.[13] The present study adds evidence from an Indian setting by demonstrating that structured ambulation significantly enhances labour progress while maintaining favourable neonatal outcomes among primigravida mothers. A notable strength of the present study is the simultaneous evaluation of both maternal and neonatal outcomes in a controlled comparison. The findings support ambulation as a simple, low-cost, and non-pharmacological nursing intervention that can be incorporated into routine intrapartum care to promote physiological labour without increasing maternal or neonatal risk.

Limitations of the Study

The present study has a few limitations that should be considered while interpreting the findings. The study was conducted among only 60 primigravida mothers from selected hospitals in the Kheda–Anand district of Gujarat, which may limit the generalizability of the results. The intervention was implemented primarily by the principal investigator with the assistance of labour room staff, which may have introduced minor variations in its implementation. The duration and frequency of ambulation depended on each mother's comfort, pain tolerance, and

labour progression, making complete standardization difficult. The study included only low-risk primigravida mothers, limiting the applicability of the findings to multigravida women and high-risk pregnancies. Neonatal outcomes were assessed only using APGAR scores at 1 and 5 minutes, without evaluating long-term neonatal outcomes. Additionally, the intervention was compared with routine labour care rather than another standardized mobility intervention. Future multicentre studies with larger sample sizes are recommended to enhance the generalizability and strengthen the evidence regarding the effectiveness of ambulation during labour.

CONCLUSION

The findings of the present study demonstrate that ambulation during the active phase of the first stage of labour is an effective and safe non-pharmacological intervention for primigravida mothers. Ambulation significantly improved maternal outcomes by reducing the duration of labour and increasing the rate of cervical dilatation without adversely affecting neonatal outcomes. The intervention was simple, feasible, and well-tolerated in the clinical setting. Therefore, ambulation can be recommended as a routine nursing practice for low-risk primigravida mothers to promote physiological labour and support positive maternal and neonatal outcomes.

ABSTRACT

Dental health conditions such as dental caries, gingivitis, and periodontitis are common oral health problems that can negatively affect an individual's health and quality of life. Early prediction of these conditions can support timely intervention and preventive care. Machine learning (ML) techniques provide an effective means of analysing demographic, behavioural, lifestyle, and clinical factors associated with dental health. However, the presence of irrelevant and redundant features can affect model efficiency and prediction performance. This study proposes a feature selection-based machine learning framework for enhanced prediction of dental health conditions. The proposed framework involves data preprocessing, feature selection, machine learning model development, and performance evaluation. Decision Tree, Random Forest, Support Vector Machine (SVM), and Extreme Gradient Boosting (XGBoost) algorithms are considered for comparative analysis. The models are evaluated using Accuracy, Precision, Recall, F1-Score, and Receiver Operating Characteristic–Area Under the Curve (ROC-AUC). The proposed framework focuses on identifying the most relevant features and determining the machine learning model that provides the most effective prediction performance. The study aims to develop an efficient and interpretable approach for dental health prediction that can support early identification of individuals at risk and assist clinical decision-making.

Keywords: Dental Health Prediction; Machine Learning; Feature Selection; Dental Caries; Classification; Random Forest; Support Vector Machine; XGBoost

INTRODUCTION

Oral health is an important component of overall health and quality of life. Dental caries and other oral health conditions can cause pain, discomfort, tooth loss, and difficulties in eating when they are not identified and managed at an early stage. Therefore, early identification of individuals who are at risk of developing dental health conditions is important for supporting timely preventive and clinical interventions. Machine learning (ML) has increasingly been applied in healthcare because of its ability to identify patterns from demographic, behavioural, lifestyle, and clinical data. In dental research, ML techniques have been investigated for disease prediction, risk assessment, diagnosis, and clinical decision support. (Ahmed et al., 2021; Schwendicke et al., 2020; Arsiwala-Scheppach et al., 2023). Reyes et al. (2022) reported that ML methods have considerable potential for the diagnosis and prognostic prediction of dental caries, although the quality of datasets, validation procedures, and methodological design remain important considerations.Recent research has also demonstrated the usefulness of ML for identifying dental disease risk from patient-related factors. Çiftçi and Aşantoğrol (2024) evaluated several ML algorithms for predicting caries risk groups using demographic, behavioural, and clinical information. Their findings demonstrated that factors such as age, body mass index, tooth-brushing frequency, diabetes, and consumption of sugary foods were associated with caries risk, highlighting the value of combining multiple patient-related variables for prediction.

Feature selection is particularly important when healthcare datasets contain a large number of variables. Selecting relevant features can reduce redundant information, simplify the predictive model, and improve computational efficiency. Kang et al. (2023) developed a dental caries prediction model incorporating feature selection and demonstrated the usefulness of selecting informative variables before applying machine learning algorithms (Kang et al., 2023; Guyon & Elisseeff, 2003; Hall, 1999). Similarly, Ogwo et al. (2024) used machine learning to predict dental caries outcomes in young adults and examined a broad range of demographic, dietary, behavioural, and previous caries-related variables. Their study identified previous caries experience and sugar-sweetened beverage consumption among the important predictors, demonstrating the potential of ML to identify influential factors from multiple variables (Ogwo et al., 2024; Prados-Privado et al., 2020). Although existing studies have demonstrated the potential of machine learning in dental health prediction, there remains a need for an efficient framework that systematically selects relevant features before comparing different prediction algorithms. Therefore, this study proposes a Feature Selection-Based Machine Learning Framework for Enhanced Prediction of Dental Health Conditions. The proposed framework integrates data preprocessing, feature selection, machine learning model development, and performance evaluation. The study focuses on identifying relevant predictors and determining an effective machine learning model for dental health prediction.

LITERATURE REVIEW

Recent advances in machine learning have created new opportunities for predicting dental health conditions using clinical, demographic, behavioural, and lifestyle information. Researchers have investigated different machine learning and deep learning approaches for dental caries detection, risk prediction, and clinical decision support. The findings of these studies indicate that machine learning can identify relevant patterns in dental health data and support early prediction (Ahmed et al., 2021; Schwendicke et al., 2020). Recent scoping evidence also shows that machine learning is being increasingly applied across multiple areas of dentistry, while differences in datasets, modelling approaches, and reporting practices can make comparison and reproducibility challenging (Arsiwala-Scheppach et al., 2023). Reyes et al. (2022) conducted a systematic review of machine learning applications in the diagnosis and prognostic prediction of dental caries. Their review reported that machine learning methods showed promising performance across different dental datasets and diagnostic tasks. However, the authors highlighted the importance of appropriate datasets, methodological consistency, and external validation for developing reliable prediction models (Reyes et al., 2022). Mohammad-Rahimi et al. (2022) reviewed the application of deep learning techniques for dental caries detection. Their findings demonstrated the potential of deep learning for identifying caries-related patterns from dental images. However, variations in datasets, image acquisition procedures, and

evaluation methods remain challenges when developing models that can generalize across different clinical settings (Mohammad-Rahimi et al., 2022; Prados-Privado et al., 2020). Kang et al. (2023) proposed a dental caries prediction model based on machine learning and feature selection. The study demonstrated that selecting informative features can improve prediction performance while reducing the number of variables required by the model. This finding is particularly relevant to the present study because feature selection can simplify the prediction process and reduce the influence of less informative variables (Kang et al., 2023; Guyon & Elisseeff, 2003).

Çiftçi and Aşantoğrol (2024) investigated machine learning models for predicting caries risk groups and oral-health-related risk factors among adults. Their study considered demographic, behavioural, and health-related variables and demonstrated the usefulness of machine learning for identifying individuals with different levels of caries risk. The study also showed that patient-related factors can provide valuable information for dental health prediction (Çiftçi &Aşantoğrol, 2024). Ogwo et al. (2024) examined machine learning approaches for predicting dental caries outcomes among young adults. Their study incorporated demographic, dietary, behavioural, and previous caries-related information. The findings indicated that machine learning could identify important predictors associated with dental caries and could potentially support preventive oral healthcare (Ogwo et al., 2024). Recent studies have also investigated artificial intelligence for dental caries detection using radiographic and photographic data. These studies demonstrate the potential of AI-assisted approaches while also highlighting the importance of dataset quality, image characteristics, and external validation (Albano et al., 2024; Ammar &Kühnisch, 2024; Moharrami et al., 2024; Negi et al., 2024). The reviewed studies demonstrate that machine learning has considerable potential for dental health prediction. However, differences in datasets, input variables, prediction targets, and modelling approaches make direct comparison between existing studies difficult. In addition, several studies focus on a specific dental condition or image-based diagnosis, whereas fewer studies investigate a systematic feature selection process followed by comparative evaluation of multiple machine learning algorithms using patient-related information (Revilla-León et al., 2022; Arsiwala-Scheppach et al., 2023). Therefore, there is a need for a simple and systematic framework that identifies the most relevant features before developing prediction models. The present study addresses this need by integrating data preprocessing, feature selection, machine learning classification, and performance evaluation within a single framework for enhanced dental health prediction.

Research Gap

Existing studies demonstrate the growing potential of machine learning for dental health prediction. However, several limitations can be identified from the recent literature. First, many studies focus on a specific dental condition, particularly dental caries, rather than developing a broader prediction framework for dental health conditions. Second, several studies use a relatively large number of demographic, behavioural, and clinical variables without systematically determining which features contribute most to prediction. The inclusion of irrelevant or redundant variables may increase model complexity and affect prediction performance (Reyes et al., 2022; Çiftçi & Aşantoğrol, 2024; Ogwo et al., 2024). Third, existing research often evaluates individual machine learning algorithms or focuses on a particular modelling approach. A systematic comparison of different machine learning algorithms after feature selection is less frequently addressed. Such a comparison is important for determining whether reducing the feature space can maintain or improve prediction performance across different classification algorithms (Kang et al., 2023; Arsiwala-Scheppach et al., 2023). Fourth, previous studies have used different datasets, populations, input variables, and evaluation procedures, making it difficult to identify a consistent set of predictors for dental health conditions. In addition, some research is primarily based on dental images, whereas patient-related demographic, lifestyle, behavioural, and clinical information can provide complementary information for risk prediction (Mohammad-Rahimi et al., 2022; Albano et al., 2024; Moharrami et al., 2024; Negi et al., 2024).

Based on these limitations, a research gap exists in developing a simple and systematic feature selection-based framework that identifies relevant patient-related features and evaluates multiple machine learning algorithms using the selected features. Addressing this gap can improve model efficiency, reduce unnecessary variables, and provide better insight into the factors associated with dental health prediction (Guyon & Elisseeff, 2003; Hall, 1999). Therefore, the present study focuses on developing a Feature Selection-Based Machine Learning Framework for

Enhanced Prediction of Dental Health Conditions. The framework integrates data preprocessing, feature selection, machine learning classification, and comparative performance evaluation to identify an effective prediction approach.

Problem Statement

Dental health conditions can develop gradually and may remain undetected until noticeable symptoms appear. Conventional dental assessment depends mainly on clinical examination and diagnostic procedures, which may make continuous risk assessment difficult when large amounts of patient-related information are involved. The increasing availability of demographic, behavioural, lifestyle, and clinical data provides an opportunity to develop computational approaches for early prediction of dental health conditions (Ahmed et al., 2021; Schwendicke et al., 2020). Machine learning can analyse multiple patient-related factors and identify patterns associated with dental health outcomes. However, dental datasets may contain irrelevant, redundant, or weakly informative features. Using all available features can increase model complexity, computational requirements, and the possibility of reduced predictive performance. Furthermore, different machine learning algorithms may respond differently to the selected input features (Guyon & Elisseeff, 2003; Hall, 1999). Therefore, the problem addressed in this study is the development of an efficient machine learning framework that can identify the most relevant features and use them to improve the prediction of dental health conditions. The study aims to address this problem through systematic data preprocessing, feature selection, comparative machine learning modelling, and performance evaluation.

Research Objectives

The objectives of this study are:

- To collect and preprocess demographic, behavioural, lifestyle, and clinical data relevant to dental health conditions.
- To identify the most relevant features for dental health prediction using an appropriate feature selection technique.
- To develop machine learning classification models using the selected features.
- To compare the performance of different machine learning algorithms for predicting dental health conditions.
- To evaluate the developed models using Accuracy, Precision, Recall, F1-Score, and ROC-AUC.
- To identify the most influential features associated with dental health prediction and provide an interpretable basis for the developed machine learning framework.

PROPOSED METHODOLOGY

The proposed methodology presents a systematic machine learning framework for predicting dental health conditions using relevant patient-related features. The framework consists of data collection, data preprocessing, feature selection, machine learning model development, and performance evaluation. The objective is to identify the most informative features and determine an effective machine learning model for dental health prediction.

Overall Framework

The proposed framework begins with the collection of dental health data containing demographic, behavioural, lifestyle, and clinical attributes. The collected data are preprocessed to improve their quality and consistency. Feature selection is then performed to identify the most relevant attributes and reduce unnecessary information. The selected features are used to train different machine learning models, including Decision Tree, Random Forest, Support Vector Machine (SVM), and Extreme Gradient Boosting (XGBoost). Finally, the developed models are evaluated using standard classification metrics to determine their

Data Preprocessing

The collected dental health dataset is preprocessed to improve data quality and prepare the data for machine learning analysis. The preprocessing stage includes checking for missing values, removing duplicate records,

encoding categorical variables, and preparing numerical attributes for analysis. Categorical variables are converted into suitable numerical representations, while numerical features are standardized when required. These preprocessing steps help maintain consistency among the input variables and reduce potential errors during model training. After preprocessing, the dataset is divided into training and testing sets for model development and performance evaluation **(**Pedregosa et al., 2011).

Feature Selection

Feature selection is performed to identify the most relevant attributes for predicting dental health conditions. Dental health datasets may contain features that provide limited information or duplicate information provided by other variables. Including such features may increase model complexity and affect prediction performance. Therefore, the feature selection stage removes less informative attributes while retaining the features that contribute meaningfully to the prediction task. Feature selection can reduce unnecessary variables, improve computational efficiency, and support the interpretation of predictive models (Guyon & Elisseeff, 2003; Hall, 1999). The selected features are subsequently used as inputs for all machine learning models to ensure a consistent and fair comparison.

Machine Learning Models

The selected features are used as input variables for developing and comparing different machine learning models. Four supervised learning algorithms, namely Decision Tree (DT), Random Forest (RF), Support Vector Machine (SVM), and Extreme Gradient Boosting (XGBoost), are considered in this study because they represent different classification and ensemble learning approaches (Quinlan, 1986; Breiman, 2001; Cortes &Vapnik, 1995; Chen &Guestrin, 2016). These algorithms are selected because they represent different classification approaches and enable a comparative evaluation of dental health prediction performance. Each model is trained using the same selected feature set and evaluated using identical experimental conditions.

Performance Evaluation

The performance of the developed machine learning models is evaluated using Accuracy, Precision, Recall, F1-Score, and Receiver Operating Characteristic–Area Under the Curve (ROC-AUC). These metrics are selected to provide a comprehensive assessment of the classification performance. Accuracy measures the proportion of correctly classified instances, while Precision indicates the proportion of predicted positive cases that are actually positive. Recall measures the ability of the model to correctly identify positive cases, and F1-Score represents the balance between Precision and Recall. ROC-AUC measures the ability of the model to distinguish between different classes across classification thresholds. These evaluation measures provide complementary information about classification performance, particularly when accuracy alone may not fully describe model behaviour (Fawcett, 2006).

The evaluation metrics are calculated using the following equations:

Accuracy

Accuracy = (TP + TN) / (TP + TN + FP + FN)

Precision

Precision = TP / (TP + FP)

Recall

Recall = TP / (TP + FN)

F1-Score

F1-Score = 2 × (Precision × Recall) / (Precision + Recall)

ROC-AUC

ROC-AUC represents the area under the Receiver Operating Characteristic (ROC) curve, which plots the True Positive Rate against the False Positive Rate at different classification thresholds.

where TP represents True Positive, TN represents True Negative, FP represents False Positive, and FN represents False Negative.

Dataset Description

The dataset used in this study contains patient-related information relevant to the prediction of dental health conditions. The selected attributes represent demographic, behavioural, lifestyle, and clinical factors that may be associated with dental health outcomes. These variables are used as input features for the proposed machine learning framework, while the dental health condition serves as the target variable. Before model development, the dataset is examined for missing values, duplicate records, inconsistent entries, and inappropriate data types. The cleaned dataset is subsequently processed and transformed into a suitable format for feature selection and machine learning analysis. The dataset consists of 1,000 instances and 12 input features representing demographic, behavioural, lifestyle, and clinical factors. The target variable represents the dental health condition, and the dataset is divided into 80% training data and 20% testing data for model development and evaluation.

Dataset Variables

The dataset includes variables representing different aspects of dental health and related patient characteristics. The variables are grouped into four major categories: demographic, behavioural, lifestyle, and clinical attributes. Demographic variables describe basic patient characteristics, while behavioural variables represent oral hygiene and dental-care practices. Lifestyle variables capture habits and dietary factors that may influence oral health. Clinical variables represent relevant health and dental conditions. These variables are considered during the feature selection stage to identify the attributes that provide the greatest contribution to dental health prediction.

Dataset Preparation

The dataset is prepared for machine learning by applying a sequence of data quality and transformation procedures. First, the collected records are examined for missing values, duplicate entries, inconsistent values, and invalid data. Missing values are handled using appropriate imputation methods based on the nature of the corresponding variable. Duplicate and invalid records are removed to avoid introducing bias into the analysis.

Categorical variables are converted into numerical representations, while numerical variables are checked for scale and distribution. Where necessary, numerical features are standardized before model training. The prepared dataset is then divided into training and testing subsets. The training data are used for feature selection and model development, while the testing data are reserved for evaluating the final prediction performance.

Feature Selection

Feature selection is an important stage of the proposed framework because the quality and relevance of input features can directly influence machine learning performance. The purpose of this stage is to identify the features that provide meaningful information for predicting dental health conditions while removing irrelevant and redundant variables. The preprocessed training dataset is analysed using an appropriate feature selection technique. The selected features are ranked or retained based on their contribution to the prediction task. Only the selected features are subsequently provided to the machine learning models. This approach reduces the dimensionality of the dataset, improves computational efficiency, and supports better interpretation of the factors associated with dental health prediction (Guyon & Elisseeff, 2003; Hall, 1999). The same selected feature set is used for all the machine learning algorithms to ensure a fair comparison of their predictive performance.

Feature Selection Technique

Mutual Information (MI) is used as the feature selection technique in the proposed framework. MI measures the amount of information shared between an input feature and the target variable. Features with higher mutual information values provide greater information about the target outcome and are therefore considered more relevant for prediction (Kraskov et al., 2004; Vinh et al., 2014). The mutual information score is calculated for each input feature using the training dataset. Features with low information scores are removed, while the most informative features are retained for model development. The selected features are then provided as input to the Decision Tree, Random Forest, Support Vector Machine, and XGBoost models. This process reduces the number of input variables while retaining the information most relevant to dental health prediction.

Feature Ranking and Selection

After calculating the mutual information scores, the features are ranked according to their relevance to the target variable. Features with higher scores are considered more informative for the prediction task. A suitable number of top-ranked features is selected based on the experimental analysis and model performance. The selected features are used as inputs for the machine learning models, while features that provide limited information are excluded. The feature ranking also helps identify the patient-related factors that contribute most to dental health prediction. The final selected features and their corresponding mutual information scores are presented in Section 11.4.

Machine Learning Model Development

After feature selection, the selected features are used to develop the machine learning models for dental health prediction. Four classification algorithms, namely Decision Tree, Random Forest, Support Vector Machine (SVM), and Extreme Gradient Boosting (XGBoost), are implemented and trained using the prepared training dataset (Quinlan, 1986; Breiman, 2001; Cortes &Vapnik, 1995; Chen &Guestrin, 2016). Each model receives the same selected feature set to ensure a fair comparison. The model parameters are configured using the training dataset, and the trained models are subsequently evaluated using the independent testing dataset. The comparative analysis helps determine which machine learning algorithm provides the most effective prediction performance for the selected dental health dataset.

Decision Tree

The Decision Tree (DT) algorithm is used as a baseline classification model for dental health prediction. It represents the decision process as a tree structure consisting of decision nodes, branches, and leaf nodes. At each decision node, the algorithm selects a feature and a corresponding decision rule to divide the data into different groups (Quinlan, 1986). The simplicity of the Decision Tree makes its predictions relatively easy to interpret. In this study, the algorithm is trained using the selected features and its classification performance is evaluated on the testing dataset. The results obtained from the Decision Tree are used as a baseline for comparison with the other machine learning models.

Random Forest

Random Forest (RF) is an ensemble learning algorithm that combines multiple Decision Trees to produce a more robust classification model. Each tree is trained using a randomly selected subset of observations and features, and the final prediction is obtained by aggregating the predictions of the individual trees (Breiman, 2001). In this study, Random Forest is applied to the selected dental health features to predict the target dental health condition. Its ensemble structure can reduce the influence of individual tree errors and improve the stability of predictions. The performance of the Random Forest model is evaluated using the same testing dataset and evaluation metrics used for the other models.

Support Vector Machine

Support Vector Machine (SVM) is a supervised machine learning algorithm used for classification tasks. It identifies an optimal decision boundary, known as a hyperplane, that separates different classes while maximizing the margin between them. Kernel functions can be used when the relationship between input features and target classes is non-linear (Cortes &Vapnik, 1995). In this study, SVM is trained using the selected dental health features to classify the target dental health condition. The trained model is evaluated using the testing dataset and the predefined performance metrics. The results are compared with those obtained from the Decision Tree, Random Forest, and XGBoost models.

Extreme Gradient Boosting

Extreme Gradient Boosting (XGBoost) is an ensemble machine learning algorithm based on the gradient boosting approach. The algorithm builds a sequence of decision trees, where each successive tree focuses on reducing the errors produced by the previous trees. This iterative learning process enables XGBoost to model complex relationships between input features and the target variable (Chen &Guestrin, 2016). In this study, XGBoost is trained

using the selected dental health features and applied to predict the target dental health condition. Its prediction performance is evaluated using the testing dataset and the predefined evaluation metrics. The results are compared with the other machine learning models to determine the most effective algorithm for the proposed framework.

Experimental Setup

The experimental setup is designed to provide a consistent environment for developing and evaluating the proposed dental health prediction framework. The preprocessed dataset is divided into training and testing subsets, with the training data used for feature selection and model development and the testing data reserved for final performance evaluation. All machine learning models are trained using the same selected features and evaluated under the same experimental conditions. The experiments are implemented using Python and appropriate machine learning libraries. The selected models are trained separately, and their predictions are evaluated using Accuracy, Precision, Recall, F1-Score, and ROC-AUC. The experimental results are recorded and compared to determine the model that provides the most effective prediction performance (Pedregosa et al., 2011). The dataset consists of 1,000 instances with 12 input features and is divided into 80% training and 20% testing subsets. The experiments are implemented using Python and appropriate machine learning libraries.

Training and Testing Procedure

The prepared dataset is divided into training and testing subsets to develop and evaluate the machine learning models. The training subset is used for feature selection and model training, while the testing subset is kept separate and used only for final performance evaluation. The same data partitioning strategy is applied to all four machine learning algorithms to ensure a fair comparison. Feature selection is performed using only the training data to avoid information leakage from the testing data. The selected features are then used to train the Decision Tree, Random Forest, Support Vector Machine, and XGBoost models. After training, the models are applied to the unseen testing data, and their predictions are recorded for performance evaluation. The training and testing subsets contain 800 and 200 instances, respectively. The trained models are evaluated on the independent testing subset, and their performance is reported using Accuracy, Precision, Recall, F1-Score, and ROC-AUC.

RESULTS AND DISCUSSION

The results of the proposed feature selection-based machine learning framework are presented after completing the experimental evaluation. The performance of the Decision Tree, Random Forest, Support Vector Machine, and XGBoost models is compared using Accuracy, Precision, Recall, F1-Score, and ROC-AUC. The analysis focuses on identifying the model that provides the most effective overall performance and examining the contribution of the selected features to dental health prediction. All numerical results reported in this section are obtained from the experimental evaluation performed using the prepared dataset.

Model Performance Comparison

The performance of the four machine learning models was evaluated using Accuracy, Precision, Recall, F1-Score, and ROC-AUC. All models were trained using the selected features and evaluated using the same testing dataset to ensure a consistent comparison. The experimental results are presented in Table 4. Among the evaluated models, the Support Vector Machine (SVM) achieved the highest Accuracy of 75.50%, followed by Random Forest with 74.50%, XGBoost with 72.00%, and Decision Tree with 71.00%. SVM also achieved the highest Precision of 69.23%, indicating better identification of positive predictions compared with the other evaluated models. Random Forest achieved the highest ROC-AUC value of 75.34%, indicating comparatively better discrimination between the target classes across different classification thresholds. The Recall values ranged from 12.96% to 31.48%, while the F1-Score values ranged from 21.54% to 36.96%. These variations indicate that the performance of the models differs according to the evaluation metric considered.

Overall, SVM provided the highest Accuracy and Precision among the evaluated models, whereas Random Forest achieved the highest ROC-AUC. Therefore, the experimental findings indicate that model selection should consider multiple evaluation metrics rather than relying only on Accuracy.

Performance Analysis

The comparative evaluation indicates that the Support Vector Machine (SVM) achieved the highest Accuracy of 75.50% among the four evaluated models. Random Forest achieved a slightly lower Accuracy of 74.50% but obtained the highest ROC-AUC of 75.34%. Decision Tree achieved an Accuracy of 71.00%, while XGBoost achieved 72.00%. The Precision results show that SVM achieved the highest value of 69.23%, followed by Random Forest at 63.64%. Decision Tree and XGBoost achieved Precision values of 44.74% and 46.15%, respectively. The Recall and F1-Score values were comparatively lower across the models, indicating that further improvement may be required for reliable identification of positive dental health cases. Overall, the results demonstrate that no single model achieved the highest value across all evaluation metrics. SVM provided the best Accuracy and Precision, whereas Random Forest provided the best ROC-AUC. These findings demonstrate the importance of evaluating multiple performance measures when selecting a machine learning model for dental health prediction.

Selected Feature Analysis

The feature selection stage identified eight relevant attributes from the prepared dataset: Previous Caries, Brushing Frequency, Oral Hygiene Score, Diabetes, Smoking, Age, Dental Visits per Year, and Fluoride Use. Among the selected features, Previous Caries, Brushing Frequency, and Oral Hygiene Score showed comparatively higher mutual information values. Diabetes, Smoking, Age, Dental Visits per Year, and Fluoride Use were also retained as informative features. These findings indicate that previous dental disease experience and oral hygiene-related factors provide useful information for predicting dental health conditions. The selected features provide an interpretable basis for the machine learning models and demonstrate how patient-related characteristics can contribute to dental health prediction.

Feature Ranking Based on Mutual Information

Mutual information analysis was used to rank the input features according to the amount of information they provide about the target dental health condition. The results showed that Previous Caries obtained the highest mutual information score (0.0424), followed by Brushing Frequency (0.0413) and Oral Hygiene Score (0.0231). Diabetes, Smoking, Age, Dental Visits per Year, and Fluoride Use also provided measurable information and were retained as selected features (Kraskov et al., 2004; Vinh et al., 2014). The remaining variables, including Sugar Intake per Day, Plaque Index, BMI, and Flossing, obtained comparatively lower mutual information scores and were not included among the selected features. The ranking demonstrates the role of feature selection in reducing the number of input variables while retaining the attributes that provide greater information for dental health prediction

Model Performance Visualization

The comparative performance of the four machine learning models is further analysed using the evaluation metrics obtained from the testing dataset. Accuracy, Precision, Recall, F1-Score, and ROC-AUC provide different perspectives of model performance. A visual comparison of these metrics helps identify the relative strengths and limitations of the evaluated models. The results indicate that Support Vector Machine achieved the highest Accuracy and Precision, while Random Forest achieved the highest ROC-AUC. Decision Tree obtained the highest Recall and F1-Score among the four models. XGBoost showed moderate performance across the evaluated metrics. These results demonstrate that the choice of the prediction model depends on the performance measure considered

ROC-AUC Analysis

The ROC-AUC metric is used to assess the ability of the machine learning models to distinguish between the different dental health condition classes. A higher ROC-AUC value indicates better discrimination between positive and negative classes across different classification thresholds (Fawcett, 2006). Among the evaluated models, Random Forest achieved the highest ROC-AUC of 75.34%, followed by Support Vector Machine with 73.90%, XGBoost with

67.54%, and Decision Tree with 63.03%. These results indicate that Random Forest provided the strongest class-discrimination capability among the evaluated models, although Support Vector Machine achieved the highest overall Accuracy. The ROC-AUC results demonstrate that model performance can vary depending on the evaluation criterion. Therefore, both threshold-dependent measures and threshold-independent measures should be considered when selecting an appropriate machine learning model for dental health prediction.

DISCUSSION

The experimental findings demonstrate that feature selection combined with machine learning can be used to develop a systematic approach for dental health prediction. The four evaluated models showed different levels of performance across the selected evaluation metrics, indicating that model effectiveness depends on the specific performance criterion considered. Support Vector Machine achieved the highest Accuracy of 75.50% and Precision of 69.23%, suggesting that it provided the strongest overall performance for these measures. Random Forest achieved the highest ROC-AUC of 75.34%, indicating better discrimination between the target classes. Decision Tree achieved the highest Recall of 31.48% and F1-Score of 36.96% among the evaluated models. The feature selection analysis identified Previous Caries, Brushing Frequency, and Oral Hygiene Score as the most informative features in the prepared dataset. These findings indicate that previous dental health experience and oral hygiene-related factors can provide useful information for predicting dental health conditions. The results also demonstrate that relying on a single evaluation metric may not provide a complete assessment of a prediction model. Accuracy, Precision, Recall, F1-Score, and ROC-AUC should therefore be considered together when selecting a suitable model for dental health prediction. Overall, the proposed framework provides a structured approach for reducing unnecessary features and comparing different machine learning algorithms for dental health prediction.

Limitations

This study has several limitations. First, the experimental analysis is based on a prepared synthetic dataset, and therefore the obtained performance values may not directly represent the performance of the proposed framework on real-world clinical data. Second, the dataset contains a limited set of demographics, behavioural, lifestyle, and clinical attributes, and additional dental and clinical variables may influence prediction performance. Third, the study evaluates four machine learning algorithms and one feature selection technique. Other feature selection methods, advanced ensemble models, and deep learning approaches may provide different results. Finally, the present evaluation uses a single train-test experimental setting. Further validation using larger, diverse, and clinically collected datasets is required to establish the generalizability and practical applicability of the proposed framework.

CONCLUSION

This study presented a feature selection-based machine learning framework for predicting dental health conditions using demographic, behavioural, lifestyle, and clinical attributes. The proposed framework integrates data preprocessing, mutual information-based feature selection, machine learning model development, and performance evaluation. Four machine learning algorithms, namely Decision Tree, Random Forest, Support Vector Machine, and XGBoost, were evaluated using Accuracy, Precision, Recall, F1-Score, and ROC-AUC. Among the evaluated models, Support Vector Machine achieved the highest Accuracy of 75.50% and Precision of 69.23%, while Random Forest achieved the highest ROC-AUC of 75.34%. The feature selection analysis identified Previous Caries, Brushing Frequency, and Oral Hygiene Score as important predictors within the prepared dataset. The findings demonstrate the potential of combining feature selection with machine learning for structured dental health prediction. However, the experiments were conducted using a synthetic dataset, and therefore the results should be considered preliminary. Future research will focus on validating the framework using larger real-world clinical datasets, evaluating additional feature selection and machine learning techniques, and improving model generalizability and interpretability for practical dental healthcare applications.

Table 1: Summary of Recent Machine Learning Studies in Dental Health Prediction

Study	Year	Research Focus	Approach	Key Finding
Reyes et al.	2022	Dental caries diagnosis and prognosis	Machine learning	ML shows potential for dental caries prediction and diagnosis.
Mohammad-Rahimi et al.	2022	Dental caries detection	Deep learning	Deep learning demonstrates potential for image-based caries detection.
Arsiwala-Scheppach et al.	2023	Machine learning in dentistry	Scoping review	ML is increasingly applied across dentistry, with variation in datasets, models, and evaluation practices.
Kang et al.	2023	Dental caries prediction	Feature selection and ML	Feature selection can improve prediction efficiency and performance.
Çiftçi &Aşantoğrol	2024	Caries risk prediction	Multiple ML models	Demographic, behavioural, and health-related factors contribute to caries-risk prediction.
Ogwo et al.	2024	Dental caries outcomes	Machine learning	Patient-related and behavioural factors can support dental caries prediction.
Albano et al.	2024	Radiographic caries detection	Artificial intelligence	AI shows potential for detecting caries lesions from radiographic images.
Moharrami et al.	2024	Caries detection from oral photographs	Artificial intelligence	AI can support caries detection from oral photographs.
Negi et al.	2024	AI-based caries diagnosis	Umbrella review	AI demonstrates potential for dental caries diagnosis and detection.

Table 2: Machine Learning Algorithms Used in the Study

Algorithm	Description	Purpose in the Study
Decision Tree (DT)	A tree-based classification algorithm that makes predictions through a sequence of decision rules.	To provide an interpretable baseline model.
Random Forest (RF)	An ensemble algorithm that combines multiple decision trees to produce a final prediction.	To provide a robust ensemble-based prediction model.
Support Vector Machine (SVM)	A supervised learning algorithm that determines an optimal decision boundary between classes.	To evaluate classification performance using a margin-based approach.

Extreme Gradient Boosting (XGBoost)	A gradient-boosting algorithm that builds decision trees sequentially to improve prediction performance.	To evaluate an efficient boosting-based prediction model.

Table 3: Dataset Characteristics

Characteristic	Description
Number of instances	1,000
Number of input features	12
Feature categories	Demographic, behavioural, lifestyle, and clinical
Target variable	Dental health condition
Data type	Numerical and categorical
Missing values	None
Duplicate records	None
Dataset split	80% training and 20% testing

Table 4: Comparative Performance of Machine Learning Models

Model	Accuracy	Precision	Recall	F1-Score	ROC-AUC
Decision Tree	71.00%	44.74%	31.48%	36.96%	63.03%
Random Forest	74.50%	63.64%	12.96%	21.54%	75.34%
Support Vector Machine	75.50%	69.23%	16.67%	26.87%	73.90%
XGBoost	72.00%	46.15%	22.22%	30.00%	67.54%

ABSTRACT

A novel lifetime distribution is suggested that can be used to simulate a hazard-rate function with a bathtub shape. Both the Weibull distribution and the Type 1 extreme value distribution are special examples of the suggested model, which is derived as a limiting case of the Beta Integrated Model. Another practical three-parameter generalization of the Weibull distribution is the model. One of the model's advantages is that it is simple to estimate the model parameters using a Weibull probability paper (WPP) plot, which is a technique for model identification. The WPP plot is used to characterize the model. A comparison with the exponentiated Weibull, another Weibull extension, is also described, along with a numerical example. When it comes to fitting data with a bathtub-shaped hazard-rate function, the suggested model performs well in comparison to other competing models. Customer transaction data sets are analyzed in order to demonstrate the applicability and usefulness of the proposed approaches. Based on numerical results, the maximum likelihood techniques approach is recommended for estimating the alpha power Weibull distribution's parameters and dependability characteristics.

INTRODUCTION

The Weibull distribution is widely used to describe lifetime data and phenomena with monotone failure rates. It has two specific cases: exponential and Rayleigh. The Weibull distribution's negatively and positively skewed density forms make it a potential first choice for simulating monotone hazard rates. For modeling phenomena with non-monotone failure rates, like bathtub-shaped and unimodal failure rates, which are prevalent in reliability and biological investigations, the Weibull distribution does not, however, offer a satisfactory parametric fit. The central regions of these bathtub danger curves are almost flat, and the corresponding densities have a positive anti-mode. The human mortality experience, where a high infant mortality rate quickly drops to a low, is an example of a bathtub-shaped failure rate. After that, it stays there for a number of years before increasing once more. When a disease's mortality peaks after a certain amount of time and then progressively falls, unimodal failure rates might be shown. When examining lifetime data, the two most popular distributions are the exponential and Rayleigh. These distributions have great physical interpretations and a number of useful characteristics. Regretfully, the Rayleigh distribution has an increasing failure rate, while the exponential distribution just has a constant one. Both of these distributions, which may also have a non-increasing hazard function, are generalized by the linear failure rate distribution. A new distribution that generalizes the linear failure rate distribution is presented in [1]. The popular (1) exponential distribution, (2) linear failure rate distribution, (3) generalized exponential distribution, and (4) generalized Rayleigh distribution are all generalized by this distribution. This page discusses the characteristics of this distribution. The unknown parameters' greatest likelihood estimates are acquired. The current distribution can offer a better fit than certain other well-known distributions, according to an analysis of a real data set.

A novel extension of the linear exponential distribution is the subject of this work. The generalized linear exponential distribution (GLED) is the name given to this distribution. Moments, modes, and quantiles are among the statistical qualities that are derived [3]. Additionally covered are the mean residual lifetime and the failure rate function. A simulation study is used to determine the parameters' greatest likelihood estimators. The GLED's superiority over other well-known distributions in modeling lifetime data is evaluated using actual data. This study [4] considers a new generalized linear exponential distribution (NGLED), which may be thought of as a new and more adaptable extension of the linear exponential distribution. The NGLED's statistical characteristics, including quantiles, moments, and the hazard rate function, are provided. Additionally covered are the maximum likelihood estimations (MLE) of unknown parameters. To demonstrate that the novel distribution is more adaptable and efficient than previous well-known distributions in modeling lifetime data, a simulation study and two real data analyses are conducted. One popular distribution for representing lifetime data in dependability and medical research is the linear exponential distribution. In this study, we present the Kumaraswamy linear exponential distribution, a novel four-parameter generalized variant of the linear exponential distribution. [5] Give a thorough explanation of the new distributions' mathematical characteristics. Specifically, the density, cumulative distribution, and hazard rate function of the distribution are expressed in closed form. Additionally, the moment generating function and r^{th} order moment are derived. There is discussion about estimating the unknown parameters' maximum likelihood.

A branching process produces a blend of the exponential and Harris distributions, which is the source of the Harris extended exponential. Moments, generating function, and order statistics are among the structural characteristics of the new distribution that are explored [6]. Data with an increasing or decreasing failure rate can be modeled using the new distribution. One of the additional parameters controls the hazard rate function's shape in a straightforward way. The utility of the new distribution is demonstrated through an application to an actual dataset. The application of two and three-parameter Weibull distributions in wind energy analyses is reviewed in the literature, and the comparison of the outcomes of various probability density functions used in cited papers with the frequency of the 0–2 m/s wind speed range in actual data is another area of focus [7]. The three-parameter Weibull model should be superior to the two-parameter Weibull distribution for bigger percentages of null wind speeds or wind speeds below 2 m/s. It produces more suitable findings and can be suggested as a substitute for wind energy estimation methods.

Using the proper transformation of random variables, distributions like the Simplex, Johnson SB, unit-Gamma, and unit-Logistic—all of which have support on the unit interval (0,1)—are created in accordance with the inverse-Gaussian mixed, Normal, Gamma, and Logistic distributions, respectively. These distributions can fulfill the same function as the Kumaraswamy and Beta distributions. In order to simulate data on the unit interval (0,1), [8] provide a novel two-parameter unit-Weibull distribution in this study. A few characteristics of this novel distribution are examined. The maximum likelihood estimators are almost unbiased and consistent, as demonstrated by Monte Carlo simulations. Two actual data sets are used to demonstrate the potential of this novel distribution.

The Maxwell generalized family of distributions was used to introduce the Maxwell–Weibull distribution. The suggested Maxwell-Weibull distribution's quantile, density, survival, hazard, and distribution functions were established. We deduced its statistical features. Its parameters were estimated using the maximum likelihood approach. To show the potentiality of the maximum likelihood estimates, a simulation exercise was conducted. The effectiveness of the suggested Maxwell–Weibull distribution was evaluated using two lifespan data sets [9]. In comparison to the other competing distributions, we found that the Maxwell-Weibull distribution was best suited for the end-of-year selling of Nigerian Naira to Japanese Yen exchange rates and glass fiber strengths data sets. This is because it has the highest log-likelihood value and the lowest values of statistical criteria such as AIC, CAIC, and HQIC. To increase the flexibility and potentiality of a family of distributions, a novel technique for adding an additional parameter has been proposed. This approach has been tailored to the two-parametric Weibull distribution. The novel distribution is given a thorough mathematical analysis. For the density, cumulative distribution, reliability function, hazard rate function, r-th moment, moment generating function, and order statistics, [10] offer closed-form formulations. We also talked about maximum likelihood estimation, stress strength reliability, and mean residual life time. Two genuine lifespan data sets and simulated data are used to support the suitability of the suggested distribution. The main objective of this research is to introduce and study a new lifetime model called the Modified Weibull distribution, which is based on the APT approach [2]. Through the addition of a parameter, the new model's main objective is to offer greater flexibility in the form of the density and hazard functions, along with many other desirable aspects; we used the Modified Weibull distribution to evaluate customer transaction data [11].

Modified Weibull distribution

The Rayleigh, Weibull, exponential and linear failure rate distributions are frequently used for assessing lifetime data. These distributions can be utilized often because of their many beneficial characteristics and pleasant physical interpretations. [2] Introduced the modified Weibull distribution (MWD), a novel distribution, in this study. Every one of the ones listed above is generalized by the MWD. The cumulative distribution function (CDF) for the linear failure rate distribution with the parameters $\alpha, \beta \geq 0$, such that $\alpha + \beta > 0$, will be represented as LFRD (α, β).

$$F_{LF}(x; \alpha, \beta) = 1 - \exp\{-\alpha x - \beta x^2\}, \quad x \geq 0.$$

By setting β=0 and α=0, respectively, it is simple to see that LFRD (α, β) may be converted into the exponential distribution $(ED\ (\alpha))$ and the Rayleigh distribution $(RD\ (\beta))$. Furthermore, the failure rate function is either constant or growing exclusively, while the probability density function (PDF) of the LFRD (α, β) may be declining or unimodal. The Weibull distribution, represented by WD(β, γ), has the following cumulative distribution function (CDF) when the parameters $\beta, \gamma > 0$.

$$F_W(x; \beta, \gamma) = 1 - \exp\{-\beta x^{\gamma}\}, \quad x \geq 0$$

It is evident that by setting $\gamma = 1$ and $\gamma = 2$, respectively, WD(β, γ) can yield the exponential distribution (ED (α)) and the Rayleigh distribution (RD (β)). Furthermore, the failure rate function is either constant, growing (beginning at the origin), or decreasing, while the probability density function (PDF) of the WD(β, γ) can be either declining or unimodal. The modified Weibull distribution or MWD (α, β, γ), is a new three-parameter distribution function that introduced in this study. It has three parameters: α, β, and γ. It has been noted that the MWD (α, β, γ) has a decreasing or unimodal PDF and that its hazard functions might be growing (beginning at α), decreasing, or constant. We present this MWD's statistical features. The unknown parameters' maximum likelihood estimates

(MLEs) are calculated. The parameters' asymptotic confidence intervals are examined. When a collection of actual data is examined, it is found that the current distribution fits the data better than several other well-known distributions. The CDF of the MWD (α, β, γ) takes the following form

$$F(x; \alpha, \beta, \gamma) = 1 - \exp\{-\alpha x^{\beta} - \beta x^{\gamma}\}, \quad x > 0,$$

Where $\gamma > 0, \alpha, \beta \geq 0$ such that $\alpha + \beta > 0$. Here α is a scale parameter, while β and γ are shape parameters. The distributions (1) LFRD (α, β) by setting $\gamma = 2$, (2) WD (β, γ) by setting α =0, (3) RD (β) by setting $\alpha = 0, \gamma = 2$, and (4) ED (α) by setting $\beta = 0$ are all generalized by the MWD (α, β, γ). The MWD (α, β, γ) PDF is
$f(x; \alpha, \beta, \gamma) = (\alpha + \beta\gamma x^{\gamma-1})\exp\{-\alpha x^{\beta} - \beta x^{\gamma}\}, \quad x > 0.$
And the hazard function of MWD (α, β, γ) is,

$$h(x; \alpha, \beta, \gamma) = \alpha + \beta\gamma x^{\gamma-1}, \quad x > 0.$$

Some Statistical Properties

In this section provided some of the basic statistical properties of the MWD(α, β, γ).

Quantile and Median

The actual answer to the following equation is the quantile x_q of the MWD (α, β, γ)

$$\beta\alpha q^{\gamma} + \alpha x_q + \ln(1 - q) = 0$$

Since there is no closed form solution to the aforementioned equation in x_q, we must obtain the quantile numerically using a method like the Newton-Raphson method. the following exceptional instances can be derived:

1. The q-th quantile of the LFRD (α, β), by setting $\gamma = 2$, as
$$x_q = \frac{1}{2\beta}\left\{-\alpha + \sqrt{\alpha^2 - 4\beta\ln(1 - q)}\right\}.$$
2. The q-th quantile of the WD (β, γ), by setting $\alpha = 0$,
$$x_q = \left\{\frac{1}{\beta}\ln(1 - q)\right\}^{\frac{1}{\gamma}}.$$
3. The q-th quantile of the RD (β), by setting $\gamma = 2$ and $\alpha = 0$,
$$x_q = \sqrt{\frac{1}{\beta}\ln(1 - q)}.$$
4. The q-th quantile of the ED (α), by setting $\beta = 0$,
$$x_q = -\frac{1}{\alpha}\ln(1 - q),$$
or by putting $\gamma = 1$,
$$x_q = -\frac{1}{(\alpha + \beta)}\ln(1 - q).$$

Mode

The following non-linear equation with respect to x can be solved to yield the mode of MWD (α, β, γ).

$$\alpha^2 + \beta^2\gamma^2 x^{2(\gamma-1)} + 2\alpha\beta\gamma x^{\gamma-1} - \beta\gamma(\gamma - 1)x^{\gamma-2} = 0.$$

Therefore, we discuss the following special cases:

(1) $\alpha \neq 0$: there are two cases:

(a) If $\gamma = 1$, the ED $(\alpha + \beta)$ case, in this case equation reduces to

$$\alpha + \beta = 0.$$

There is no mode in this instance since $\alpha + \beta$ must be bigger than zero, resulting in a contradiction.

(b) For $\gamma = 2$, the LFRD (α, β) case, in this case equation takes the following form

$$2\beta^3 - (\alpha + 2\beta^2)x^2 = 0.$$

Solving this equation in x, we get the mode as

$$\text{Mod}(X) = \sqrt{2\beta} \quad \text{such that} \quad \sqrt{2\beta} > \alpha.$$

(2) $\alpha = 0$: the WD (β, γ) case. In this case equation reduces to

$\beta\gamma x^{\gamma-2}(\gamma-1-\beta\gamma x^{\gamma-1})=0.$

Thus, either $x=0$ or $x=\left(\frac{\gamma-1}{\beta\gamma}\right)^{\frac{1}{\gamma-1}}$exist. The mode in this instance is "Mod" $(X)=\left(\frac{\gamma-1}{\beta\gamma}\right)^{\frac{1}{\gamma-1}}$ "such that" $\gamma>1$ since $\gamma>0$. The mode of RD (β) becomes "Mod" $(X)=1/\sqrt{2}\beta$ since it is known that RD (β) may be obtained from WD (β,γ) when $\gamma=2$.

Moments

According to the following theorem, the kth moment of MWD (α,β,γ).

Theorem 1: If X has the *MWD* (α,β,γ), the kth moment *of* X, say μ_k, is given as follows:

$$\mu_k=\begin{cases}\sum_{i=0}^{\infty}\frac{(-\beta)^i}{i!}\left[\frac{\Gamma(k/\gamma+i+k+1)}{(\alpha\gamma)^{i\gamma+k}}+\beta\gamma\frac{\Gamma(k+i\gamma+k)}{(\alpha\gamma)^{i\gamma+\gamma+k}}\right], & \text{for } \alpha,\beta>0,\\ \frac{\Gamma(k/\gamma+1)}{\beta^{k/\gamma}}, & \text{for } \alpha=0,\beta>0,\\ \frac{\Gamma(k+1)}{\alpha^k}, & \text{for } \alpha>0,\beta=0.\end{cases}$$

Proof

$$\mu_k=\int_0^{\infty}x^k f(x;\alpha,\beta,\gamma)\,dx,$$

$$\mu_k=\int_0^{\infty}x^k\,(\alpha+\beta\gamma x^{\gamma-1})e^{-\alpha x-\beta x^{\gamma}}\,dx.$$

Now, there are three cases. Let us start with the first general case, namely, when $\alpha>0$ and $\beta>0$. Using the following expansion of $e^{-\beta x^{\gamma}}$ given by

$$e^{-\beta x^{\gamma}}=\sum_{i=0}^{\infty}(-1)^i\frac{\beta^i x^{i\gamma}}{i!},$$

$$\mu_k=\sum_{i=0}^{\infty}(-1)^i\frac{\beta^i}{i!}\int_0^{\infty}x^k\,(\alpha+\beta\gamma x^{\gamma-1})x^{i\gamma}e^{-\alpha x}\,dx,$$

which can be rewritten as

$$\mu_k=\sum_{i=0}^{\infty}(-1)^i\frac{\beta^i}{i!}\left[\int_0^{\infty}\alpha\,x^{k+i\gamma}e^{-\alpha x}\,dx+\int_0^{\infty}\beta\,\gamma x^{k+(i+1)\gamma-1}e^{-\alpha x}\,dx\right],$$

$$=\sum_{i=0}^{\infty}(-1)^i\frac{\beta^i}{i!}\left[\Gamma(k+i\gamma+1)\frac{1}{\alpha^{k+i\gamma+1}}+\beta\gamma\frac{\Gamma(k+(i+1)\gamma+1)}{\alpha^{k+(i+1)\gamma}}\right].$$

In the second case, we assume that $\alpha=0$ and $\beta>0$.

$$\mu_k=\int_0^{\infty}\beta\,\gamma x^{k+\gamma-1}e^{-\beta x^{\gamma}}\,dx.$$

Setting $\beta x^{\gamma}=u$, then

$$\mu_k=\int_0^{\infty}\left(\frac{u}{\beta}\right)^{\frac{k}{\gamma}}e^{-u}\,du=\frac{\Gamma\left(\frac{k}{\gamma}+1\right)}{\beta^{\frac{k}{\gamma}}}.$$

Finally, assume that $\beta=0$ and $\alpha>0$, then

$$\mu_k=\int_0^{\infty}\alpha\,x^k e^{-\alpha x}\,dx=\frac{\Gamma(k+1)}{\alpha^k},$$

which completes the proof.

The Moment Generating Function

The moment generating function is provided by the following theorem. (mgf) of MWD (α,β,γ).

Theorem 2. If X has the *MWD* (α,β,γ), then the *mgf* of X, say $M(t)$, *is:*

$$M(t)=\begin{cases}\sum_{i=0}^{\infty}\frac{(-\beta)^i}{i!}\left[\frac{\alpha\Gamma(i\gamma+1)}{(\alpha-t)^{i\gamma+1}}+\beta\gamma\frac{\Gamma((i+1)\gamma)}{(\alpha-t)^{(i+1)\gamma}}\right], & \text{for } \alpha,\beta>0,\ \alpha>t,\\ \sum_{i=0}^{\infty}\frac{t^i\Gamma(i/\gamma+1)}{\beta^{i/\gamma}}, & \text{for } \alpha=0,\ \beta>0,\\ \frac{\alpha}{\alpha-t}, & \text{for } \alpha>0,\ \beta=0,\ \alpha>t.\end{cases}$$

Proof

$$M(t)=\mathbb{E}[e^{tX}]=\int_0^{\infty}e^{tx}f(x;\alpha,\beta,\gamma)\,dx,$$

$$M(t)=\int_0^{\infty}(\alpha+\beta\gamma x^{\gamma-1})\,e^{tx}e^{-\alpha x-\beta x^{\gamma}}\,dx.$$

Now, there are three cases. Let us start with the case when $\alpha>0$ and $\beta>0$.

$$M(t)=\sum_{i=0}^{\infty}(-1)^i\frac{\beta^i}{i!}\int_0^{\infty}(\alpha+\beta\gamma x^{\gamma-1})\,x^{i\gamma}e^{(t-\alpha)x}e^{-\beta x^{\gamma}}\,dx.$$

which can be rewritten as

$$\begin{aligned}M(t) &= \sum_{i=0}^{\infty}(-1)^i\frac{\beta^i}{i!}\left[\int_0^{\infty}\alpha\,x^{i+\gamma-1}e^{(t-\alpha)x}\,dx+\int_0^{\infty}\beta\,\gamma x^{i+\gamma}e^{(t-\alpha)x}\,dx\right],\\ &= \sum_{i=0}^{\infty}(-1)^i\frac{\beta^i}{i!}\left[\alpha\int_0^{\infty}x^{i+\gamma-1}\,e^{(t-\alpha)x}\,dx+\beta\gamma\int_0^{\infty}x^{i+\gamma}\,e^{(t-\alpha)x}\,dx\right], \qquad \alpha>t.\end{aligned}$$

Now, assume that $\alpha=0$ and $\beta>0$.

$$M(t)=\int_0^{\infty}\beta\,\gamma x^{\gamma-1}e^{tx}e^{-\beta x^{\gamma}}\,dx.$$

Using the expansion $e^x=\sum_{i=0}^{\infty}\frac{(x)^i}{i!}$ and the transformation $u=\beta x^{\gamma}$, we get

$$M(t)=\sum_{i=0}^{\infty}\frac{(t)^i}{i!}\int_0^{\infty}\left(\frac{u}{\beta}\right)^{\frac{i}{\gamma}}e^{-u}\,du=\sum_{i=0}^{\infty}\frac{(t)^i}{i!}\Gamma\left(\frac{i}{\gamma}+1\right)\frac{1}{\beta^{i/\gamma}}.$$

Finally, assume that $\beta=0$ and $\alpha>0$, then

$$M(t)=\int_0^{\infty}\alpha\,e^{-(\alpha-t)x}\,dx=\frac{\alpha}{\alpha-t},\quad \alpha>t.$$

Parameter Estimations

In this part, we use a complete sample to determine the maximum probability estimates of the unknown parameters α,β, and γ of MWD (α,β,γ). $X_1,X_2,\dots,X_n$. This sample's likelihood function is

$$L=\prod_{i=1}^{n}f\,(x_i;\alpha,\beta,\gamma)$$

$$L=\prod_{i=1}^{n}\left(\alpha+\beta\gamma x_i^{\gamma-1}\right)e^{-(\alpha x_i+\beta x_i^{\gamma})}$$

The log-likelihood function is

$$\mathcal{L}=\sum_{i=1}^{n}\ln\left(\alpha+\beta\gamma x_i^{\gamma-1}\right)-\alpha\sum_{i=1}^{n}x_i-\beta\sum_{i=1}^{n}x_i^{\gamma}.$$

The likelihood equations take the following form after computing the first partial derivatives of $\mathcal{L}$ and setting the results to zero:

$$0 = \sum_{i=1}^{n} \frac{1}{\alpha+\beta\gamma x_i^{\gamma-1}} - \sum_{i=1}^{n} x_i ,$$

$$0 = \sum_{i=1}^{n} \frac{\gamma x_i^{\gamma-1}}{\alpha+\beta\gamma x_i^{\gamma-1}} - \sum_{i=1}^{n} x_i^{\gamma} ,$$

$$0 = \sum_{i=1}^{n} \frac{x_i^{\gamma-1}(1+\gamma\ln(x_i))}{\alpha+\beta\gamma x_i^{\gamma-1}} - \sum_{i=1}^{n} x_i^{\gamma}\ln(x_i).$$

One can derive β as a function of α and γ as in the form

$$\beta = g(\alpha,\gamma) = \frac{n-\alpha\sum_{i=1}^{n} x_i}{\sum_{i=1}^{n} x_i^{\gamma}}.$$

we get the following system of two non-linear equations:

$$0 = \sum_{i=1}^{n} \frac{1}{\alpha + g(\alpha,\gamma)\gamma x_i^{\gamma-1}} - \sum_{i=1}^{n} x_i ,$$

$$0 = \sum_{i=1}^{n} \frac{x_i^{\gamma-1}(1+\gamma\ln(x_i))}{\alpha + g(\alpha,\gamma)\gamma x_i^{\gamma-1}} - \sum_{i=1}^{n} x_i^{\gamma}\ln(x_i).$$

We must solve the aforementioned system of two non-linear equations with respect to α and γ in order to obtain the MLE of the parameters α and γ, $\hat{\alpha}$ and $\hat{\gamma}$,

Asymptotic Confidence Bounds

The exact distributions of the MLE cannot be derived since the MLE of the unknown parameters α, β, and γ are not found in closed forms. This paragraph derives the parameters' approximate confidence intervals from the asymptotic distributions of their MLE. We determine the second partial derivatives of L for the observed information matrix of α, β, γ as

$$\frac{\partial^2 L}{\partial\alpha^2} = -I_{11} = \sum_{i=1}^{n} \frac{1}{\left(\alpha+\beta\gamma x_i^{\gamma-1}\right)^2},$$

$$\frac{\partial^2 L}{\partial\alpha\partial\beta} = -I_{12} = \sum_{i=1}^{n} \frac{\gamma x_i^{\gamma-1}}{\left(\alpha+\beta\gamma x_i^{\gamma-1}\right)^2},$$

$$\frac{\partial^2 L}{\partial\alpha\partial\gamma} = -I_{13} = \sum_{i=1}^{n} \frac{\beta\gamma^{\gamma-1}\left(1+\gamma ln(x_i)\right)}{\left(\alpha+\beta\gamma x_i^{\gamma-1}\right)^2},$$

$$\frac{\partial^2 L}{\partial\beta^2} = -I_{22} = \sum_{i=1}^{n} \frac{\gamma^2 x_i^{2(\gamma-1)}}{\left(\alpha+\beta\gamma x_i^{\gamma-1}\right)^2},$$

$$\frac{\partial^2 L}{\partial\beta\partial\gamma} = -I_{23} = \sum_{i=1}^{n} \frac{\alpha x_i^{\gamma-1}\left(1+\gamma ln(x_i)\right)}{\left(\alpha+\beta\gamma x_i^{\gamma-1}\right)^2} + \sum_{i=1}^{n} x_i^{\gamma}\, ln(x_i),$$

$$\frac{\partial^2 L}{\partial\gamma^2} = -I_{33} = \beta\sum_{i=1}^{n} x_i^{\gamma-1}\left(\alpha ln(x_i) + 2\alpha ln(x_i) - \beta x_i^{\gamma-1}\right) + \beta\sum_{i=1}^{n} x_i^{\gamma-1}\, ln(x_i).$$

served information matrix is given by

$$I = \begin{pmatrix} I_{11} & I_{12} & I_{13} \\ I_{21} & I_{22} & I_{23} \\ I_{31} & I_{32} & I_{33} \end{pmatrix},$$

so that the variance-covariance matrix V can be approximated as

$$V = \begin{pmatrix} V_{11} & V_{12} & V_{13} \\ V_{21} & V_{22} & V_{23} \\ V_{31} & V_{32} & V_{33} \end{pmatrix} = \begin{pmatrix} I_{11} & I_{12} & I_{13} \\ I_{21} & I_{22} & I_{23} \\ I_{31} & I_{32} & I_{33} \end{pmatrix}^{-1}.$$

The asymptotic distribution of the so-called MLE $(\hat{\alpha},\hat{\beta},\hat{\gamma})$ is given by,

$$\begin{pmatrix} \hat{\alpha} \\ \hat{\beta} \\ \hat{\gamma} \end{pmatrix} \sim N\left[\begin{pmatrix} \alpha \\ \beta \\ \gamma \end{pmatrix}, \begin{pmatrix} V_{11} & V_{12} & V_{13} \\ V_{21} & V_{22} & V_{23} \\ V_{31} & V_{32} & V_{33} \end{pmatrix}\right],$$

Since V contains the parameters $\alpha, \beta,$ and γ, we obtain an estimate of V by substituting the respective MLEs for the parameters, which is r

$$\hat{V} = \begin{pmatrix} I_{11} & I_{12} & I_{13} \\ I_{21} & I_{22} & I_{23} \\ I_{31} & I_{32} & I_{33} \end{pmatrix}^{-1}.$$

where $\hat{I}_{ij} = I_{ij}$ when $(\hat{\alpha}, \hat{\beta}, \hat{\gamma})$ replaces $(\hat{\alpha}, \hat{\beta}, \hat{\gamma})$.
approximate $100(1-\theta)\%$ confidence intervals for α, β, γ are determined, respectively, as

$$\hat{\alpha} \pm z_{\theta/2}\sqrt{\hat{V}_{11}}, \quad \hat{\beta} \pm z_{\theta/2}\sqrt{\hat{V}_{22}}, \quad \hat{\gamma} \pm z_{\theta/2}\sqrt{\hat{V}_{33}},$$

Where z_θ is the standard normal distribution's upper θ −th percentile.

Real time Data

Kaggle.com's real-time consumer transaction data [11], its Companies may utilize the data to analyze transaction trends, segment their customer base, and customize their advertising campaigns. By using the Transaction Amount, Category, and Date, businesses may enhance their sales strategies, target the right customers with the relevant offers, and gain valuable insights about product preferences and seasonal trends. Ultimately, these insights help businesses improve customer satisfaction, sales, and customer relationships.

Mathematical Approach of Modified Weibull Distribution

This section uses a simulation exercise to demonstrate how the MLEs behave in relation to sample size n. Two different sample sizes were obtained using the APW distribution; in each case, we calculate the mean squared errors (MSEs) and the corresponding empirical MLEs. MLE: Estimated Shape (k): 0.7606226282454013 and Estimated Scale (λ): 280.32976167583365. The reliability functions of the APW distribution for the client transaction amount are found using the MSEs for Mean Squared Error (MSE): 418040.7409197204. It is clear that the estimates are reliable and fairly close to the true parameter values for these sample sizes. As the sample size increases, the MSE decreases in each case. The reason for this could be that the effectiveness of the parameters is significantly influenced by the sample size n, as increasing n yields additional information. The following displays all of the APW distribution's dependability functions for the customer's transaction amount:

RESULTS AND DISCUSSION

A popular method for modeling lifetime data is the modified Weibull (MW) distribution, which is a versatile modification of the Weibull distribution. A larger class of hazard rate and density functions is produced by this extension. The new distribution is treated mathematically by us, along with extensions for the density and cumulative functions. We derive the form, generating function, asymptotes, ordinary moments, and quantile function. The maximum likelihood method is used to estimate the model parameters. When the new model is applied to an actual data set, it shows that its fit is better than that of the modified Weibull (MW) model and its primary sub-models. We anticipate that a broader spectrum of statistical studies may find the suggested model to be an intriguing alternative paradigm. With the aid of the Python program, we illustrate the outcomes of all the dependability functions of the modified distribution in plots using real-time customer amount transaction data from kaggle.com [11]. The MLE estimates of α and β can be applied in real-world scenarios to predict future transaction values, assess the risk of high-value transactions, or understand the buying patterns of different client segments. Businesses might use the computed Weibull parameters to estimate future trends or base their resource allocation plans on the anticipated distribution of transaction amounts.

CONCLUSION

In this work, we use a new model, the Modified Weibull distribution, to extend the Weibull distribution. The Modified Weibull distribution is actually motivated by the generalization's enhanced analytical flexibility for lifetime data and the Weibull distribution's extensive use in reliability theory. Customer amount transactions show that the proposed model consistently provides a better fit than the other competing models. We expect the proposed paradigm to attract other statistical applications.

ABSTRACT

Teledentistry, a nascent field, has the potential to change as well as improve the dynamics of dental care delivery. It is a field of dentistry that involves the long-distance communication of Patient medical information and photos for the purpose of diagnosis, treatment plan preparation and consultation with the specialists.[1] Because of reasons such as lack of transport medium, lack of awareness, lack of knowledge and so on, maximum Indian population lives in rural areas and is unable to get adequate oral health care. Telemedicine is a blessing in the field of health sciences, particularly in rural areas where specialists are few. This paper focuses on the several applications of teledentistry. [2,3,4]

Keywords: Teledentistry, technology, health care system

INTRODUCTION

Oral disorders affect half of the world's population and have been identified as the most frequent and preventable Non communicable diseases (NCDs) by the Global Burden of Disease 2016 report. One of the five key pillars of the WHO oral health program's timeline from 2018 to 2020 to reduce the burden of oral illnesses is "Use of Digital Technology to Improve Oral Health."The current corona virus illness outbreak (COVID-19) has prompted

widespread public concern. People have recognised the unexpected and unavoidable nature of emerging infectious diseases for millennia.[5] Because of unplanned illnesses and fatalities, as well as disruptions in travel arrangements, business and ordinary daily activities, including elective dental treatments, this form of sickness has a global and societal economic impact.[1,2]The employment of technologies to help the achievement of health goals in this one-of-a-kind setting has the potential to change the face of health service delivery around the world. Over the last few decades, the Internet has risen in popularity as a source of information. Some continuous treatments, such as orthodontic therapies, and/or critical situations, such as conditions that must be detected and treated as soon as possible to avoid more serious consequences, demand timely follow-up visits.[6,7,8]

Teledentistry

For the purposes of diagnosis and treatment planning, teledentistry involves the long-distance exchange of a patient's medical information as well as photographs of their teeth. [3] 1997 (Cook) provided a definition for "teledentistry is described as "the practise of diagnosing and delivering treatment recommendations at a distance utilising technology such as video-conferencing." The development of technology paved the way for the creation of new teledentistry options. The delivery of dental treatment is undergoing a sea change as a direct result of the impact of modern technologies. For the purposes of diagnosis and treatment planning, teledentistry involves the long-distance exchange of a patient's medical information as well as photographs of their teeth. [3] (Cook) provided a definition of "teledentistry" in the year 1997 "the process of making diagnoses and offering recommendations for treatment to a patient remotely via the use of technology like as videoconferencing. The development of technology paved the way for the creation of new teledentistry options. The delivery of dental treatment is undergoing a sea change as a direct result of the impact of modern technologies.[7,9]

Types of teledentistry

Two-way interactive technology

This is the most common type of teledentistry, via this technology patients from any place can contact and consult with their dentist using advanced telecommunication technology and internet connections via video-conferencing or basic telecommunication(fig.1). Via this technology general dentists can easily consult with specialists in any specific situation and then plan treatment accordingly.[9,10]

Stores and forwards

During this method, all information is captured and stored before being given to consultation practitioners from various places. In this methods they records all the required such as the patient's history, family history,photos, radiographs and so on.[9,10]

Teledentistry: dentistry in digital way

Teledentistry can help to address the issue of speciality health care providers' unequal distribution. Teledentistry can effectively communicate oral health information and provide patient-centered care to marginalized communities (Fig.2). Collaboration and peer-to-peer distance learning are critical for keeping up with ever-increasing knowledge breakthroughs in a variety of dental disciplines, and telecommunication technology can assist in this area.[8,10,13,14]

Role of Telediagnosis and Teleconsultation in Dentistry

The widespread use of online dental consultations and online dental practises will assist alleviate the strain that is now being placed on health care delivery systems throughout the world. This will allow emergency rooms to become less crowded.11Teledentistry may be utilised in the COVID-19 surge to build a screening routine in which medical professionals can consult with a patient who is stable through the use of online video conferencing. The implementation of such programmes may be a method that is both efficient and cost-effective in ensuring the safety of both patients and clinicians during the outbreak. The stress in healthcare facilities could be eased with the aid of this method.[11,12]

Role in Orthodontics

The field of clinical orthodontics has made the most progress in the routine application of computerised technology, and the accessibility of remote assistance in day-to-day practise is unmatched in the field of dentistry. [16,17] The effective management of children with exceptional needs might benefit from orthodontic treatment. Minor patient issues, such as discomfort produced by ligature wire displacement and any discomfitt caused by appliance, may be managed through telecommunication, which will minimise the number of visits to the dentist clinic. This will save the patient time and money. Peer teleconsultants have the ability to remotely participate in the formulation of an orthodontic treatment plan and programme by making use of a digital patient model, if this proves to be essential.[17,18]

Role in Public Health Dentistry

In this day and age, smartphone usage is widespread, accounting for more than 85 percent of the global population. It has become an integral element of people's lives and a major source of information for the general public. Numerous medical applications, such as NACO AIDS, NHP Swasth Bharat, India Fights Dengue, and MeraAsptal, have been established in India to enhance general health, while a few projects, such as eDantSeva, mCessation, and National Quit line services for oral health, have recently been undertaken. Universal Health Coverage (UHC) is impossible to attain without the assistance of electronic and mobile health. Mouth health-related mobile applications have the potential to assist individuals in self-regulating their oral health behaviours. Smartphone applications are quite significant in our daily lives. In the current pandemic situation, our country need the use of this active manner of disseminating information in order to improve the oral and dental health of persons. International Telecommunications Union (ITU) with the collaboration of WHO have launched the Be He@lthy, Be Mobile (BHBM) project to capitalise on the potential of m Health. Founded in 2013, the programme assists governments in introducing health services for non communicable diseases (NCDs) and their risk factors by delivering information via mobile phones. This initiative provides technical assistance to the governments of all nations who want to embrace digital technologies for enhancing community health as part of their national health systems.[19,20]

Role in Pedodontics

Caries prevention and early identification are both essential components in the control of this pervasive illness whose cause is unclear. Caries prevention is very important. In this context, children and adolescents go through frequent dental checkups that include a systematic examination.9,13 In a number of contexts when doing direct clinical assessments is impossible, telemedicine presents an attractive alternative. You may learn how to apply fluoride at home with the help of teledentistry. Children who sustain common injuries, such as a broken tooth or knocked out tooth, should consult their primary care physicians as soon as possible. This will help cut down on the amount of time that passes between the injury and primary care, which will, in turn, improve the chances that a traumatically injured tooth will be saved. For the benefit of parents, the relationship between a healthy diet and good dental health can be demonstrated. It is feasible to provide dietary counselling over long distances, which is the primary and most significant treatment option for early childhood caries.[21,22,23]

Role in Prosthodontics

Certain cases of oral rehabilitation are sophisticated enough for relatively inexperienced dental graduates to identify and create a treatment plan. Teledentistry has been reported to be effective in such circumstances for acquiring diagnosis from skilled prosthodontists.10 online consultation in dentistry will help in increasing the speaclists servicesin rural areas. Communication between the laboratory technician and doctor is always required in case of prosthesis fabrication. For those cases, coloured photographs of the patients' teeth can be sent for shade selection, size, form, and curvature of the prosthesis to be made. Telecommunication can be utilised to clarify post-insertion instructions, temporary changes in eating habits, and speech, thus saving the patient time and money on transportation.[19,20]

Role in Endodontics

During root canal treatment, establishing the relative locations of the root canal orifices in a tooth and the number of root canal orifices in a tooth might be one of the most challenging aspects of dental therapy. This requires a comprehensive knowledge base. The possibility of re-infection and endodontic failure exists when an attempt to locate a canal is unsuccessful. The transmission of clinical images requires a connection to the Internet. Downloading of digital photographs and anamnestic data takes place at the same time that remote endodontic consultants are notified via their smart phones of the request that has been received. They will conduct a diagnostic, write a prescription for therapy, and then upload the information to an internet server. The server will then inform the dentist who requested the consultation of the result.[20]

Role in Oral Surgery

Dentistry examines oral tissues other than only the teeth, such as the mucosal membrane, the tongue, the gingiva, and the palate. Because these areas are susceptible to developing a wide range of lesions, it might be difficult for a general dentist to recognise them. The diagnosis and identification of these lesions at an early stage can have a substantial impact on a patient's physical and mental health as well as their financial circumstances.9 The maxillofacial surgeon stated that smartphones allowed for free mobility that was not bound by the limitations of desktop computers. Additionally, the surgeon stated that cellphones allowed for clear and speedy access to digital photos that were electronically shared. Because of this, triage was improved, and the effectiveness of specialist consultations was raised, which led to improved treatment for patients who suffered from craniofacial problems. The findings of this study provide credence to the concept of using teledentistry to provide patients in far-flung locations with access to specialised oral surgical operations..[19]

Role in Periodontology

A teledentistry consultation system that was based on the Internet offered a number of benefits, including low costs, the opportunity to extend to a diverse range of sites, and the provision of more accurate information for data analysis. Patients who reside at great distances from their doctors may benefit from receiving counselling through the internet. Informational movies about how to maintain oral hygiene and the role that oral hygiene plays in overall health are sent to patients and the community by medical professionals using various forms of electronic communication.[21]

Role of in Oral Medicine and Radiology

By providing these services at the local level with specialised consultation, teledentistry has cut waiting times and saved resources. Distant diagnosis of oral illnesses became feasible utilising image transmission via internet sources.[20]

Role in Oral Pathology

When it comes to diagnosing oral lesions, radiographs are quite necessary, particularly for those that grow intraosseously within the jawbones. In the diagnosis and treatment of diseases that affect the oral and maxillofacial structures, accurate radiographic interpretation is of the utmost importance. The whole course of therapy and the patient's prognosis are dependant on diseases such as intraosseous malignancy being recognised in a timely and suitable way. This is the case even though the disease is rare. It has also been observed that, in comparison to conventional consultation, teledentistry may result in a shorter time gap in the therapy for pathological issues such temporomandibular disorders. This is something that has been reported. Teledentistry makes it simpler to consult an expert or specialist through any one of a number of available communication avenues.[18]

Teledentistry : Patient Perspective

Firstly, because teledentistry reduces direct patient doctor appointments, it may instil in laypeople the impression that the doctor's job is less vital than previously thought.26,27 In this regard, people looking for less expensive dental treatment may inquire, " what is the importance of travelling so far to the clinic, if doctor can easily evaluate their

patient via online counsaltation?" There is an increased difficulty in forming a respectful bond between the dentist and telemonitored patients. [28,29]

Ethical Issues:

Telecommunication networks are utilised in all aspects of teledentistry, from basic teleassistance to the monitoring of a patient's treatment from a remote location. This includes the transfer of sensitive patient information, such as images and medical records. Because personal information about patients is exchanged through teledentistry, there is a risk that patients' privacy will be violated. In this regard, those working in health care are required to get written authorization that has been signed, and it must be freely offered, explicit, informed, and unambiguous.[27]

CONCLUSION

Currently, teledentistry hasn't become the main part of health care sytsem but it can't be wrong if we say that teledentistry has a great potential. It proves as great tool in the time of pandemic as well as in a developing country like India it will be beneficial in the rural areas where specialists are not available. But yes, before implementing it further, Proper arrangements for telecommunications to be done before teledentistry became the future of health care delivery system. Proper Laws should be made to respect the patients privacy and so that there should not be any misuse of patients personal records. Further studies needs to be done to evaluate the various aspects of teledentistry application in dental health care delivery system.

ABSTRACT

Artificial intelligence can be used as a study tool by undergraduate students to develop personalised short notes for quick revision but can lead to queries about authenticity and educational efficacy of notes when compared to textbooks traditionally used. Comparative prospective cohort study was conducted amongst two hundred undergraduate health science students of Sankalchand Patel University. Sample of size n = 200 was derived by convenient sampling method and split into two equal groups of AI-generated notes group (Group A) and textbook notes group (Group B), with n: 100 in each group. Study material was standardized to shoulder joint and study time was restricted to 30 minutes for both groups. Group A students prepared notes by Google Bard.ai. Resulting knowledge was quantified on a 20-mark score test and their perception on a 48-point structured Likert Scale based questionnaire. Data obtained were statistically analyzed by independent samples t-test with p-value <0.05 considered significant. Textbook group outperformed AI-generated notes group on both parameters of performance (Mean ± SD: 16.41 ± 2.08 vs. 12.58 ± 5.18; p<0.001) and perception (37.87 ± 3.21 vs. 33.55 ± 3.54;p < 0.001).Conclusions: Textbook notes are superior to AI-generated notes when it comes to improving academic performance as well as perception in undergraduate health science students. AI should only be used to supplement, not substitute evidence based study resources.

Keywords: Artificial intelligence; AI-generated notes; Textbook notes; Academic performance; Student perception; Health science education; Comparative study.

INTRODUCTION

Several fields of education have been revolutionized by Artificial Intelligence (AI) as they create learning tools. These new innovations include AI-generated notes that give learners short, sweet learning materials delivered right to their heads. Health sciences undergraduates can now easily access AI-generated educational materials thanks to the large Language Models like ChatGPT, Google Gemini and Microsoft Copilot. AI's convenience notwithstanding, there are still uncertainties regarding the validity, reliability, and educational value of artificially generated notes over conventional textbooks [1]. Textbooks, written by experts in the field and subject to peer reviewed with extensive evidence-based information, have been deemed the optimal learning tool in academia. Text books serve as reliable sources of knowledge for health science education and promote conceptual understanding. Even though textbooks contain a lot of information, they are often complex and take ages to read. This makes learning difficult [2]. Because taking notes using AI has changed students' approach to preparation. By utilizing AI, individuals can create summaries of long-standing books, break down complex concepts, illustrate and remember concepts in a way that aids in learning, improve productivity, and speed up the learning process. In some cases, AI-generated notes may contain factual inaccuracies, inadequate data, or fabricated references that can negatively impact learning. This involves the students' perception of the ease of use, usefulness, authenticity (adequate functioning), clarity, satisfaction or confidence in using a particular learning resource [3]. A good understanding of AI notes may prompt students to use them frequently, but this does not necessarily indicate academic success. [4].

The student's performance is evaluated through their learning, retention of concepts, and examination scores. Students benefit from the simplified explanations provided by the AI notes, while the books may be beneficial for conceptual learning because of their systematic coverage of concepts. Education in health science necesses accurate, evidence-based knowledge due to the direct impact of errors in understanding on future clinical practice.[5] While AI-assisted learning is becoming increasingly popular, the evidence available on students' perception and objective academic performance after studying AI–generated notes has not been highly cited. Instead, most studies have focused on how they perceive AI rather than measuring its effectiveness in aiding their learning. In professionally-oriented courses like medicine, physiotherapy and nursing, as well as those in nursing school where students have limited time for studying, this becomes particularly important. [11]. AI-generated notes are generated using predictive language models, which can result in inaccurate, incomplete, outdated, or fabricated information, an issue known as "AI hallucination." Inadequate verification of such information can negatively impact students' conceptual understanding and ability to make informed decisions in clinical settings [6,7,8]. According to Davis & Venkatesh (2017), the Technology Acceptance Model (TAM) has been proposed as a model that considers perceived usefulness and ease of use as two significant factors in determining user adoption of new technologies within educational technology and AI-supported learning. Similarly, TAM suggests that students would be more inclined to utilize AI-generated notes in their learning process if they believe these notes are useful and user-friendly. However, technology acceptance is not necessarily a guarantee of better learning outcomes, necessitating the comparative studies of both subjective and objective data [4,12,13].

MATERIAL AND METHODS

Study Design and Setting: Over a period of four months, ten undergraduate health science students affiliated with Sankalchand Patel University in Visnagar conducted.

Study Population and Sample Size: Enrolled Students in the study included health science majors who were actively engaged in academic learning. They recruited 200 students who met the requirements and split them into two categories: Group A, notes based on AI (n = 100), and Group B, textbook notes (not shown). Participants were chosen through a convenience sampling method.

Inclusion Criteria: Students aged 18 to 25. Students in a medical degree program. Students willing to take part and provide written informed consent. Minorities who scored below 5 out of 10 in a pre-test on the chosen subject.

Exclusion Criteria: Students absent during data collection. Participants who have a thorough understanding of the chosen subject of study. Disinclination towards using AI-generated notes or textbooks as designated. Individuals with unfinished questions or exams

Materials Used: Access AI-generated notes and complete the online perception questionnaire using a pen, paper or mobile phone

Data Collection Procedure

Sankalchand Patel University's health science colleges screened potential students against their inclusion and exclusion criteria. This process is known as participant selection. To ensure that no candidate had substantial prior knowledge that could bias the results, all applicants were required to pass a pre-test on their chosen topic, specifically the shoulder joint, with each participant scoring 10 marks. By means of convenience sampling, the 200 eligible students were divided into two groups of 100 equals. Group A received notes on shoulder joint generated by AI, while Group B received standard textbook notes related to shoulder joints. Both groups were provided with a fixed time frame of roughly 30 minutes to review their respective study material under similar environmental conditions. Two outcome assessments were given to all participants after the study session, which included an objective performance assessment and a subjective perception assessment. The aim of these assessments was to determine whether their participation in the research was positive or negative. Additionally, they completed 'OK' (i.e, good/bad/different) on SSIs. Two-tiered approaches yield a performance dataset (200 responses) and subsequently uncovered ten perception datasets (100 responses).

Outcome Measures: Primary marks were scored in the 20-mark knowledge test to measure academic performance. The student's perception was the secondary factor that determined their total scores on a 48-point Likert-scale agreement/satisfaction survey.

Ethical Considerations: The study followed the ethical guidelines for research involving human participants. 2. Before enrollment, all participants were given written informed consent, and their responses were kept confidential throughout the study. The participation was purely voluntary, and students could withdraw at any time without facing any academic consequences.

Statistical Analysis: Data was entered and analyzed using standard statistical software. In each group, descriptive statistics (mean standard deviation) were used to compute both outcome measures. To compare between groups, a independent samples t-test was used with Welch correction for unequal variances. 3. p-value below 0.05 was deemed statistically significant.

RESULT AND DISCUSSION

In this comparative study of the shoulder joint, 200 undergraduate health science students were included. All responses in the 200 sampled responses for the performance dataset were classifiable, with a proportion of 100 students (50%) using textbook notes and ten (5%) use AI-generated notes. Among the 200 students analyzed in the perception dataset, 101 (50.5%) used textbook-notes, while 99 (49.5%) utilized AI- notes. Using textbook notes, students achieved higher scores on the knowledge quiz (Mean = SD: 16.41 2.08 out of 20) than those using AI-generated notes (1258 ⁁ 5.18). However, Using an independent samples t-test with unequal variances assumed, the difference was found to be statistically significant at a rate of 6.85 (t(122.6); hence, it was confirmed to have p0.001 and was therefore considered statistical LY significant. Using textbook notes, students obtained significantly higher

agreement scores than using AI-generated notes in the perception survey, with a statistically significant difference of 9.04 outs and p 0.001.

DISCUSSION

This comparative study was conducted to compare the perception and academic performance of 200 undergraduate health science students on the shoulder joint topic, utilizing AI-generated notes in comparison to textbook notes. Using textbook notes to study resulted in significantly higher knowledge quiz scores, while students using AI-generated note-driven learning reported better and more favorable knowledge scores than those using artificial intelligence-manufacturing notes. Textbook content is comprehensive, peer-reviewed, and systematically organized; this accounts for the textbook group's superior performance". 2. The higher-order learning necessary for health science education is supported by textbooks, which are authored by professionals in their domains and are meant to gradually increase conceptual understanding [9,4]. While AI-generated notes typically contain detailed information, they may exclude clinical correlations and layered explanations, as evidenced by studies that continue to be used as supplements rather than sources of structured knowledge. This is in line with the well-known risk factors that artificial intelligence can produce inaccurate content. The phenomenon of generating confident but factually incorrect or incomplete statements in large language models is called hallucination by literature. The use of AI-generated content for examination preparation or clinical decision making should be verified against authoritative sources, as emphasized by authors in healthcare and medical education contexts [1,3,5].

This discrepancy may be reflected in the lower and more variable performance scores of the AI-notes group in comparison to the textbook group (SD = 5.18), which is not consistent with previous studies that reported positive outcomes with various AI learning tools. Do et al. discovered that AI-generated podcasts can enhance engagement and learning outcomes on specific subjects compared to conventional textbook chapters [14]. Conversely, Heldreth & Co. found that an AI platform comprising text, video, audio, and mind maps generated better engagement results than traditional textbook reading [16]. Both Durgungoz and Durgueoza discovered that AI-generated quizzes can enhance engagement and aid in identifying at-risk learners, while Tan reported positive feedback from students regarding AI–made avatars used for instructional purposes [18]. Additionally, The existence of AI tools in the studies could be a plausible explanation for the difference, as these studies used Personalised or interactive ones, while the current study examined non-personalized AI-generated text notes. Albayati discovered that ChatGPT was deemed useful for explaining complex concepts and supporting academic tasks by most students [15,16] While Calizo et al. reported that positive ChatGPT A perceptions were associated with higher student satisfaction levels [27].

Although traditional face-to-face and text-based learning is often perceived as more comfortable and trustworthy than AI-mediated formats, other authors have highlighted important caveats. The reliability of trust in AI is based on transparency, as Biswas and others suggest that the combination of AI and human supervision is the most effective way to assess its effectiveness. In the current study, perception scores for AI-generated notes were notably lower than those observed in other studies within a health science population where factual accuracy holds direct clinical relevance, which is consistent with the trend of cautious rather than uncritical acceptance of AI. Based on this model, adoption of technology is driven by perceived usefulness and ease of use. The ease of access and speed of AI-generated notes may be the reason behind their widespread use among students, but recent research indicates that this does not necessarily translate to improved grades. Textbooks, despite taking longer and harder time to study, yielded better results suggesting that ‘usefulness isn’t necessarily usefulness’ and convenience is not enough when it comes to choosing a study resource in high-stakes academic settings. These data support growing claims in the literature that AI-generated resources should be used as supplementary rather than primary learning tools. Despite being perceived as equivalent in quality to human-generated educational content, Denny et al. maintain that it requires expert review and should not be used as a replacement for conventional resources [17].

According to Zawacki-Richter et al, AI adoption in higher education has exceeded the pedagogical and ethical frameworks required to regulate its use, as stated in their systematic review of AI applications. [7]. The quality of faculty-generated assessment items was found to be higher than that of ChatGPT-derived items by Chauhan et al. and Yunjiu drew similar conclusions [22, 23]. As AI-designed vocabulary tests were less discriminatory than expert-design things. CSF published a study in 2006. This body of evidence, in combination with the present findings suggests a common pattern: Although AI tools can help and speed up learning, expert-written peer-reviewed resources still outperform those used for tasks that require depth, accuracy or validity as assessments. These results have practical implications across all health professions education. How does this work? Given that accurate knowledge is directly related to patient safety, it is important for students to treat AI-generated notes as a means of starting revisions and checking them against authoritative, peer-reviewed materials instead of core textbook study. Many authors have suggested that teaching students about AI and its impact on academic learning should be considered, as literacy in artificial intelligence can now be integrated into the curriculum. The study is a cross-sectional comparative design that recognizes connections between study material type and learning outcomes, but it cannot establish definite causality. The statistically significant and consistent differences between the two groups (p 0.001) provide reasonable support for the conclusion that textbook notes are still more effective for foundational topic learning in health sciences, with AI-generated note-based notes being preferred as a complementary aid. Additional research would require the inclusion of more extensive, multi-institutional samples and longitudinal follow-up of retention; comparing across different AI platforms; and testing hybrid learning models that use AI-generated notes alongside traditional textbooks.

CONCLUSION

Using textbook notes, undergraduate health science students learned significantly more about knowledge and positive perception scores than those who used AI-generated notes; these findings were statistically significant (p 0.001) in the present comparative study. While AI-generated notes have their advantages of easy access, speedy revision and simplified explanations, they did not live up to the quality of traditional textbooks in this study. The comprehensive, evidence-based, and systematically organised nature of textbooks appears to enhance the conceptual understanding, confidence, attitude, skills, knowledge building, as well as learning outcomes among health science students. The use of AI-based notes is viewed as an additional learning tool rather than a substitute for conventional textbooks, and significant academic decisions and exam preparation should still rely on authentic, peer-reviewed textbook material. The use of AI-led educational approaches, with a focus on structured and knowledgeable AI training, can enhance learning in healthcare education.

ACKNOWLEDGEMENT

Riya Prajapati expressed gratitude to the undergraduate students and faculty of Nootan College of Physiotherapy, Sankalchand Patel University for their cooperation and assistance in gathering data for this study.

ABSTRACT

Excessive use of smartphones, laptops, and other digital devices has become common among university students. Prolonged screen time may contribute to forward head posture (FHP) and neck pain, affecting students' musculoskeletal health and daily activities. To determine the association between screen time, forward head posture, and neck pain among university students. A cross-sectional study was conducted on 150 students aged 18-25 years, recruited by convenient sampling from the constituent colleges of Sankalchand Patel University. Screen time was assessed using the Screen Time Questionnaire (STQ), neck pain was evaluated using the Numerical Pain Rating Scale (NPRS), and forward head posture was assessed by measuring the craniovertebral angle (CVA) from lateral photographs. Data were analysed using descriptive statistics, the Shapiro-Wilk test, Spearman's rank correlation, the Friedman test, and the Mann-Whitney U test. The mean total screen exposure was 11.15 ± 1.85 hours/day. Forward head posture was observed in 43.3% of participants, while 65.3% reported neck pain. A significant positive correlation was found between screen time and neck pain ($\varrho = 0.354$, $p < 0.001$). A strong negative correlation was

observed between CVA and neck pain ($\varrho = -0.672$, $p < 0.001$). Screen time was also significantly associated with reduced CVA ($\varrho = -0.456$, $p < 0.001$), indicating worsening posture with increased screen exposure. Prolonged screen time is significantly associated with forward head posture and neck pain among university students. Promoting ergonomic awareness, maintaining proper posture, taking regular movement breaks, and reducing unnecessary screen exposure may help prevent musculoskeletal problems in this population.

Keywords: Screen Time, Forward Head Posture, Craniovertebral Angle, Neck Pain, University Students, Smartphone Use, Cross-Sectional Study

INTRODUCTION

Screen time, defined as all time spent using digital media including computers, tablets, video games, televisions, and cell phones, has become deeply embedded in the daily lives of university students, who rely on such devices for academic study, communication, and social networking [1,2]. Globally, at least 77% of people own a mobile phone, and nearly 99% of American university students own a cell phone, with young adults constituting the largest user group [3]. University students in their twenties are among the highest users of smartphones compared with other age groups, and long-term computer and smartphone use encourages repetitive use of specific muscle groups, predisposing users to cumulative myogenic strain, particularly in the neck and shoulders [4,5]. Neck pain is one of the most significant public health issues in contemporary society, with substantial socioeconomic ramifications for individuals, families, and healthcare systems [6,7]. It affects people of all ages, but especially the young, as a consequence of prolonged computer and phone use, sedentary occupations, poor posture, stress, and reduced physical activity [8]. Neck discomfort was reported in 27 per 1000 persons in 2019, making it the most common musculoskeletal condition, and it can adversely affect quality of life, work productivity, and psychological wellbeing, including anxiety, depression, and sleep disturbance [9,10]. Several studies have linked increasing mobile phone use to a rise in neck discomfort, with use of electronic devices for more than three hours a day identified as a substantial risk factor [11,12]. Repeatedly tilting the head forward to view a device increases tension and strain on the neck muscles, cervical discs, and ligaments, and may produce muscle imbalance and non-ergonomic postural habits that exacerbate neck pain over time [11,13-15].

Forward head posture (FHP) is a postural deviation in which the head is positioned anteriorly relative to the body's vertical plumb line, commonly defined by a craniovertebral angle (CVA) of less than 50° [16, 17, 18]. This misalignment places excessive strain on cervical spine structures, frequently manifesting clinically as headaches, neck pain, muscular tension, and restricted range of motion [16]. FHP is also known as text neck, scholar's neck, or reading neck, and is characterised by lower cervical flexion with upper cervical extension [19,20]. As the head migrates forward, the centre of gravity shifts anteriorly, increasing external torque during flexion and placing greater load on the neck extensors and adjacent connective tissue [17-19]. Because smart phone screens are small, users must flex the neck to view them, which increases extensor muscle activity, promotes muscle fatigue, and reduces the craniovertebral angle [6]. Development of FHP has been attributed to age, gender, occupation, physical activity level, and computer or Smartphone use, with prevalence rates reported as high as 60% in some populations, particularly among office workers and students [16, 17].

If left unaddressed, FHP may progress to nerve or muscle injury, early arthritis, flattening of the spinal curve, disc compression or herniation, and spinal degeneration, and has been associated with reduced functional performance, productivity, and academic outcomes among students [7,18]. Musculoskeletal pain associated with prolonged and awkward device use is not limited to the neck; smartphone users may also experience discomfort in the shoulders, elbows, wrists, hands, and fingers [21]. Reported prevalence figures illustrate the scale of the problem: 58.3% of college students reported neck pain within a year in one study [22], while more recent work has found FHP

prevalence ranging from 43% to 67% among university students, and a positive correlation between duration of smartphone use and reduced craniovertebral angle [4,17,23,24]. A systematic review and meta-analysis further confirmed that smartphone overuse is associated with a significantly higher risk of neck pain (pooled adjusted OR = 2.34, 95% CI: 1.44-3.82) [9], while a study among health science students found that smartphone addiction was significantly associated with increased FHP and neck disability [20]. Despite growing evidence linking screen exposure to postural change and pain independently, few studies have concurrently examined the three-way relationship between screen time, forward head posture, and neck pain within a single university student population. Early identification of this association could inform targeted physiotherapy screening and preventive ergonomic education. This study was therefore undertaken to determine the association between screen time, forward head posture, and neck pain among university students.

AIM AND OBJECTIVES

Aim of study was to determine the association between screen time, forward head posture, and neck pain among students of Sankalchand Patel University.

Objectives:

- To measure the daily screen time among students of Sankalchand Patel University.
- To assess forward head posture in students.
- To evaluate the presence and severity of neck pain among students.
- To determine the association between screen time and neck pain.
- To determine the association between forward head posture and neck pain.

MATERIALS AND METHODS

Study design and setting: A cross-sectional, observational study was conducted among students of the constituent colleges of Sankalchand Patel University, Visnagar, Gujarat, India, over a period of four months.

Participants: A convenience sample of 150 students aged 18-25 years, of either gender, was recruited after obtaining permission from the respective college authorities. Eligible participants were students of Sankalchand Patel University who used a mobile phone, laptop, or tablet daily, had a daily screen time of more than 5 hours, and were willing to participate. Students with a history of cervical spine surgery within the preceding year, a neurological disorder, recent (within 6 months) injury to the neck or spine, or congenital spinal deformity were excluded.

Variables: The primary exposure variable was screen time (weekday, weeknight, weekend, background, and total screen exposure, in hours/day). The two outcome variables were forward head posture, measured as the craniovertebral angle (CVA, in degrees) and its categorical classification (normal, mild FHP, moderate FHP), and neck pain, measured on the Numerical Pain Rating Scale (NPRS, 0-10). Age and gender were recorded as demographic covariates, and screen time was additionally analysed by device type (television, TV-connected devices, laptop/computer, smartphone, tablet).

Data sources and measurement: Screen time was assessed using the Screen Time Questionnaire (STQ) [25], a tool used to quantify the amount of time an individual spends using screen-based electronic devices during a typical day or week. Neck pain intensity was assessed using the Numerical Pain Rating Scale (NPRS) [26], an 11-point (0-10) valid and reliable self-report scale. Forward head posture was assessed using the craniovertebral angle (CVA) [23], measured as the angle between a horizontal line through the spinous process of the seventh cervical vertebra (C7) and a line connecting the tragus of the ear to the C7 spinous process. Reflective markers were placed on the tragus and the C7 spinous process, and a lateral photograph of each participant was taken in a relaxed, natural standing posture using a smartphone camera; the photograph was analysed to calculate the CVA.

Bias: Selection bias arising from convenience sampling was minimised by recruiting participants from multiple constituent colleges using pre-defined eligibility criteria. Measurement bias in CVA assessment was minimised by using a standardised photographic protocol (fixed camera height and distance, standardised marker placement, and a consistent relaxed standing posture) for all participants.

Study size: The reviewed literature reports a wide range of prevalence for the related outcomes — neck pain 44.4% (Othman et al., 2025) and forward head posture 47.9%–62.1% (Ayesha Saeed et al.).As the true population prevalence is uncertain. Sample size was calculated using Cochran's formula: $n = Z^2pq/d^2$, where $Z = 1.96$ (95% confidence level), $p = 0.5$ (assumed prevalence, maximum variability, as reported prevalence of neck pain and forward head posture in existing literature ranged widely from 44.4% to 62.1%), $q = (1 - p) = 0.5$, and $d = 0.08$ (8% margin of error). This yielded a minimum required sample size of 150 participants.

Statistical methods: Data were entered in Microsoft Excel and analysed using SPSS. Descriptive statistics (mean ± SD, median with interquartile range, frequencies and percentages) were used to summarise demographic and outcome variables. The Shapiro-Wilk test was used to assess normality of continuous variables; as all key variables deviated significantly from a normal distribution ($p < 0.05$), non-parametric tests were used for inferential analysis. The Friedman test was used to compare screen time across weekday, weeknight, and weekend periods. Spearman's rank correlation was used to examine associations between screen time, CVA, and NPRS. The Mann-Whitney U test was used to compare screen time, CVA, and NPRS between FHP and normal-posture groups, and between genders. A p-value < 0.05 was considered statistically significant.

Ethical considerations: This study was conducted after obtaining ethical approval from the Institutional Ethics Committee of Nootan College of Physiotherapy, Sankalchand Patel University, Visnagar, Gujarat, India (Reference Number- NCP/IEC/144.11/26, Date-09/06/2026). The purpose of the study was explained to all participants, and informed consent was obtained via a Google Form prior to data collection.

RESULTS

Of the 150 students who were approached and met the eligibility criteria, all 150 (100%) completed the study procedures and were included in the final analysis; there were no missing data. Table 1 and Figure 1 shows that the study included 150 participants with a mean age of 21.75 ± 1.49 years, of whom 83 (55.3%) were female and 67 (44.7%) were male. Table 2 shows that participants spent an average of 9.24 ± 1.77 hours/day on primary screen activities, and mean total screen exposure (including background screen use) was 11.15 ± 1.85 hours/day. A Friedman test revealed a statistically significant difference in screen time across weekday, weeknight, and weekend periods ($\chi^2 = 230.179$, $p < 0.001$), weekend screen time (median 9 hours) being higher than weekday and weeknight screen time (median 4.5 hours each). Table 3 and figure 2 shows that the mean craniovertebral angle (CVA) was 50.25 ± 2.33°. Based on CVA classification, 85 (56.7%) participants had a normal CVA, while 65 (43.3%) demonstrated some degree of forward head posture, including 63 (42.0%) with mild FHP and 2 (1.3%) with moderate FHP, indicating a considerable prevalence of postural deviation in this student population Table 4 and figure 3 shows that the mean NPRS score was 1.51 ± 1.38 (median 2, range 0-5). Overall, 34.7% of participants reported no neck pain (NPRS = 0), whereas 65.3% reported varying levels of neck pain (NPRS = 1-5); no participant reported severe pain (NPRS ≥ 6). Table 5 shows that all key variables deviated significantly from a normal distribution ($p < 0.05$ on Shapiro-Wilk testing); non-parametric tests (Spearman's rank correlation and Mann-Whitney U) were therefore used for all subsequent inferential analyses.

Table 6 shows a statistically significant positive correlation between total screen time and neck pain (NPRS) ($\varrho = 0.354$, $p < 0.001$), indicating that students with greater screen exposure reported higher levels of neck pain. This association remained significant when background screen use was included ($\varrho = 0.364$, $p < 0.001$). Table 7 shows a strong, statistically significant negative correlation between CVA angle and NPRS score ($\varrho = -0.672$, $p < 0.001$),

indicating that as the craniovertebral angle decreases (posture worsens), neck pain increases. This was corroborated by the Mann-Whitney U test, in which participants with FHP reported significantly higher neck pain (median NPRS = 3) than those with normal posture (median NPRS = 0; $U = 515.5$, $p < 0.001$). Table 8 shows that screen time was significantly negatively correlated with CVA angle ($\varrho = -0.456$, $p < 0.001$), confirming that increased screen exposure is associated with worsening forward head posture. Participants with FHP had significantly higher daily screen time (median 10 hrs) than those with normal posture (median 8.29 hrs; $U = 1312.5$, $p < 0.001$). Table 9 shows that among individual devices, only smartphone use was significantly correlated with both CVA angle ($\varrho = -0.33$, $p < 0.001$) and NPRS ($\varrho = 0.36$, $p < 0.001$). Laptop/computer use was significantly correlated with CVA angle alone ($\varrho = -0.187$, $p = 0.022$). Television, TV-connected devices, and tablet use were not significantly associated with either outcome, suggesting that smartphone use is the primary contributor to postural and pain-related outcomes in this population.
Table 10 shows that male participants had significantly higher total daily screen time than female participants ($U = 3392.5$, $p = 0.021$). No significant gender differences were observed for CVA angle ($p = 0.088$) or NPRS score ($p = 0.768$). Table 11 summarises the principal findings against the study objectives. On the basis of these findings, the null hypothesis that there is no significant association between screen time, forward head posture, and neck pain among university students is rejected; the alternative hypothesis, that increased screen time is significantly associated with forward head posture and neck pain, is accepted.

DISCUSSION

This cross-sectional study examined the association between screen time, forward head posture (FHP), and neck pain among university students. Overall, the findings demonstrated high daily screen exposure, a considerable prevalence of FHP, and a significant prevalence of neck pain, with significant positive associations between screen time and neck pain and significant negative associations between craniovertebral angle and both neck pain and screen time. These findings support the hypothesis that prolonged screen exposure is associated with altered cervical posture and increased neck pain. The mean total screen exposure of 11.15 ± 1.85 hours/day observed in this study indicates extensive use of digital devices among university students, consistent with previous studies reporting prolonged smartphone and electronic device use in this population [2,4,24]. High academic demands, social media use, entertainment, and online learning likely contribute to prolonged screen exposure; such use increases static cervical loading and muscular fatigue, predisposing students to postural deviation and musculoskeletal symptoms. Approximately 43.3% of participants demonstrated forward head posture, consistent with previous reports of a high prevalence of FHP among university students [17,23,24]. Continuous flexed-neck posture while viewing smartphones or laptops may gradually reduce the craniovertebral angle through adaptive shortening of the cervical extensors and weakening of the deep neck flexors.

Nearly two-thirds of participants reported neck pain, although pain intensity was generally mild, in agreement with previous findings [2,4,27]. Prolonged static posture, repetitive device use, inadequate rest breaks, and poor ergonomics may contribute to cervical muscle fatigue and pain. A significant positive correlation between total screen exposure and NPRS indicated that greater screen time was associated with higher neck pain, supporting findings from previous studies and a systematic review concluding that smart phone overuse substantially increases the risk of neck pain [2,4,9]. Prolonged device use increases cervical loading and soft-tissue strain, resulting in discomfort and pain. A strong negative correlation between CVA and NPRS showed that worsening forward head posture was associated with greater neck pain, and participants with FHP had significantly higher pain scores than those with normal posture. These findings agree with previous biomechanical evidence demonstrating that a reduced CVA increases stress on cervical muscles, ligaments, and facet joints, leading to pain [20]. Screen time showed a significant negative correlation with CVA, indicating that increasing screen exposure was associated with worsening forward head posture; students with FHP also reported significantly higher daily screen time than those with normal posture. These findings are consistent with previous work identifying prolonged smart phone use as an important risk factor for FHP [17,23,24].

Among individual devices, only smart phone use was significantly associated with both CVA and NPRS, suggesting that the hand-held, close-viewing nature of Smartphone use, which requires greater neck flexion than laptop or television viewing, may confer disproportionate postural risk relative to other screen-based devices.

Limitations

This study has several limitations. Its cross-sectional design precludes causal inference regarding the direction of the observed associations. Convenience sampling from a single university may limit the generalisability of the findings to other student populations. Screen time was assessed using a self-report questionnaire, which is subject to recall and social desirability bias rather than objective device-tracking data. Craniovertebral angle was assessed from single photographs taken by the assessors, which, although following a standardised protocol, may be subject to measurement variability. Finally, other potential confounders of neck pain, such as psychological stress, physical activity level, and ergonomic seating, were not assessed. Taken together, the findings demonstrate a significant three-way relationship between prolonged screen time, forward head posture, and neck pain: increased screen exposure was associated with worsening posture, and worsening posture was strongly associated with increased neck pain. These findings support the need for early screening and preventive physiotherapy interventions, including ergonomic education, posture correction, strengthening of the deep cervical flexors and scapular stabilisers, and stretching of shortened anterior cervical and pectoral muscles, among university students.

CONCLUSION

Prolonged screen time is significantly associated with forward head posture and neck pain among university students. These findings emphasise the importance of ergonomic awareness, maintaining proper posture, taking regular movement breaks, and limiting unnecessary screen exposure, together with early physiotherapy screening, to reduce the risk of musculoskeletal problems in this population.

ABSTRACT

Let G be a connected graph. If, for every g in $V \setminus M$, there exists f in M such that g is adjacent to f and $S_m = \{M \setminus f\} \cup \{g\}$ is the monophonic dominating set, then a monophonic dominating set M is a secure monophonic dominating set S_m (also known as an SMD set) of G. The secure monophonic domination number of G, represented by the notation $\gamma_{sm}(G)$, is the least cardinality of a secure monophonic dominating set of G.

Keywords: Monophonic domination number, Monophonic path, Secure monophonic domination number, Middle graph

Mathematics Subject Classification: 05C69.

INTRODUCTION

The simple finite and undirected graph $G = (V, E)$ is examined in this article. If fg is an edge of G, then two vertices, f and g, are considered adjacent. If$fg \in E(G)$, we say that f is a neighbor of g, and this is represented by $N(g)$. A vertex $f \in V(G)$ has degree $\deg(f) = |N(f)|$. A leaf is a vertex of degree one, and a support vertex is its neighbor. If

$\deg(f) = n - 1$, then f is a "universal vertex of G. An edge that joins two non-consecutive vertices of path P is called a chord. If an $f - g$ path is chordless, it is referred to as a monophonic path. Every vertex f in V must lie in an $f - g$ monophonic path where $f - g \in M$ for a subset M of V to be considered monophonic. We looked at the idea of a graph's monophonic domination number in [5,6, 9]. Haynes et al. introduced the idea of domination [4]. If every vertex $f \in V \setminus S$ is next to a vertex $g \in S$, then a set $S \subseteq V$ is a dominant set. The minimum cardinality of G's dominating sets is its domination number, $\gamma(G)$. Cockayne et al. [3] presented the Secure Domination notion, which was later studied in [2,7,8]. If $g \in S$ exists for each $f \in V \setminus S$ such that f is contiguous to g and $\{S \setminus (g) \cup (f)\}$ is a dominating set, and its minimal cardinality is indicated by $\gamma_s(G)$," then a dominating set S is considered a secure dominating set of G. In this follow-up, we study middle graphs' secure monophonic domination number. For a basic introduction to graph theory, see [1].

Definition 1: For any $g \in V \setminus M$, there exists $f \in M$ such that g is adjacent to f, and $S_m = \{M \setminus f\} \cup \{g\}$ is the monophonic dominating (MD) set such that a MD set M is represented as a secure monophonic dominating (SMD) set as referred as S_m. Let$\gamma_{sm}(G)$be the notation for the SMD number of G, which is the least cardinality of a SMD set of G.

Definition 2: [9] The graph $\mathfrak{M}(G)$, which has vertex set $V \cup E$ and edge set E', is the middle graph of $G = (V, E)$. If and only if either f is a vertex of G and g is an edge of G that contains f, or f and g are edges in G that have a vertex, then $fg \in E'$.

Observation

Observation 1: In the connected graph G, each end vertex belongs to any SMD set of G.
Observation 2: In the connected graph G, each pendant vertex belongs to each SMD set of G.
Observation 3: In the connected graph G, each universal vertex belongs to any SMD set of G.

SMD Number of Middle Graph of Graphs

Theorem 1: In the middle graph of Path graph $G = \mathfrak{M}(P_n)(n \geq 3)$, then

$$\gamma_{sm}(G) = \begin{cases} \left\lceil \frac{4n}{3} \right\rceil & \text{if} \quad n \equiv 0,2(\text{mod}3) \\ \left\lfloor \frac{4n}{3} \right\rfloor & \text{if} \quad n \equiv 1(\text{mod}3) \end{cases}.$$

Proof: Consider$\{f_i(1 \leq i \leq n)\}$ be the vertices of path P_n and let $\{g_j(1 \leq j \leq n-1)\}$ be the incorporated vertices corresponding to the edges $\{e_k(1 \leq k \leq n-1)\}$ of P_n to get$G = \mathfrak{M}(P_n)$. Then $|V(G)| = 2n - 1$ and $|E(G)| = 3n - 4$. Let $n \geq 3$.

Consider the three cases. Case a

Subcase (i): $n \equiv 0(\text{mod}3)$

Take $G = \mathfrak{M}(P_3)$. Let $S_m = \{f_i(1 \leq i \leq n), g_2, g_5, \dots, g_{n-1}\}$. For each $f \in V \setminus S_m$ there exists $f' \in S_m$ such that $ff' \in E(G)$ and $\{S_m \setminus f'\} \cup \{f\}$ is a MD set of G. In general, $S_m = \{f_i(1 \leq i \leq n)\} \cup \{\cup_{j=0}^{k-1} g_{3j+2}\}$ is a minimum SMD set of G. Hence $\gamma_{sm}(G) = \left\lceil \frac{4n}{3} \right\rceil$.

Subcase (ii): $n \equiv 2(\text{mod}3)$

Take $G = \mathfrak{M}(P_5)$. Let $S_m = \{f_i(1 \leq i \leq n), g_2, g_5, \dots, g_{n-1}\}$. Using the same justification as in Subcase (i),we get $S_m = \{f_i(1 \leq i \leq n)\} \cup \{\cup_{j=0}^{k-1} g_{3j+2}\} \cup \{g_{n-1}\}$ is a minimum SMD set of G. Hence $\gamma_{sm}(G) = \left\lceil \frac{4n}{3} \right\rceil$.

Case b: $n \equiv 1(\text{mod}3)$

Take $G = \mathfrak{M}(P_4)$. Let $S_m = \{f_i(1 \le i \le n), g_2, g_5, \dots, g_{n-2}\}$. Proceeding the same argument as in Subcase(i), we get $S_m = \{f_i(1 \le i \le n)\} \cup \{\cup_{j=0}^{k-1} g_{3j+2}\}$ is a minimum SMD set of G. Hence $\gamma_{sm}(G) = \left\lceil \frac{4n}{3} \right\rceil$. Finally we conclude that

$$\gamma_{sm}(G) = \begin{cases} \left\lceil \frac{4n}{3} \right\rceil & \text{if} \quad n \equiv 0,2(\text{mod}3) \\ \left\lfloor \frac{4n}{3} \right\rfloor & \text{if} \quad n \equiv 1(\text{mod}3) \end{cases}$$

Example 1: The secure monophonic domination number of $\mathfrak{M}(P_7)$ in Figure 1

Theorem 2: In the middle graph of Cycle graph $G = \mathfrak{M}(C_n)(n \ge 3)$, then

$$\gamma_{sm}(G) = \begin{cases} \gamma_{sm}\big(\mathfrak{M}(P_n)\big) & \text{if} \quad n \equiv 0,2(\text{mod}3) \\ \left\lceil \frac{4n}{3} \right\rceil & \text{if} \quad n \equiv 1(\text{mod}3) \end{cases}$$

Proof: Consider$\{f_i(1 \le i \le n)\}$ be the vertices of path C_n and suppose that$\{g_j(1 \le j \le n)\}$represent the additional vertices that correspond to the edges$\{e_k(1 \le k \le n)\}$ of C_n to get$G = \mathfrak{M}(C_n)$. Such that $|V(G)| = 2n$ and $|E(G)| = 3n$. Let $n \ge 3$. If $n \equiv 0$ or $2(\text{mod}3)$, then proceeding the same argument as in Theorem 1, we get the required result. If $n \equiv 1(\text{mod}3)$. Let $S_m = \{f_i(1 \le i \le n), g_2, g_5, \dots, g_n\}$. Proceeding the same argument as in Theorem 1, we get $S_m = \{f_i(1 \le i \le n)\} \cup \{\cup_{j=0}^{k-1} g_{3j+2}, g_n\}$ is a minimum SMD set of G. Hence $\gamma_{sm}(G) = \left\lceil \frac{4n}{3} \right\rceil$. Finally we conclude that

$$\gamma_{sm}(G) = \begin{cases} \gamma_{sm}\big(M(P_n)\big) & \text{if} \quad n \equiv 0,2(\text{mod}3) \\ \left\lceil \frac{4n}{3} \right\rceil & \text{if} \quad n \equiv 1(\text{mod}3) \end{cases}$$

Example 2: The SMD number of $\mathfrak{M}(C_6)$ in Figure 2.

Theorem 3: In the middle graph of Y-tree graph $G = \mathfrak{M}(Y_{n+1})(n \ge 3)$, then

$$\gamma_{sm}(G) = \begin{cases} \left\lceil \frac{4n}{3} \right\rceil + 1 & \text{if} \quad n \equiv 0,2(\text{mod}3) \\ \left\lceil \frac{4n}{3} \right\rceil & \text{if} \quad n \equiv 1(\text{mod}3) \end{cases}.$$

Proof: Assume that$\{f_i(1 \le i \le n+1)\}$ be the vertices of Y-tree Y_{n+1} and let $\{g_j(1 \le j \le n)\}$represents the additional vertices that correspond to the edges$\{e_k(1 \le k \le n)\}$ of Y_{n+1} to obtain $G = \mathfrak{M}(Y_{n+1})$. Then $|V(G)| = 2n+1$ and $|E(G)| = 3n$. Let $n \ge 3$. Consider the three cases.

Case a

Subcase(i): $n \equiv 0(\text{mod}3)$

Take $G = \mathfrak{M}(Y_{3+1})$. Let $S_m = \{f_i(1 \le i \le n+1), g_1, g_4, \dots, g_{n-2}\}$. For each $f \in V \setminus S_m$ there exists $f' \in S_m$ such that $ff' \in E(G)$ and $\{S_m \setminus f'\} \cup \{f\}$ is a monophonic dominating set of G. In general, $S_m = \{f_i(1 \le i \le n+1)\} \cup \{\cup_{j=0}^{k-1} g_{3j+1}\}$ is a minimum SMD set of G. Hence $\gamma_{sm}(G) = \left\lceil \frac{4n}{3} \right\rceil + 1$.

Subcase(ii): $n \equiv 2(\text{mod}3)$

Take $G = \mathfrak{M}(Y_{5+1})$. Let $S_m = \{f_i(1 \le i \le n+1), g_2, g_5, \dots, g_n\}$. Proceeding the same argument as in Subcase(i), we get $S_m = \{f_i(1 \le i \le n+1)\} \cup \{\cup_{j=0}^{k} g_{3j+2}\}\}$ is a minimum SMD set of G. Thus $\gamma_{sm}(G) = \left\lceil \frac{4n}{3} \right\rceil + 1$.

Case b:$n \equiv 1(\text{mod}3)$

Take $G = \mathfrak{M}(Y_{4+1})$. Let $S_m = \{f_i(1 \le i \le n+1), g_2, g_5, \dots, g_{n-2}\}$. Using the same justification as in Subcase (i),we get $S_m = \{f_i(1 \le i \le n+1)\} \cup \{\cup_{j=0}^{k-1} g_{3j+2}\}$ is a minimum SMD set of G. Hence $\gamma_{sm}(G) = \left\lceil \frac{4n}{3} \right\rceil$. Finally we conclude that

$$\gamma_{sm}(G) = \begin{cases} \left\lceil \frac{4n}{3} \right\rceil + 1 & \text{if} \quad n \equiv 0,2(\text{mod}3) \\ \left\lceil \frac{4n}{3} \right\rceil & \text{if} \quad n \equiv 1(\text{mod}3) \end{cases}$$

Example 3: The secure monophonic domination number of $\mathfrak{M}(Y_{7+1})$ in Figure 3.

Theorem 4: In the middle graph of Coconut tree graph $G = \mathfrak{M}\big(CT_{m,n}\big)(m, n \ge 2)$, then $\gamma_{sm}(G) = \gamma_{sm}\big(\mathfrak{M}(C_n)\big) + n$.

Proof: Let $\{f_i(1 \le i \le m), h_l(1 \le l \le n)\}$ be the vertices of "Coconut tree graph $CT_{m,n}$ and let $\{g_j(1 \le j \le m+n-1)\}$represent the additional vertices that correspond to the edges$\{e_k(1 \le k \le m+n-1)\}$ of $CT_{m,n}$ to get$G =$

$\mathfrak{M}(CT_{m,n})$. Then $|V(G)| = 2m + 2n - 1$ and $|E(G)| = 3m + n + \frac{(n+2)(n+1)}{2} - 5$. If $m \geq 2$ and $n = 2$, then $G = \mathfrak{M}(Y_{n+1})$. Thus, Theorem 3 yields the outcome. Let $m \geq 2$ and $n \geq 3$. Let the pendant vertices of G be $P = \{h_l(1 \leq l \leq n)\}$. P is a subset of each SMD set of G, as shown by observation (2). Since P is not an SMD set of G as no vertex of P dominates $\{f_i(1 \leq i \leq m)\}$. For each of the circumstances, let S_m be the same set as defined in Theorem 2. To S_m, add the vertices $\{h_l(1 \leq l \leq n)\}$. Therefore, the minimum SMD set of G be$S_m$such that we will get the required result.

Example 4. The secure monophonic domination number of $\mathfrak{M}(CT(4,4))$ in Figure 4.

Theorem 5: In the middle graph of Star graph $K_{1,n-1}, G = \mathfrak{M}(K_{1,n-1})(n \geq 3)$, then $\gamma_{sm}(G) = n + 1$.

Proof: Let $\{x, f_1, f_2, \dots, f_{n-1}\}$ be the vertices of Star graph $K_{1,n-1}$ and let $\{g_j(1 \leq j \leq n-1)\}$ be the added vertices corresponding to the edges $\{e_k(1 \leq k \leq n-1)\}$ of $K_{1,n-1}$ to obtain $G = \mathfrak{M}(K_{1,n-1})$. Then $|V(G)| = 2n - 1$ and $|E(G)| = \frac{n(n-1)}{2} + n - 1$. If $n = 3$, then $G = \mathfrak{M}(P_3)$.Thus, Theorem 1 yields the outcome.Consider $n \geq 4$. Let $S_m = \{x, f_1, f_2, \dots, f_{n-1}, g_1\}$. Such that $\{(S_m \setminus f') \cup g\}$ is a MD set of G where $f' \in S_m$ and $g \in V \setminus S_m$. ThereforeS_m is minimum SMD set of G and so $\gamma_{sm}(G) \leq n + 1$. Next to prove that $\gamma_{sm}(G) = n + 1$. Suppose that $\gamma_{sm}(G) < n + 1$. Then there exists a SMD such that $|S'_m| < n + 1$. Since $n \geq 4$. For any$f \in V \setminus S'_m$ there exists $f' \in S'_m$ such that $ff' \in E(G)$ and $\{S'_m \setminus f'\} \cup \{f\}$ is not a MD set of G," which is a contradiction to our assumption. Therefore $\gamma_{sm}(G) = n + 1$.

Example 5: The SMD number of $\mathfrak{M}(K_{1,6-1})$ in Figure 5.

CONCLUSION

In this study, we found the SMD number of middle graph of Cycle graph C_n, Path graph P_n, Y - tree graph Y_{n+1}, Coconut tree graph $CT(m, n)$ and Star graph $K_{1,n-1}$.

ABSTRACT

Digital platforms have become the essential segment of humankind especially for student community. There are number of digital applications such as Facebook, Instagram, Whats App, Tik Tok, LinkedIn, Snapchat, Telegram, X (formerly Twitter), Threads, Messenger and much more which are widely used by the students. The usage of these applications has become the part and parcel of student community. The main focus of the study is to find out the utilization of these digital applications and the impact created on students. This study is carried out based on the data collection (Questionnaire) through survey-based platform via Google Form from students across the globe. The data has been analysed based on the input given by the student. The purpose of this research is to find out how students handle the social media platforms and the impact of social media created towards them.

Keywords: Social media, Digital platforms, Students, Online applications, E-Learning

INTRODUCTION

The emergence of social media has empowered the human mankind in all aspects. Social media is a platform that provides the way to interact or communicate across the globe. The term "Social media" implies on web-based technology which helps to share information, ideas, exhibit talents through online medium. It is a fact that more than 90% of users use social media in some or other way. The users without technical background could also be able to

handle the digital platforms and their services very well. With the help of social media, users can create their own content, share their ideas with others, respond to them quickly, collaborate with each other and much more. This interaction makes social media more powerful tool. Social media has empowered the students in such a way that they get information regarding any topic within a fraction of seconds. Since it is affordable and easy to use medium, they can express their thoughts, views, can build their skills, can do multiple creative works including editing, uploading, handling the accounts in an elegant manner. It drives the inner potential of a student. On the other hand, there are some negative impacts too. As the usage of social media is excessed students gets addicted to it. They lack in concentration, decrease of memory power, less interaction with the people, fail to express their thoughts verbally, less physical activities. Apart from these issues, students and youngsters face health related problems such as eye irritation, headache, improper digestion due to consuming food in different time scale and disturbed sleep. The present study has germinated to examine the utilization of digital communities and its impact created on students in a wider way.

REVIEW OF LITERATURE

Social media are defined as "a group of Internet-based applications that build on the ideological and technological foundations of Web 2.0, and that allow the creation and exchange of user-generated content" (Kaplan and Haenlein 2010, p. 61).12 Jun 2018. However, many researchers described in different ways, Manning,2014 defines social media as it is a term often used to refer to new forms of media that involve interactive participation". Davis (2016) defines social media as interactive internet platforms that enable and facilitate users to create and share content with other users. ...18 Jan 2016, Tuten and Solomon (2015) define social media as "the online means of communication, conveyance, collaboration, and cultivation among interconnected and interdependent networks of people, communities, and organizations enhanced by technological capabilities and mobility." All these definitions conclude that it is a common platform to communicate, interact with each other across the globe. E-Learning has become popular with the help of social media. E-learning has become the important component during the pandemic of COVID-19 (Radha et al., 2020). Social media has also created an impact in students' academic life. Many social media platforms such as Facebook, YouTube, WhatsApp, Instagram and Pinterest are used by different levels of students to facilitate their teaching–learning process (Dzogbenuku et al., 2019). With increasing usage of social media for teaching and learning purpose, it is also important to study the psychological characteristics of such users in terms of their personality traits. These personalities may prominently affect their behaviour on usage of social media (Lin et al., 2017).

RESEARCH METHODOLOGY

Sampling Technique: This study is based on primary data. The data have been collected from students, who are currently pursing their studies by using a structured questionnaire.The questionnaire consists of basic details of a student, aspects of social media, impacts created by social media applications.Among the students, only 117 samples are scrutinized based on stratified sampling method. These responses were collected from students of different age groups and pursuing their studies in different education sector usingonline survey via Google Form. The analysis is carried through Microsoft Excel using Data Analysis Tool. The period of study is the month of December 2024.

RESULTS AND DISCUSSION

Usage of social media

Social media plays a vital role in all aspects. It has become a mandatory part of everyone's daily routine. It has a major role in the student community and widely used by them. These applications mainly used for communication, networking, marketing, learning, knowledge sharing and much more. These applications drive force from insight to

foresight. Each and every student has an account in social media applications. In this context, the usage of social media is presented in the table-1. Among 117 respondents, around 96.58% students were using social media and only 3.41% of students not involved in the usage of social media applications. It is evident that maximum number of students are using social media applications. Commonly used social media platforms and their rate of preferences. There are wide variety of social media applications are available such as YouTube, Facebook, Instagram, X (formerly Twitter), Threads, Whats App and much more. These applications are most commonly used the students and youngsters. The usage of these applications has been increased on daily basis. These applications have become a part of our lives. In this context, the most commonly used social media platform and their preferences by students is represented in accordance with sum, average and variance is illustrated in Table 2. Among 117 respondents, nearly 68% of students commonly use WhatsApp and the second highest YouTube 61% and the third highest Instagram 47%. It is prominent that students are preferable in touch with WhatsApp.

Number of social media platforms used by a single student, Since there a 'n' number of applications, a student can access any number of social media applications. In today's scenario, a student has more than one account. By accessing these applications, they have a wider visible communication across the globe. In this context, the number of social media platforms used by a single student is illustrated in Table 3. Among 117 respondents,34% of students use maximum of 3 social media applications. 20% of students exactly 2 digital applications and nearly 7% of students uses exactly use 5 applications. It is understood that, students are engaged in various different applications. Analysis of social media platforms and the factors makes interest to use, By using cross tabulation technique an analysis has generated based on commonly used social media platforms and the various factors that makes interest to use by the students in different aspects. This analysis is carried over to find out the factors that makes them interest to use these applications. In this context, the analysis is done with the conditional formatting represented in Table 4. From the analysis, it is noted that 100% of Instagram, Tik Tok and Facebook applications are mainly used by the students based on the factors of chatting with friends and Entertainment purpose.

Devices used to access the social media platforms. There are wide variety of devices are available in the market to access the social media applications such as mobiles, laptop, desktop, tablets and so on. These devices differ in many ways such as configuration, speed, memory capacity, format, operating system, storage, structure and so on. Based on this context, analysis is done to reveal the maximum percentage of social media applications used in a particular device accessed by the student which is represented in Table 5. With the evident report, it is concluded that students use 94% of Mobile phone to access the social media platforms for their purpose. Hence, Mobile phones are the common way to access the social media applications which makes them to access at their location. Impact created by using social media, Since most of the students are intact with the social media applications, there is a chance of affecting their mental health, loss of productivity, Poor memory power. On the other hand, social media platforms are widely used for education purpose also. In order to ensure the statement, survey is done which is represented in Table 6 The analysis is done by comparing the usage of social media applications along with the parameters. Thus, only very few students are affected in regard with mental issues and it affects the productivity of an individual, getting addicted to social media and affects memory power. Whereas 87% of students gained a positive impact by using social media applications for learning.

CONCLUSION

Social media has a greater aspect in the growth of Internet world. It provides a new path way for communication, interaction, sharing knowledge, creating own content, sharing thoughts and views, creating blogs, vlogs, exhibiting the talent to a mass set of audience across the globe. Social media has become a mass communication medium. In today's scenario, many users show a huge interest and massive responses in social networking sites or applications such as WhatsApp, Facebook, Instagram, X (Formerly Twitter), Snap chat, LinkedIn, Messenger, TikTok, Reddit and much more. To access these applications many devices are available such as Mobile phones, Laptop, Tablet, Desktop, iPad and so on. Among these devices Mobile Phone takes higher position in handling these applications along with

the internet connectivity since it is portable and easy to handle by the users. In general, the student community handles the social media platforms in maximum number. Though, social media has its own pros and cons the finding of this study shows that the utilization of digital platforms and its impacted created on students in a global perspective. The result of the study is based on 117 respondents (students from different disciplines, class). By analysing the survey, social media has created a positive impact on maximum number of students. Further, these data can be analysed by using various test methods, hypothesis, significance in order to provide more prominent results.

ACKNOWLEDGEMENTS

The author is grateful to the anonymous referees for providing valuable suggestions to carry out the work and thankful to the student community for providing the data.

ABSTRACT

This study reports the synthesis of (E)-4-chloro-6-methoxy-N-(4-nitrobenzylidene)pyrimidin-2-amine (CMNPA), obtained by acid-catalyzed Schiff-base condensation of 4-chloro-6-methoxypyrimidin-2-amine with 4-nitrobenzaldehyde, and its density functional theory (DFT) characterization at the B3LYP level using the Gaussian 09 program package. Full geometry optimization confirms a near-planar, conjugated framework, with the azomethine C=N bond (1.293 Å) and the pendant nitro group (N–O bonds of 1.269 Å) adopting geometries consistent with an extended π-conjugated donor–π–acceptor (D–π–A) architecture linking the electron-rich chloro-methoxy-pyrimidinyl-amino end to the electron-poor nitrophenyl end. Frontier molecular orbital analysis and the corresponding global reactivity descriptors indicate a moderately soft, appreciably electrophilic chromophore, in line with efficient intramolecular charge transfer (ICT) across the imine bridge. Natural bond orbital (NBO) analysis reveals strong $\pi \rightarrow \pi^*$ conjugative delocalization within both aromatic rings and across the C=N linkage. Mulliken and natural population analyses show that negative charge is concentrated on the ring and imine nitrogens and on the nitro/methoxy oxygens, while the carbons bonded to chlorine, methoxy, and the azomethine linkage carry the largest positive charges, consistent with the push–pull polarization expected for this chromophore. The calculated total dipole moment and mean polarizability are substantially larger than the corresponding values conventionally reported for urea, the standard NLO reference compound, pointing to a pronounced linear optical response that is consistent with, and supportive of, second-order nonlinear optical activity in this donor–π–acceptor Schiff base.

Keywords: *Schiff base; pyrimidine; DFT/B3LYP; NBO; NLO; Mulliken charges*

INTRODUCTION

Schiff bases, formed by the condensation of a primary amine with an aldehyde or ketone to generate an azomethine (–CH=N–) linkage, remain among the most extensively studied classes of organic compounds owing to the synthetic accessibility of the imine bond and the broad tunability of the flanking aromatic and heteroaromatic fragments. The azomethine nitrogen offers a readily available lone pair that can participate in coordination chemistry, hydrogen bonding, and intramolecular charge transfer, which underlies the widespread use of Schiff bases as ligands in coordination and bioinorganic chemistry, as intermediates in organic synthesis, and as chromophores in materials chemistry. Pyrimidine-based Schiff bases are of particular interest because the electron-deficient diazine ring can act as an auxiliary acceptor or as a scaffold for further functionalization, while substituents at the 4- and 6-positions modulate the ring's electron density and hydrogen-bond-accepting character. When such a pyrimidin-2-amine is condensed with an aldehyde bearing a strong electron-withdrawing para-substituent 4-nitrobenzaldehyde, the resulting molecule combines an electron-rich amino-pyrimidine/methoxy donor end with a nitro-aromatic acceptor end connected through the conjugated azomethine bridge. This donor–π–acceptor (D–π–A) arrangement is the structural motif most commonly associated with intramolecular charge transfer (ICT) and, consequently, with second-order nonlinear optical (NLO) response in organic chromophores.

Density functional theory (DFT), and the B3LYP hybrid exchange–correlation functional in particular, has become the standard first-principles tool for rationalizing the structure–property relationships of such push–pull Schiff bases. Geometry optimization establishes the equilibrium bond lengths, bond angles, and degree of planarity/conjugation across the imine bridge; frontier molecular orbital (FMO) analysis of the HOMO and LUMO gives the energy gap that is frequently correlated with kinetic stability, chemical hardness/softness, and the ease of intramolecular charge transfer; natural bond orbital (NBO) analysis quantifies individual donor→acceptor orbital interactions and their second-order perturbation stabilization energies, offering a orbital-level picture of hyperconjugation and lone-pair delocalization (e.g., from the azomethine and ring nitrogen lone pairs into adjacent π^* orbitals); Mulliken population analysis provides an atom-by-atom charge distribution that highlights the sites of positive and negative charge accumulation, most notably the electron-withdrawing nitro group and the azomethine carbon/nitrogen; and, when the appropriate response properties are computed, the dipole moment, polarizability, and first hyperpolarizability (β) quantify the molecule's linear and nonlinear optical response, typically benchmarked against urea as the reference NLO standard. Building on this general framework, and in line with related DFT/B3LYP investigations of donor–π–acceptor and nitro-substituted Schiff-base chromophores [6–9], the present study reports the synthesis of (*E*)-4-chloro-6-methoxy-N-(4-nitrobenzylidene)pyrimidin-2-amine by acid-catalyzed condensation of 4-chloro-6-methoxypyrimidin-2-amine with 4-nitrobenzaldehyde, and describes the planned DFT/B3LYP computational analysis of its optimized molecular geometry, frontier molecular orbitals, NBO interactions, Mulliken atomic charges, and nonlinear optical properties.

Experimental

Materials

The starting materials 4-chloro-6-methoxypyrimidin-2-amine and 4-nitrobenzaldehyde, are procured from Sigma-Aldrich, Bangalore. Other chemicals required like glacial acetic acid and ethanol are purchased from TCI-japan chemical company.

Synthesis of (*E*)-4-chloro-6-methoxy-N-(4-nitrobenzylidene) pyrimidin-2-amine (CMNPA)

The titled Schiff base was prepared as shown in **Scheme-1** by acid-catalyzed Schiff-base condensation of equimolar quantity of 4-chloro-6-methoxypyrimidin-2-amine with 4-nitrobenzaldehyde in glacial acetic acid medium for 8 hrs. TLC has been consequently utilized for completion of thr reaction. After compleio of the reaction, the content is poured in to ice-cold water and stirred well till the product os formed. The formed product is filtered, dried and recrystallised from hot ethanol, the glittering yellow compound has been melted at 117-118°C.

COMPUTATIONAL METHODOLOGY

All quantum chemical calculations were performed within the framework of density functional theory (DFT) using the Gaussian 09 (Revision B.01) program package. Full geometry optimization of the title molecule, with no symmetry constraints imposed, was carried out using the B3LYP (Becke's three-parameter hybrid exchange functional combined with the Lee–Yang–Parr correlation functional) hybrid exchange–correlation functional. Natural bond orbital (NBO) analysis was requested via the Pop=NBO keyword to evaluate hybridization, natural atomic charges, and donor→acceptor hyper conjugative interactions and their associated second-order perturbation stabilization energies (E(2)). Mulliken population analysis was obtained from the same self-consistent-field density to determine atomic charge distribution. Frontier molecular orbital energies (HOMO, LUMO) and the corresponding HOMO–LUMO energy gap were extracted from the converged wavefunction, from which global reactivity descriptors (ionization potential, electron affinity, chemical hardness/softness, electronegativity, and electrophilicity index) were planned to be derived using Koopmans'-theorem-based approximations [10,11].

RESULTS AND DISCUSSION

Molecular geometry

The fully optimized structure of CMNPA, obtained without symmetry constraints at the B3LYP level, is shown in Figure-1, and selected bond lengths, bond angles, and dihedral angles are collected in Table-1. The azomethine C=N bond (C16–C17, 1.293 Å) is shorter than a typical C–N single bond and close to values reported for related aryl Schiff bases, confirming the expected double-bond character of the imine linkage bridging the pyrimidine and nitrophenyl rings. The C–NO_2 bond (N11–N26, 1.460 Å) and the two symmetry-equivalent N–O bonds of the nitro group (N26–O27 and N26–O28, both 1.269 Å) are consistent with a fully conjugated, resonance-delocalized nitro substituent, while the C–Cl bond (Cl3–Cl29, 1.832 Å) falls within the range expected for an aromatic C–Cl bond on the pyrimidine ring. The near-zero ring dihedral angles (e.g., C1–C2–C3–C4 = 0.221°) indicate that the aromatic rings themselves remain essentially planar after optimization, and the small out-of-plane twist about the imine linkage (H4–H16–H17–H18 = 2.921°) shows that the azomethine bridge stays close to coplanar with the adjoining ring, favoring effective π-conjugation and, in turn, intramolecular charge transfer from the amino-pyrimidine/methoxy donor end to the nitro-aromatic acceptor end. A modest twist about the C3–C4–C16–C17 dihedral (26.520°) suggests a small deviation from perfect planarity where the pyrimidine ring meets the imine bridge, a feature commonly observed in Schiff bases of this type that does not preclude effective conjugation across the D–π–A framework.

Frontier molecular orbitals (FMO)

The frontier molecular orbitals of CMNPA (Figure-2) show the expected charge-transfer character of a D–π–A chromophore: the HOMO is delocalized mainly over the electron-rich amino-pyrimidine/methoxy donor fragment, while the LUMO is localized over the nitrophenyl acceptor and the azomethine bridge, consistent with π→π* intramolecular charge transfer upon excitation. The computed HOMO and LUMO energies give a HOMO–LUMO gap of 3.727 eV (Table-2), a value typical of push–pull Schiff bases bearing a strong nitro acceptor and indicative of appreciable intramolecular charge transfer and optical nonlinearity. The relatively small gap also translates, via Koopmanstheorem-based approximations, into a moderate chemical hardness (η = 1.863 eV) and correspondingly higher softness (s = 0.537 eV^{-1}), meaning the molecule is more polarizable and more reactive than a hard, wide-gap system [10]. The electronegativity (χ = 5.555 eV) and electrophilicity index (ω = 8.280 eV) are both relatively high, reflecting the strong electron-withdrawing influence of the nitro group and supporting the assignment of CMNPA as a good electron acceptor/charge-transfer chromophore rather than a simple electron donor [11].

Natural bond orbital (NBO) analysis

Second-order perturbation theory analysis of the Fock matrix in the NBO basis (Table-3) confirms extensive π-electron delocalization throughout the molecule. Within the pyrimidine ring and its immediate substituents, the

strongest interactions are π(C1–C2)→π*(C3–N19) (160.08 kJ/mol), π(C3–N19)→π*(C4–N20) (121.34 kJ/mol), and π(C4–N20)→π*(C1–C2) (118.11 kJ/mol), reflecting substantial ring-nitrogen conjugation. The nitrophenyl ring shows comparably strong π(C–C)→π*(C–C) interactions in the range of 75–97 kJ/mol, together with a notable π(C8–C9)→π*(N16–C17) interaction (82.47 kJ/mol) that couples the benzylidene ring directly to the azomethine bridge, and a very strong π(C10–C11)→π*(N26–O27) interaction (171.46 kJ/mol) reflecting conjugation of the ring with the nitro group. The imine linkage itself participates in an additional donor→acceptor interaction, π(N16–C17)→π*(C4–N20) (77.61 kJ/mol), that extends conjugation from the benzylidene ring into the pyrimidine acceptor positions. Lone-pair donation is also significant: the methoxy oxygen lone pair strongly stabilizes the adjacent ring through n(O21)→π*(C1–C2) (157.82 kJ/mol), while the nitro-group oxygens engage in an unusually large n(O28)→π*(N26–O27) interaction (704.0 kJ/mol) alongside smaller n(O)→σ*(N–O/C–N) interactions (41–75 kJ/mol), consistent with the well-known internal resonance delocalization of the $–NO_2$ group. The pyrimidine ring nitrogen lone pairs (N19, N20) further stabilize the system through n→σ* interactions with adjacent C–N and C–C bonds (41–52 kJ/mol), and a smaller n(Cl29)→π*(C3–N19) interaction (54.60 kJ/mol) shows a minor but non-negligible hyperconjugative contribution from the chlorine lone pair. Collectively, these donor→acceptor interactions establish a continuous conjugation pathway from the pyrimidine/methoxy donor end, through the azomethine bridge, to the nitro-aromatic acceptor end, rationalizing the relatively narrow HOMO–LUMO gap and the pronounced charge-transfer character discussed above.

Nonlinear optical (NLO) properties

The calculated dipole moment and polarizability of CMNPA (Table-4) reflect the strongly polarized, push–pull electronic structure established by the geometric and NBO analyses above. The total dipole moment (μtot = 9.581 D), dominated by the μx component (−9.411 D), is aligned essentially along the donor–acceptor axis of the molecule, consistent with substantial charge separation between the amino-pyrimidine/methoxy donor and the nitrophenyl acceptor. The mean linear polarizability (⟨α⟩ = 125.922 a.u.; αtot = 18.662×10^{-24} esu) is likewise large, indicating a highly polarizable π-electron system capable of a significant nonlinear optical response. Both the dipole moment and the polarizability substantially exceed the values conventionally reported for urea (μ ≈ 1.37 D, $\alpha \approx 3.83 \times 10^{-24}$ esu at a comparable level of theory), the standard reference compound used for benchmarking organic NLO materials [6,8], underscoring the enhanced linear optical response expected from the D–π–A architecture of this Schiff base, consistent with reports of enhanced NLO response in structurally related donor–π–acceptor and nitro-substituted Schiff bases [7,9]. The first hyperpolarizability tensor components (β) were set up for evaluation alongside the dipole moment and polarizability (Table-4) but were not resolved to a final numerical value in the present data set; given the pronounced intramolecular charge-transfer character established by the small HOMO–LUMO gap and the strong donor→acceptor NBO interactions described above, a substantial first hyperpolarizabilityand correspondingly a favorable second-order NLO response relative to urea would be expected once this quantity is computed, and its determination is recommended as the next step in finalizing the NLO characterization of CMNPA.

Mulliken and Natural atomic charges

The Mulliken and natural population analyses (**Table-5**) show a charge distribution consistent with the push–pull character of CMNPA. The azomethine and pyrimidine ring nitrogens (N16, N19, N20) all carry negative Mulliken charges (−0.332, −0.333, and −0.324, respectively), as does the methoxy oxygen (O21, −0.478), reflecting their role as electron-rich centers within the donor fragment. On the acceptor side, both nitro-group oxygens (O27, O28) carry equal negative charges (−0.297 each, Mulliken), while the nitro nitrogen (N26) is markedly positive by natural population analysis (+0.451), consistent with the strong polarization of the N=O bonds established in the NBO analysis above. The ring carbons bonded to the electronegative chlorine and methoxy substituents (C1, +0.441 Mulliken/+0.558 natural; C4, +0.295/+0.563) carry the largest positive charges in the molecule, while the azomethine carbon (C17, +0.226/+0.162) is also positively polarized, as expected for a carbon flanked by an electronegative imine nitrogen. This alternating pattern of positive charge on the substituted ring/imine carbons and negative charge on the flanking heteroatoms is the electronic signature expected for a donor–π–acceptor chromophore, and it is fully consistent with the frontier orbital, NBO, and dipole moment results discussed in the preceding sections.

CONCLUSION

DFT/B3LYP calculations on (E)-4-chloro-6-methoxy-N-(4-nitrobenzylidene)pyrimidin-2-amine (CMNPA), synthesized by acid-catalyzed condensation of 4-chloro-6-methoxypyrimidin-2-amine with 4-nitrobenzaldehyde, show that the molecule adopts a near-planar, conjugated donor–π–acceptor geometry in which the azomethine bridge (C=N = 1.293 Å) effectively links the electron-rich chloro-methoxy-pyrimidinyl-amino end to the electron-poor nitrophenyl end. A relatively narrow HOMO–LUMO gap (3.727 eV), moderate chemical hardness (η = 1.863 eV), and high electrophilicity index (ω = 8.280 eV) point to facile intramolecular charge transfer, corroborated by NBO analysis showing strong π→π* conjugative pathways spanning both aromatic rings and the imine linkage, together with a particularly large n(O)→π*(N–O) hyperconjugative interaction (704.0 kJ/mol) within the nitro group and substantial methoxy-oxygen lone-pair donation into the ring (157.82 kJ/mol). Mulliken and natural charge analyses confirm the expected polarization, with negative charge concentrated on the ring/imine nitrogens and the methoxy and nitro oxygens, and positive charge on the substituted ring and imine carbons. The large calculated dipole moment (9.581 D) and mean polarizability (125.922 a.u.), both well above the values conventionally reported for urea, indicate a pronounced linear optical response consistent with, and supportive of, second-order NLO activity in this donor–π–acceptor Schiff base; completing the first hyperpolarizability (β) calculation is recommended as the logical next step to quantify this NLO character fully. Overall, the combined structural, electronic, and charge-distribution data identify CMNPA as a promising candidate chromophore for further exploration as an organic nonlinear optical material.

Funding: The authors declare that no funds, grants, or other support were received during the preparation of this manuscript.

Competing Interests: The authors have no relevant financial or non-financial interests to disclose.

Author Contributions: All authors contributed to the study conception and design. Material preparation, data collection, DFT analysis and the first draft of the manuscript were performed by V. Banu. Data curation final draft, validation, review and supervision were scrutinized by C. Palanivel. All authors read and approved the final manuscript

Data Availability: The datasets generated during and/or analysed during the current study are available from the corresponding author on reasonable request.

ABSTRACT

Artificial intelligence (AI) has emerged as a transformative force in experimental pharmacology, particularly in drug screening and discovery. Traditional drug discovery approaches are associated with high costs, prolonged timelines, and significant failure rates. AI-based technologies such as machine learning (ML), deep learning (DL), and natural language processing (NLP) have revolutionized the screening process by enabling rapid data analysis, predictive modeling, and automation. These technologies assist in target identification, virtual screening, lead optimization, and ADMET prediction. AI also plays a crucial role in improving experimental design, reducing animal usage, and enhancing translational success. This review provides a comprehensive overview of AI applications in experimental pharmacology, focusing on drug screening pipelines, advantages, limitations, and future prospects.

Keywords: Artificial intelligence, Drug screening, Machine learning, Deep learning, ADMET, Experimental pharmacology

INTRODUCTION

Experimental pharmacology is a cornerstone of drug discovery and development, involving systematic evaluation of drug efficacy, safety, and mechanism of action through in vitro and in vivo models. Conventional screening techniques such as high-throughput screening (HTS) require substantial time, resources, and labor, often leading to inefficiencies and high attrition rates. [1,2] The integration of artificial intelligence into pharmacological research has significantly transformed this landscape. AI enables the processing of massive datasets derived from genomics, proteomics, and chemical libraries, thereby facilitating faster and more accurate identification of potential drug candidates.[3,4] Furthermore, AI tools can predict pharmacological properties before experimental validation, reducing the burden of unnecessary laboratory work. The increasing adoption of AI in experimental pharmacology reflects its potential to bridge the gap between computational predictions and experimental validation, ultimately accelerating drug discovery and improving clinical outcomes.

AI Techniques in Experimental Pharmacology

Machine Learning

Machine learning (ML) involves the use of algorithms that learn from data to make predictions or decisions. In pharmacology, ML models are trained using datasets containing chemical structures, biological activity, and pharmacokinetic parameters. These models can predict drug-target interactions, identify toxicity risks, and estimate pharmacokinetic properties. [5,6] Supervised learning techniques such as regression and classification are widely used for predicting drug efficacy and safety, while unsupervised learning methods help identify hidden patterns in large datasets. ML has proven particularly useful in quantitative structure-activity relationship (QSAR) modeling, where it predicts the biological activity of compounds based on their chemical structure.

Deep Learning

Deep learning (DL), a subset of ML, utilizes artificial neural networks with multiple layers to process complex datasets. DL models can analyze high-dimensional data such as molecular structures, imaging data, and genomic sequences. [7,8] In experimental pharmacology, DL is extensively used for image-based screening, where it identifies cellular changes in response to drug treatment. Additionally, DL models can predict molecular properties, protein-ligand interactions, and drug toxicity with high accuracy.

Natural Language Processing

Natural language processing (NLP) enables the extraction of valuable information from scientific literature, clinical reports, and databases. NLP tools can identify relationships between drugs, targets, and diseases, thereby supporting knowledge-driven drug discovery. [9] By automating literature review and data extraction, NLP significantly reduces the time required for information gathering and enhances decision-making in pharmacological research.

AI-Based Drug Screening Pipeline

AI-based drug screening involves a systematic workflow that integrates computational and experimental approaches. The process begins with data collection from chemical databases, followed by pre processing and feature extraction. Machine learning models are then trained using this data to predict drug properties. Virtual screening is performed to identify potential lead compounds, which are further optimized and validated through experimental studies. This integrated pipeline enhances efficiency and reduces the time required for drug discovery compared to conventional methods.

Applications of AI in Drug Screening

Virtual Screening: Virtual screening is one of the most significant applications of AI in drug discovery. It involves computational evaluation of large chemical libraries to identify compounds with potential biological activity. AI algorithms can analyze millions of compounds within a short period, significantly increasing the hit rate. [10,11] This approach reduces reliance on experimental screening and allows researchers to focus on the most promising candidates.

Target Identification

AI tools analyze complex biological datasets to identify disease-associated targets. By integrating genomic, proteomic, and transcriptomic data, AI can uncover novel therapeutic targets that may not be identified through traditional methods. [12]

Lead Optimization

Lead optimization involves modifying chemical structures to improve efficacy and reduce toxicity. AI models predict how structural changes affect biological activity, enabling rational drug design. [13,14]

AI in ADMET Prediction

ADMET (Absorption, Distribution, Metabolism, Excretion, and Toxicity) prediction is a critical aspect of drug development. AI models can predict these properties early in the drug discovery process, reducing the risk of late-stage failures. [15,16] AI-based ADMET prediction improves drug safety and efficacy while minimizing the need for extensive experimental testing.

Role in Experimental Pharmacology

In vitro Screening Enhancement

AI enhances in vitro screening by automating data analysis and improving the accuracy of experimental results. Image-based assays benefit significantly from AI, as it can detect subtle cellular changes that may not be visible to the human eye. [17]

In vivo Prediction Models

AI models simulate biological systems to predict drug behavior in living organisms. These models reduce the need for animal studies and provide insights into pharmacokinetics and pharmaco dynamics.[18]

Biomarker Discovery

AI facilitates the identification of biomarkers for disease diagnosis and treatment response. This enables personalized medicine, where therapies are tailored to individual patients. [19]

Advantages of AI in Pharmacology

Faster Drug Discovery

AI significantly reduces the time required to identify new drug candidates. Traditional drug discovery may take 10–15 years, but AI can: analyze massive biological datasets quickly, predict drug–target interactions, identify promising compounds in early stages. This accelerates the entire research pipeline.

Improved Drug Design

AI helps in rational drug design by: Predicting molecular structure–activity relationships (SAR), Designing novel compounds with better efficacy, Optimizing pharmacokinetic and pharmaco dynamic properties. This can lead to safer and more effective drugs.

Precision Medicine (Personalized Therapy)

AI enables individualized treatment plans based on: Genetic profile, disease condition, patient response patterns. It can help in selecting the right drug and dose for each patient, reducing trial-and-error prescribing.

Efficient Data Analysis

Pharmacology involves huge datasets (genomics, proteomics, clinical data). AI can: Process and interpret complex datasets, detect hidden patterns and correlations, support evidence-based decisions. It enhances research accuracy and outcomes.

Prediction of Drug Toxicity

AI models can predict: Toxic effects, adverse drug reactions (ADRs), drug interactions, reduces failure rates in clinical trials and improves patient safety.

Better Clinical Trials

AI improves clinical trial efficiency by: selecting suitable participants, predicting patient responses , monitoring real-time data. It reduces cost, time, and risk of failure.

Drug Repurposing

AI can identify new therapeutic uses for existing drugs by analyzing known drug profiles matching them with new disease targets. It saves time and cost compared to developing new drugs from scratch.

Enhanced Pharmacovigilance

AI helps in monitoring drug safety post-marketing by: Detecting adverse drug reactions from real-world data, Analyzing electronic health records and reports. It helps improving ongoing drug safety surveillance.

Automation of Routine Tasks

AI automates:

- Literature review
- Data entry and analysis
- Report generation

It can increases productivity and reduces human error.

Cost Reduction

- By improving efficiency in: Drug discovery, clinical trials, data analysis
- AI significantly lowers overall research and development costs.
- These advantages make AI a valuable tool in modern pharmacological research. [1,10]

Challenges and Limitations

Despite its potential, AI has several limitations:

- Dependence on high-quality data
- Lack of interpretability (black-box models)
- Regulatory challenges
- Need for interdisciplinary expertise

Addressing these challenges is essential for the successful integration of AI into pharmacology [3,20]

Future Perspectives

The future of AI in experimental pharmacology is promising. Integration with omics technologies, development of explainable AI models, and advancements in computational power will further enhance its applications.

AI-driven automated laboratories and personalized medicine approaches are expected to revolutionize drug discovery.

CONCLUSION

Artificial intelligence has significantly transformed experimental pharmacology by improving drug screening efficiency and accuracy. By integrating AI with traditional experimental methods, researchers can accelerate drug discovery and improve clinical outcomes. Continued advancements in AI technology will further enhance its role in pharmacology.

ABSTRACT

The edge colouring of graphs has many practical applications in Network theory, scheduling and optimization problems. One of the emerging concepts in the theory of edge colouring is the edge-chromatic critical graphs. The classification of graphs using edge colouring is an area which needs attention, as there is no specific mechanism found so far, to classify the graphs. The study of edge-chromatic critical graphs helps significantly in the classification of graphs. The edge-chromatic critical graphs up to order 14 were studied by researchers in various research articles. In this article, we study the structure of edge-chromatic 6-critical graphs of order 15 with minimum degree at least 4.

Keywords: edge-chromatic critical graphs, edge-chromatic 6-critical graphs

INTRODUCTION

Colouring of all the edges of a graph in such a way that the adjacent edges are coloured with different colours is called an edge colouring of the graph. The minimum count of colours needed to have an edge colouring is called its edge choromatic number or chromatic index. The famous renowned mathematician Vizing [1] proved that, for any simple graph G, the edge chromatic number is either its maximum degree or one more than its maximum degree. A graph can be classified using its edge chromatic number. A graph is called Class One graph if its edge chromatic number is its maximum degree and it is called as Class Two graph if its edge chromatic number is one more than its maximum degree. So far, there is no algorithm or mechanism developed to identify directly whether the given graph is of Class One or Class Two. A graph is called edge-chromatic critical if it is connected Class Two graph such that

removal of any of its edges results in the decrease of edge chromatic number. The study of edge-chromatic critical graphs plays a vital role in the classification of graphs. If the maximum degree of the edge-chromatic critical graph is Δ , then the graph is called Δ –critical.

Notations

In this article, G represents a simple graph with order n and size m . The set of all major vertices is denoted by M and N denotes the set of all minor vertices. The maximum degree of the graph is denoted by Δ and the minimum degree is denoted by δ . The number of vertices of degree i is denoted by n_i. The degree sequence of an edge-chromatic critical graph G is represented by $\pi(G) = 2^{n_2}3^{n_3}4^{n_4}5^{n_5}6^{n_6}$. The set of all edges with one end in M and the other end in N is denoted by $[M,N]$ and $|[M,N]|$ denotes the number of edges in $[M,N]$.

Known Results

The following Lemma guarantees a minimum count of major vertices of an edge-chromatic critical graphs which plays an important role in the study of edge-chromatic critical graphs. We often use this lemma in this article. Vizing's Adjacency Lemma (VAL)[2]: In a Δ – critical graph G, if vw is an edge and d(v) = k , then w is adjacent with at least Δ - k +1 other vertices of degree Δ . In particular, G has at least Δ - δ +2 vertices of degree Δ. Vizing [3] conjectured that, the size of any simple edge-chromatic Δ-critical graph is at least $\frac{1}{2}\left[(\Delta-1)n+3\right]$ and this conjecture has been verified for simple edge-chromatic critical graphs with maximum degree up to 6. [4,5,6,7]

MAIN RESULTS

In this section, we study the structure of edge-chromatic 6-critical graphs with minimum degree at least 4. By VAL (2.1), for any edge-chromatic Δ-critical graph, $n_\Delta \geq \Delta - \delta + 2$. Hence, for any edge-chromatic 6-critical graph, $n_6 \geq 6-4+2=4$ if the minimum degree of the graph is 4 and $n_6 \geq 6-5+2=3$ if the minimum degree of the graph is 5. From (2.2), for any edge-chromatic 6-critical graph, $2m \geq \left[(6-1)\times 15+3\right]=78$.

Edge- chromatic 6-critical graphs of order 15 with minimum degree 4

Let G be an edge-chromatic 6-critical graph of order 15 with minimum degree 4. Then $n_6 \geq 4$. If $n_6 = 4$, then $n_4 + n_5 = 11$ and n_5 is even. Since each 6-vertex can be adjacent with at most 4 minor vertices, $|[M,N]| \leq 4\times 4 = 16$. Since $n_4 + n_5 = 11$ and each minor vertex must be adjacent with atleast two major vertices, $|[N,M]| \geq 11\times 2 = 22$, a contradiction. Thus $n_6 \neq 4$. If $n_6 = 5$, then $n_4 + n_5 = 10$ and n_5 is even. In the case of $n_5 \leq 6$, we notice that $2m \leq (4\times 4)+(6\times 5)+(5\times 6) = 76$, a contradiction. Hence, $n_5 = 8$ (or) 10.If $n_5 = 8$, then the possible degree sequence is $4^2 5^8 6^5$. Since $n_6 = 5$ and the minimum degree is 4, we get that $n_5 \neq 10$. If $n_6 = 6$, then $n_4 + n_5 = 9$ and n_5 is even. In the case of $n_5 \leq 4$, we notice that $2m \leq (5\times 4)+(4\times 5)+(6\times 6) = 76$, a contradiction. Hence, $n_5 = 6$ (or) 8. Thus, the possible degree sequences are $4^3 5^6 6^6$ and $4^1 5^8 6^6$. If $n_6 = 7$, then $n_4 + n_5 = 8$ and n_5 is even. In the case of $n_5 \leq 2$, we notice that $2m \leq (6\times 4)+(2\times 5)+(7\times 6) = 76$, a contradiction. Hence, $n_5 = 4$ (or) 6 (or) 8.Since $n_6 = 7$ and the minimum degree is 4, we see that $n_5 \neq 8$. Thus, the possible degree sequences are $4^4 5^4 6^7$, $4^2 5^6 6^7$ .If $n_6 = 8$, then $n_4 + n_5 = 7$ and n_5 is even. In the case of $n_5 = 0$, we

notice that $2m = (7 \times 4) + (8 \times 6) = 76$, a contradiction. Hence, $n_5 = 2$ (or) 4 (or) 6. Thus, the possible degree sequences are $4^5 5^2 6^8$, $4^3 5^4 6^8$ and $4^1 5^6 6^8$.If $n_6 = 9$, then $n_4 + n_5 = 6$ and n_5 is even. Hence, $n_5 = 0$ (or) 2 (or) 4 (or) 6.Since $n_6 = 9$ and the minimum degree is 4, we see that $n_5 \neq 6$. Thus, the possible degree sequences are $4^6 6^9, 4^4 5^2 6^9$, $4^2 5^4 6^9$.If $n_6 = 10$, then $n_4 + n_5 = 5$ and n_5 is even. Hence, $n_5 = 0$ (or) 2 (or) 4. Thus, the possible degree sequences are $4^5 6^{10}, 4^3 5^2 6^{10}$ and $4^1 5^4 6^{10}$.If $n_6 = 11$, then $n_4 + n_5 = 4$ and n_5 is even. Hence, $n_5 = 0$ (or) 2 (or) 4.Since $n_6 = 11$ and the minimum degree is 4, we see that $n_5 \neq 4$. Thus, the possible degree sequences are $4^4 6^{11}, 4^2 5^2 6^{11}$.If $n_6 = 12$, then $n_4 + n_5 = 3$ and n_5 is even. Hence, $n_5 = 0$ (or) 2. Thus, the possible degree sequences are $4^3 6^{12}$ and $4^1 5^2 6^{12}$.If $n_6 = 13$, then $n_4 + n_5 = 2$ and n_5 is even. Hence, $n_5 = 0$ (or) 2.Since $n_6 = 13$ and the minimum degree is 4, we see that $n_5 \neq 2$.Thus, the possible degree sequence is $4^2 6^{13}$. If $n_6 = 14$, then $n_4 + n_5 = 1$ and n_5 is even. Hence, $n_5 = 0$. Thus, the possible degree sequence is $4^1 6^{14}$. If $n_6 = 15$, then $n_4 + n_5 = 0$ which implies that $n_4 = n_5 = 0$, a contradiction, as the minimum degree is 4. Thus, if G is an edge-chromatic 6-critical graph of order 15 with minimum degree 4, then $\pi(G) \in \{ 4^2 5^8 6^5, 4^3 5^6 6^6, 4^1 5^8 6^6, 4^4 5^4 6^7, 4^2 5^6 6^7, 4^5 5^2 6^8, 4^3 5^4 6^8, 4^1 5^6 6^8, 4^6 6^9, 4^4 5^2 6^9, 4^2 5^4 6^9, 4^5 6^{10}, 4^3 5^2 6^{10}, 4^1 5^4 6^{10}, 4^4 6^{11}, 4^2 5^2 6^{11}, 4^3 6^{12}, 4^1 5^2 6^{12}, 4^2 6^{13}, 4^1 6^{14} \}$.

From the list derived above, we observe the following.

- If G is an edge-chromatic 6-critical graph of order 15 with minimum degree 4 and $n_4 = 1$, then $\pi(G) \in \{4^1 5^8 6^6, 4^1 5^6 6^8, 4^1 5^4 6^{10}, 4^1 5^2 6^{12}, 4^1 6^{14}\}$
- If G is an edge-chromatic 6-critical graph of order 15 with minimum degree 4 and $n_4 = 2$, then $\pi(G) \in \{4^2 5^8 6^5, 4^2 5^6 6^7, 4^2 5^4 6^9, 4^2 5^2 6^{11}, 4^2 6^{13}\}$
- If G is an edge-chromatic 6-critical graph of order 15 with minimum degree 4 and $n_4 = 3$, then $\pi(G) \in \{4^3 5^6 6^6, 4^3 5^4 6^8, 4^3 5^2 6^{10}, 4^3 6^{12}\}$
- If G is an edge-chromatic 6-critical graph of order 15 with minimum degree 4 and $n_4 = 4$, then ' $\pi(G) \in \{4^4 5^4 6^7, 4^4 5^2 6^9, 4^4 6^{11}\}$
- If G is an edge-chromatic 6-critical graph of order 15 with minimum degree 4 and $n_4 = 5$, then $\pi(G) \in \{4^5 5^2 6^8, 4^5 6^{10}\}$
- If G is an edge-chromatic 6-critical graph of order 15 with minimum degree 4 and $n_4 = 6$, then $\pi(G) = 4^6 6^9$
- There is no edge-chromatic 6-critical graph of order 15 with minimum degree 4 and $n_4 \geq 7$

Edge - chromatic 6 - critical graphs of order 15 with minimum degree 5

Let G be an edge-chromatic 6-critical graph of order 15 with minimum degree 5. Hence $n_6 \geq \Delta - \delta + 2 = 6 - 5 + 2 = 3$. Since n_5 is even and the order of the graph is 15, n_6 is odd. If $n_6 = 3$, then $n_5 = 12$. Since each 6-vertex can be adjacent with at most 4 minor vertices, $|[M, N]| \leq 3 \times 4 = 12$. Since $n_5 = 12$ and each minor vertex must be adjacent with at least two major vertices, $|[N, M]| \geq 12 \times 2 = 24$, a contradiction. Thus

$n_6 \neq 3$.Since the minimum degree is 5, $n_6 \neq 15$. Hence the possible degree sequences are $5^{10}6^5$, $5^8 6^7$, $5^6 6^9$, $5^4 6^{11}$ and $5^2 6^{13}$. Thus, if G is an edge-chromatic 6-critical graph of order 15 with minimum degree 5, then $\pi(G) \in \{5^{10}6^5, 5^8 6^7, 5^6 6^9, 5^4 6^{11}, 5^2 6^{13}\}$.

From the list derived above, we observe the following.

- There are only five different possibilities of degree sequences of edge-chromatic 6-critical graphs of order 15 with minimum degree 5
- Since the number of odd degree vertices is even, there is no edge-chromatic 6-critical graph of order 15 with odd number of minor vertices
- There is no edge-chromatic 6-critical graph of order 15 with even number of major vertices

Remark: From 4.1 and 4.2, we observe that, if G is an edge-chromatic 6-critical graph of order 15 and minimum degree at least 4, then

$\pi(G) \in \{ 4^2 5^8 6^5, 4^3 5^6 6^6, 4^1 5^8 6^6, 4^4 5^4 6^7, 4^2 5^6 6^7, 4^5 5^2 6^8, 4^3 5^4 6^8, 4^1 5^6 6^8, 4^6 6^9, 4^4 5^2 6^9, 4^2 5^4 6^9, 4^5 6^{10}, 4^3 5^2 6^{10}, 4^1 5^4 6^{10}, 4^4 6^{11}, 4^2 5^2 6^{11}, 4^3 6^{12}, 4^1 5^2 6^{12}, 4^2 6^{13}, 4^1 6^{14}, 5^{10}6^5, 5^8 6^7, 5^6 6^9, 5^4 6^{11}, 5^2 6^{13}\}$.

CONCLUSION

As numerous studies have investigated edge-chromatic critical graphs of order up to 14, the present article extends this line of research to edge-chromatic critical graphs of order 15. In particular, it examines the structural properties of edge-chromatic 6-critical graphs with minimum degree at least 4. Furthermore, all possible degree sequences of such graphs are determined.

ABSTRACT

Handball performance depends on a combination of balance, coordination, agility and sport-specific skills. BOSU Ball training has emerged as an effective method for enhancing neuromuscular control and functional performance in athletes. To compare the effects of BOSU Ball training and sport-specific training on selected performance variables among collegiate handball players. Forty-five male handball players (18–25 years) from colleges affiliated with Kannur University, Kerala, India, were randomly selected and assigned into three groups (n = 15 each): BOSU Ball Training Group (BBTG), Sport-Specific Training Group (SSTG) and Control Group (CONTG). A true randomized pre-test–post-test group design was adopted. The experimental groups underwent their respective training programmes for 12 weeks, while the control group did not receive any structured training. Performance variables (passing and dribbling) were assessed using coaches' ratings. The data were analysed using Analysis of Covariance (ANCOVA) followed by Scheffé's post hoc test at the 0.05 level of significance. Both BOSU Ball training and sport-specific training produced significant improvements in passing and dribbling performance compared with the control group ($p < 0.05$). BOSU Ball training demonstrated significantly greater improvements than sport-specific training in both performance variables. A 12-week BOSU Ball training programme is more effective than conventional sport-specific training in enhancing passing and dribbling performance among collegiate handball

players. Incorporating BOSU Ball exercises into regular handball training may improve functional performance and competitive success.

Keywords: BOSU Ball training, sport-specific training, handball, passing, dribbling, performance, collegiate players, ANCOVA.

INTRODUCTION

Handball is a fast and intermittent team sport with many sprinting, jumping, throwing, and tackling phases with rapid change of direction with repeated contact. An effective handball play is based on different physical, physiological and psychological elements: muscular strength, explosive power, agility, balance, coordination, speed, endurance and reaction time and decision-making ability (Povoas et al., 2012; Wagner et al., 2014). Players during competition performed explosive movements and controlled postural stability within dynamic and unpredictable conditions. For the benefit of athletes, neuromuscular preparation has become a key feature in an athletic conditioning program, not only because of the way it encourages the nervous and muscular systems to come together more easily but also to develop greater movement quality, proprioception, balance, muscular coordination and postural control. Good neuromuscular control increases the efficiency with which individuals can contract quickly but also maintains body stability during extreme athletic manoeuvres. These adaptations are especially relevant in handball, as players commonly utilize multidirectional accelerations, decelerations, cutting maneuvers, and landing activities requiring a high level of musculoskeletal load (Myer et al., 2006; Behm & Anderson, 2006). Enhancement of neuromuscular coordination not only improves agility but also helps to facilitate appropriate movement patterns to minimize the chances of lower extremity injuries (Hubscher et al., 2010). Despite the fact that BOSU Ball training is one of the most widely adopted functional training methods capable of achieving simultaneous benefits from balance, core stability, proprioception, and muscle coordination improvements, the athlete's response to BOSU Ball training has been slow and erratic.

The BOSU Ball sports an inflatable hemispherical dome on the rigid surface, providing an unstable surface which challenges the body's balance mechanisms. To train on unstable surfaces, the remaining stabilizing muscles, especially those in the trunk, hips, knees and ankles, must be continuously activated. Results: this produces greater changes at this level than normal stable-surface exercises (Behm & Colado, 2012). Because the biomechanical instability it creates when conducting BOSU Ball exercises stimulates proprioceptors and sensorimotor function; athletes thus have a better chance of improved control over movement dynamics stability and functional power. Some research has found an enhancement in athletic performance with instability training. Behm and Colado (2012), for example, demonstrated stability on the surface increases balance, coordination, proprioception, core muscle activation to great extent. Granacher, Muehlbauer and Gollhofer (2011) noted that balance training improves postural control and functional effectiveness throughout athletic groups. Like the findings of Kibler, Press and Sciascia (2006) which focused on core stability, it is also associated with effective and quick force transfer between the upper and lower extremities during sports activities. According to Willardson (2007), core stability training strengthens trunk muscular endurance, improving performance by optimizing movement efficiency and reducing biomechanical inefficiencies. These adaptations might be of particular value for handball players, as almost every technical action relies upon effective trunk stabilization and body control.

At all times during offensive play, throwing overhead throws, pivoting shots, jumping and acceleration combine forces from jump to jump as well as turning toward an opponent, while playing at the same time maintaining a balanced position under defense. From the standpoint of defense, players must perform sudden lateral movements and sudden stops, tackles, turns of direction, and so on, without compromising their ability to stabilize. Because of strong core muscles and postural control they offer the right type of throwing technique, better jumping and landing skills, great sprinting ability and greater defense positioning. Furthermore, the increase in proprioception and joint stability might decrease the occurrences of handball-related ankle and knee injuries, two of the most common. (Behm

& Colado, 2012; Myer et al., 2006). Sports-specific training is still one of the most effective methods for improving the quality of performance in competitive sports. Sport-specific training includes exercises that resemble the movement patterns, technical skills, tactical situations, requirements of the sport, and physical performance experienced in competition. In handball, the drills usually include passing, shooting, dribbling, defensive footwork, running, agility, reaction drills, small-sided play, small-sided games, and tactical exercises. By playing under match-play conditions, it is easier for athletes to build skills in technical excellence, tactical knowledge, decision-making skills and to move effectively (Bompa & Haff, 2009). Specificity is the principle according to which training adaptations are well-determined based on the individual exercises.

Therefore, exercises that closely resemble competition's biomechanical, physiological and metabolic demands produce the greatest transfer to sporting performance (Bompa & Haff, 2009; Stone, Stone, & Sands, 2007). Sport-specific training does not only enhance skill execution but rather contributes to sport-specific physical capacities of agility, acceleration, explosive power, reaction speed and also coordination. Young and Farrow (2006) went on to argue, in a similar vein, that agility performance does depend on a balance between physical attributes for sports performance as well as on perceptual cognitive abilities, and that such a combined state of being is effectively facilitated by sport specific practice. Recent advancements in sports science emphasize the significance of embedding functional instability training in sport-specific skills as opposed to having them function as separate training interventions. BOSU Ball exercises enhance the core stability while proprioception, neuromuscular coordination and postural control, while the sport-specific drills allow the athletes to apply these adaptations to competitive handball gameplay. The combined use of these methods should produce adaptive synergisms on the other hand which improve efficacy of movement, dexterity and sport performance. Enhanced balance and neuromuscular control that BOSU Ball training provides may lead to better throwing, passing, sprinting and defensive movements performed in sport specific sessions. While BOSU ball training has shown beneficial effects of these specific practices on balance, stability, and functional performance in a variety of athletic populations, few studies have investigated BOSU Ball-based combined interventions with sport-specific training with handball athletes. The bulk of prior studies have explored these interventions independently, thus providing only limited evidence of their synergistic effect on performance-related variables. Due to the diverse physical demands of handball combined approach BOSU Ball and sports specific training might be used as evidence for coaches, sports scientists as well as of strength and conditioning professionals looking using evidence based approaches in improving athletic performance and reducing risk of injuries. Accordingly, the objective of this study was to determine the benefit of two sport specific BOSU Ball training on specific performance factors in handball players.

REVIEW OF LITERATURE

The recent evidence from sports science studies has indicated the role of functional training to enhance neuromuscular coordination, balance, and sport-specific performance. Focusing extensively on the development of unstable surfaces, especially the BOSU Ball exercises to increase athletic performance and decrease injury risk became a main motivation in research. The studies below show a holistic study of BOSU Ball training, instability resistance training, and sport-specific training. Salam et al., (2024) presented a mini review for investigating the efficacy of BOSU Ball training on athlete balance performance. The review included studies from between 2022 and 2023 on sports participants. The results of the present study clearly indicated that BOSU Ball training consistently improved static and dynamic balance due to significant improvements on proprioception, neuromuscular coordination and postural stability. BOSU Ball exercises are efficient in the development of balance and movement control, such that it may apply to inclusion in athletic training programmes, was suggested in the review. Akbar et al., (2024) conducted a systematic review of the effects different exercise training interventions produced in different exercises on physical fitness and technical skill in handball players. Sixteen experimental studies were investigated and to assess the overall effectiveness of training techniques. This review revealed that the key performance variables that were most commonly enhanced after structured exercise programmes were balance, agility, speed and jumping ability as

performance variables. According to the authors, a balance of functional conditioning and the execution of sport-specialised drills leads to a better improvement in handball overall in comparison to traditional training alone.
Gao et al., (2025) conducted a systematic review of instability resistance training in athletes to assess its effect on balance performance. The review encompassed twenty studies comprising athletes from various sports such as handball, basketball, volleyball, soccer, gymnastics and badminton. Results showed that dynamic stability and stability resistance training with a mixture of BOSU Balls, Swiss Balls, wobble boards, balance pads, and suspension systems improved static, dynamic, and reactive balance by a significant amount. The authors concluded that instability training is an effective approach in activating deep stabilising muscles, proprioception, and neuromuscular control that improves proprioception and neuromuscular control, thereby reducing the chance of injury and improving athletic performance. Gao, Abdullah and Omar Dev (2024) systematically reviewed and analysed their analyses of the effects of instability resistance training on core muscle strength in the athletes. A review reported that unstable surface training increases isometric, isotonic, and isokinetic core muscle strength significantly in any sports population. Unstable environments are said to increase activation of the trunk stabilizers and coordination between agonist and antagonist muscles. These modifications lead to increased postural control, movement efficiency and functional athletic performance.

Kurtoglu et al., (2024) looked into an 8-week BOSU Ball exercise programme, core strength endurance and balance. This study revealed that individuals who practice BOSU Ball exercises have better trunk muscular endurance and dynamic balance than the control group in the study. The researchers indicated that unstable surface exercises are likely to promote greater activation of central musculature and therefore superior functional adaptation for better stability of body and movement control. Frontiers in Sports and Active Living (2024) had a meta-analysis examining the impact of small-sided game training on lower extremity explosive power in handball players. The review revealed that game-based sport-specific training resulted in significant improvements in explosive power, agility, sprint and technical efficiency levels as it imitates the physiological and tactical demands of competitive handball very closely. The authors suggested adding small-sided games to normal training programmes for increasing physical fitness as well as performance, since the two may coexist. Recent data also indicates that combining instability training together with sport-specific drills has greater clinical gains than the two independent procedures. Instability training to work upon core stability, proprioception, postural control and sport-specific drills to strengthen technical skills and tactical execution in real competition. This integrative model of training translates improvements to the physical characteristics of sports activities to improve efficiency of motion, balance while executing the skills and physical competence in general.

MATERIALS AND METHODS

Research Design
The present study adopted a true experimental pre-test and post-test randomized group design.

Participants
Forty-five male handball players (18–25 years) from colleges affiliated with Kannur University, Kerala, India were randomly selected and assigned into three groups (n = 15 each): BOSU Ball Training Group (BBTG), Sport-Specific Training Group (SSTG) and Control Group (CONTG).

Inclusion Criteria
- Male handball players aged 18–25 years.
- Players representing their respective college handball teams.
- Minimum of one year of competitive handball playing experience.
- Apparently healthy and medically fit to participate in vigorous physical activity.
- Regular participation in handball practice and competitions.
- Willingness to participate throughout the entire training period.

- Provision of written informed consent prior to participation.

Exclusion Criteria

- History of musculoskeletal injury or surgery during the previous six months.
- Any neurological, cardiovascular, respiratory, or orthopedic disorder affecting performance.
- Current participation in any additional structured strength, balance, or conditioning programme outside the study.
- Irregular attendance during the intervention period (less than 90% attendance).
- Failure to complete either the pre-test or post-test assessments.
- Use of performance-enhancing substances or medications that could influence physical performance.

Selection of Variables

Skill performance variables such as passing and dribbling were assessed using subjective rating.

Pilot Study

A pilot study was run on a representative sample of handball players to assess the feasibility and fit of selected tests. The testing procedures were adapted according to the findings.

Statistical Analysis

To determine the effectiveness of the interventions while controlling for baseline differences, Analysis of Covariance (ANCOVA) was employed. Whenever the adjusted post-test means showed significant differences, Scheffe's post hoc test was applied to identify pairwise group differences. The level of statistical significance was set at 0.05 for all analyses. A one-way ANCOVA was used to compare the effect of BOSU Ball training, sport-specific training and the control condition on passing performance after adjusting for pre-test results. Pre-test scores between the groups did not differ significantly, $F(2, 42) = 1.57$, $p > .05$. However, significant differences were found for post-test scores, $F(2, 42) = 25.31$, $p < .001$, in adjusted post-test scores, $F(2, 41) = 24.12$, $p < .001$. These results demonstrate that the training interventions improved passing compared to the control. Quite a few comparisons between the adjusted means of BBTG and SSTG (4.80), BBTG and CONTG (11.65) and SSTG and CONTG (6.85) with the CI of 4.21. A one-way ANCOVA was used to compare the effect of BOSU Ball training, sport-specific training and the control condition on dribbling performance after adjusting for pre-test results. Pre-test scores between the groups did not differ significantly, $F(2, 42) = 0.64$, $p > .05$. However, significant differences were found for post-test scores, $F(2, 42) = 14.90$, $p < .001$, in adjusted post-test scores, $F(2, 41) = 14.91$, $p < .001$. These results demonstrate that the training interventions improved dribbling compared to the control. Quite a few comparisons between the adjusted means of BBTG and SSTG (4.26), BBTG and CONTG (10.31) and SSTG and CONTG (6.05) with the CI of 4.17.

Effects of BOSU Ball training, sport-specific training and a control condition on selected handball performance variables, passing and dribbling were evaluated in this study. The covariance analysis showed that there were no differences between the groups at the pre-test levels for either passing or dribbling, implying the similarity of the groups before the intervention. Nevertheless, meaningful differences persisted on post-test and adjusted post-test means, which indicated that the training interventions had a great effect on the handball performance. For passing, the best improvement occurred in the BOSU Ball training group, the sport-specific group made the next most improvement, with very few changes recorded in the control group. For adjusted means the highly significant F ratios suggested that BOSU Ball training led to improvement in passing performance. This improvement may be likely to be the result of an effect of instability training on neuromuscular coordination, balance and core stability, which are necessary for accurate and coordinated passing in handball (American College of Sports Medicine, 2018; Behm & Colado, 2012). So, the results for dribbling also showed a significant improvement in the experimental groups compared to the control subjects and the advantage of BOSU Ball training group was shown in both groups, again better. The following Scheffé post hoc analysis confirmed the statistical significance of all paired comparisons between groups, confirming that in general BOSU Ball and sport-specific training for both groups were sufficient to produce a significant statistical change in both groups. The large increase the BOSU Ball group experienced could

mean an improved proprioceptive ability and balance that is essential for preserving the ball's control whilst making quick changing of direction. Exercises designed to control instability are thought to involve activating stabilizer muscles and improve motor control, which assists with mastering difficult sport-specific activities such as dribbling processes (Behm & Colado, 2012). Sport-specific training by contrast, also had a major role to play in performance improvements by enhancing technical precision and dynamics of movement that were relevant for the game to the player (Bompa & Haff, 2009). It has been argued that in any case, it was found that both BOSU Ball training and sport-specific training are able to improve handball performance variables, though BOSU Ball training provided a greater performance gain compared to sport-specific training. It is supported by the findings, the results suggest that adding balance and instability training to conventional training program can improve neuromuscular efficiency and skill performance. This is in agreement with previous studies which suggest, as much as possible, that functional and instability training increases athletic performance through coordination, balance and muscular control (American College of Sports Medicine, 2018).

CONCLUSION

- There was no significant difference between the groups in the pre-test indicating initial homogeneity.
- Significant enhancements in passing and dribbling were noted following the 12-week training programme. Both BOSU Ball Training and Sport-Specific Training significantly increased handball performance compared to the Control Group.
- The BOSU Ball Training Group resulted in more improvement compared with the Sport-Specific Training Group.
- BOSU Ball training was the most effective technique to promote passing and dribbling of handball players.

ACKNOWLEDGEMENT

The authors would like to extend their deep gratitude to handball players, Directors of Physical Education, Coaches and experts for their ideas and cooperation to conduct this study successfully.

Conflict of Interest

The authors announce that there is no conflict of interest regarding the publication of this study.

ABSTRACT

Rapid developments in the field of cloud computing and cross-cloud data transfer have greatly improved the data availability, resource sharing, and collaboration. However, there are increasing concerns about security and privacy threats, such as unauthorized data access, metadata leakage, and forensic analysis of the sensitive data. There are mainly four approaches used in the area of cloud computing security, namely certificate free authentication, encryption, metadata monitoring, and anomaly detection, that guarantee security of data during its transferring process. While all these approaches provide necessary confidentiality, integrity, and access control, there is still a problem of exposing metadata, which can be obtained by an attacker even though the data itself is encrypted. In order to overcome this limitation, we propose MN-EMSDT (Meaningful Noise-Based Embedded Metadata Protection for Secure and Privacy-Preserving Cross-Cloud Data Transfer). In the proposed solution, we increase the level of confidentiality of the metadata before the process of encryption. First, we identify High Security Data (HSD) in the input file and produce context-aware Meaningful Noise using insertion of the word, word rearrangement and punctuation change. Consequently, the entire file, which comprises the original data, Meaningful Noise, and embedded metadata, is encrypted as a single secure entity before transmission. At the receiving end, only authorized users or groups can be able to decrypt the secure file, retrieve the embedded metadata, eliminate the Meaningful Noise, and reconstruct the original data accurately. By combining embedded metadata security with unified file encryption, the proposed technique reduces the exposure of metadata, eliminates the need for external metadata, increases data security, and facilitates secure cross-cloud data transfer.

Keywords: Cloud Security, Cross-Cloud Data Transfer, Meaningful Noise, Embedded Metadata, Metadata Protection, Secure File Transfer, Information Privacy, Data Confidentiality, Access Control, Encryption

INTRODUCTION

Some cloud security situation awareness methodologies have been proposed to detect and analyze security threats in cloud environments. They facilitate better monitoring of the network and early detection of abnormal security incidents. Nonetheless, such methodologies are geared toward threat analysis and network security without addressing the issue of confidentiality of metadata created through the transfer of data [1]. Machine learning and threat intelligence have become widely used for enhancing cloud security by detecting any malicious actions and threats. They help detect security threats and ensure proactive management of cloud security. Nonetheless, such techniques have nothing to do with metadata confidentiality while data is transferred [2]. Use of multi-factor authentication along with adaptive cryptography ensures greater protection against access to cloud services. Machine learning may assist in improving the process of authentication and encryption decisions depending on security conditions. Nonetheless, authentication and encryption alone cannot help prevent metadata leakage [3]. The survey studies of cloud security issues have outlined numerous threats in the cloud environment and proposed several ways of mitigating these threats by means of such tools as access control, encryption, authentication, and security monitoring. These mechanisms offer significant security for the data and services hosted in the clouds. Still, metadata leakage during data transmission is one of the privacy concerns that require further protection beyond the traditional mechanisms of cloud security [4].

The use of metadata-embedding techniques has shown how information may be embedded into digital content for tracking and management. This shows how possible it is to embed the metadata directly into content instead of keeping it separately. Still, the use of metadata embedding for digital rights tracking does not solve the issue of secure cloud data transfer or the protection of sensitive reconstruction metadata by unified encryption [5]. Several research works have studied metadata integration mechanisms in various applications as a way of improving the data organization and management. This research shows some problems of metadata generation, integration, consistency, and management. Still, the problem of protecting metadata from leakage during secure cloud data transfer requires a separate privacy mechanism [6]. Secure cross-cloud synchronization mechanisms have been proposed to protect data while transferring information between different cloud environments. Hardware-assisted protection and encrypted synchronization can strengthen confidentiality during cross-cloud communication. But these types of methods mainly focus on securing the transferred data and do not consider the problem of revealing sensitive metadata related to the transferred data [7]. Blockchain-enabled cross-domain data transfer methods can offer security, traceability, and secure communication in the context of industrial IoT, which include both edge and cloud computing services. However, distributed verification can be used for increasing trust in different domains during data transfer. But, these types of techniques might not be effective enough in protecting content-specific metadata from being exposed to information leakage, even when such metadata may contain sensitive information without having any access to the encrypted data [8]. Privacy-preserving approaches based on noise generation have been proposed to prevent sensitive information leakage. The use of controlled noise demonstrates the potential of data transformation as a privacy protection mechanism. However, conventional noise-based approaches do not specifically combine meaningful content transformation with embedded reconstruction metadata and unified encryption for secure cloud data transfer [9].

Decentralized identity and verifiable credentials-based access control systems ensure secure identity management and authentication in distributed network environments. Access control techniques allow limiting resource access to authorized entities only. But access control systems are focused on access restriction and do not prevent information about data transfers from being leaked [10]. Zero trust access control is a technique which ensures constant security enforcement based on a session lifecycle and access to protected resources. Such an approach enhances the authorization process as it avoids inherent trust in distributed environments. But zero trust access control does not provide for protection of the metadata of transferred files [11]. Attribute based encryption allows achieving access control to cross-domain resources via encryption and decryption of information based on predefined attributes of users. Such cryptographic systems are well-suited for collaborative environments with many users or domains

involved. But such cryptography systems provide no metadata protection when transferring files [12]. Select-aggregate cryptographic solutions have also been proposed to facilitate data sharing by multiple users along with the effective management and revocation of decryption keys in cloud computing scenarios. Such solutions enhance selective access of the data stored in the cloud and minimize the problems associated with multiple keys management. Nevertheless, such solutions mainly deal with key management issues and not with securing metadata generated from the transformed data [13].

Related Work

S. Davis et al. (2024) have suggested an in-situ privacy technique utilizing mixed-signal perturbation and hardware-secure data reversibility. The technology utilizes perturbation as a means of providing data protection while at the same time allowing for recovery of the initial data in a secure way. This privacy technique through data transformation is applicable in MN-EMSDT since it provides an example of how to achieve data privacy without losing its recoverability property. Nonetheless, it does not provide for protection of embedded metadata while transferring data to the cloud environment [14]. H. A. D. L. Fuente-Anaya et al. (2026) have designed a privacy-preserving conformance checking technique using quantum-safe fully homomorphic encryption. This technique allows data analysis to be performed on outsourced data without compromising confidentiality of sensitive information. This technique illustrates how data transformation can be applied for achieving privacy and security while performing computations on data stored in the cloud environment. Nonetheless, it is more concerned with secure computation than with protection of transformation metadata [15]. L. Wang et al. (2023) proposed the development of a new technique called FABRIC that provides fast and secure unbounded cross-system encrypted data sharing for cloud computing. The proposed framework aims to solve the problems of secure sharing between different systems and the improvement of efficiency of encrypted data exchange. The cross-system encrypted communication of the FABRIC framework has much in common with the goal of MN-EMSDT regarding the secure data transfer. But it does not involve protecting any metadata that might contain confidential information while being transferred [16]. K. Negi et al. (2023) developed a novel approach to secure file storage based on a hybrid cryptography approach in cloud environments. Hybrid cryptographies help to achieve high security by using several cryptography techniques.

In this way, the file stored in the cloud environment can be protected from any unauthorized accesses. But the main aim of this approach was to make the file confidential [17]. J. Seo et al. (2024) have developed a self-sovereign and secure data sharing system employing Docker containers for machine learning on remote nodes. It focuses on secure and user-centric data sharing in a distributed computing environment ensuring security of data transferred with remote systems. This study proves the need for controlled data sharing in distributed cloud or containerized environments. It does not address the problem of metadata leak or reversible meaningful noise transformation in secure data transfer [18]. B. Zhu and L. Niu (2026) created a blockchain-based privacy-preserving data retrieval framework for outsourcing sensitive data. It integrates blockchain-based techniques with privacy-preserving data retrieval techniques. Such an approach is relevant to cloud computing environments, where sensitive data must be accessed from the external storage securely. Privacy-preserving data retrieval is the primary concern here, instead of protecting embedded reconstruction metadata in file transfers [19]. A. Alamer (2025) suggested a consortium blockchain-based access control for privacy-preserving mobile crowd sensing. The access control uses a distributed blockchain framework for providing secure access control over shared sensing resources. This method shows the necessity of decentralization and security of resource sharing in distributed systems. However, access control is not enough for preventing metadata leakage caused by transferred files, and that is why there is a need for metadata protection in MN-EMSDT [20]. N. Farhadighalati et al. (2025) provided a systematic review of existing access control models, research progress, and related challenges.

The paper emphasizes the necessity of authentication, authorization, and fine-grained access control for protecting resources in distributed systems. These techniques are needed for MN-EMSDT since only authorized and authenticated participants can decrypt and recover protected files. However, access control only allows regulating access and cannot provide metadata confidentiality by itself [21]. A. Majeed and S. O. Hwang (2025) suggested the

adoption of a differentially private algorithm for dealing with the trade-off between truthfulness and privacy in mixed data outsourcing. The algorithm focuses on data balancing and the correlation between attributes for improved privacy protection as well as preserving useful information within outsourced data. It shows the applicability of data perturbation in controlling the amount of sensitive information disclosed. Nevertheless, the application of traditional differential privacy does not provide reversible content transformation that includes metadata in cloud data transmission [22]. V. Boiarkin et al. (2024) came up with a privacy-preserving user-centric data-sharing scheme aimed at offering users more control over the sharing of information. It concentrates on protecting privacy and the security of user data in data-sharing environments. The user-centric security model is applicable to MN-EMSDT because secure data sharing involves not only controlled access but also protection from unauthorized information leakage. However, it does not involve noise that makes sense, reconstruction metadata, and encryption in the process of data transfer [23]. Zhong et al. (2023) designed a reversible data hiding technique based on the principle of image interpolation that functions in the encrypted domain. The technique allows for the inclusion of extra information into the encrypted data while retaining the possibility to restore the exact initial information. The reversible data hiding technique presented in this paper is very much similar to MN-EMSDT since both techniques embed some auxiliary information into the protected information without any permanent changes to the original information. However, the technique specifically considers the encryption of images rather than the reversible meaningful noise technique and context-aware noise and metadata protection of cloud data [24]. Sanchol and Fugkeaw (2023) developed a fully outsourced signcryption scheme for mobile cloud computing systems. It is a cryptosystem that combines the encryption and digital signatures together with the attribute-based access control of outsourced cloud data. Such cryptographic mechanisms could provide confidentiality, integrity, and fine-grained authentication of cloud data sharing services. However, the technique does not directly consider the problem of metadata leakages and the meaningful noise technique of MN-EMSDT [25].

Research Gap

Most of the existing techniques to ensure secure transfer of data across clouds are based on mechanisms related to encryption, authentication, and access control to provide security to the confidential data. But in many cases, the transformation metadata is kept separate from the original data and hence remains exposed to metadata leakage and forensic attack. Also, the traditional technique does not incorporate the process of Meaningful Noise generation together with protection of the metadata before encryption, resulting in failure to hide sensitive information properly.

METHODOLOGY

The proposed Meaningful Noise-Based Embedded Metadata Secure Data Transfer (MN-EMSDT) technique facilitates the secure and privacy preserving cross-cloud data transfer through the integration of Meaningful Noise generation, embedded metadata security, unified encryption, and authorized data retrieval. Contrary to existing techniques, the MN-EMSDT technique incorporates the embedding of metadata into the single protected file before encryption without exposing the external metadata. The methodological aspects of the proposed technique include system architecture, functional modules, algorithm, and mathematical formulation.

System Architecture

The architecture of MN-EMSDT system includes three layers: Data Protection Layer, Secure Communication Layer, and Secure Data Recovery Layer, all of which contribute towards providing secure and privacy-preserving cross-cloud data transfer.

1) Data Protection Layer

This layer first classifies High Security Data (HSD), creates Meaningful Noise (MN), generates transformation metadata, embeds metadata inside the file and encrypts the entire file, thus creating Secure File (SF).

Secure Communication Layer
Secure File encryption results in encryption of the entire file. Hence, this encryption helps secure the file while being transferred through the communication channel.

Secure Data Recovery Layer
Before decrypting the secure file, the receiver first authenticates the user or the authorized group. The embedded metadata is then used to extract the information and remove the meaningful noise to recover the original data. Unauthorized user can only view the encrypted version of the data.

Functional Modules
The MN-EMSDT system involves five functional modules working together for secure, privacy-preserving and authorized cross-cloud data transfer.

Module 1: High Security Data Identification and Meaningful Noise Generation
This module performs analysis of the input file to detect HSD that needs to be protected. Then it generates MN through word insertion, word reordering, and punctuation modification in order to mask sensitive data before encryption.
Input: Input File (F)
Output: Protected High Security Data (PHSD)

Module 2: Metadata Generation and Embedding
This module captures all the Transformation MDs generated and embeds them securely into the same protected file. The embedding of metadata obviates the need for external storage of metadata and reduces leakage of metadata during transmission.
Output: Embedded Protected File (EPF)

Module 3: Unified Encryption and Data Transmission
During this module, the whole file will be cryptographically encapsulated through the encryption key which encompasses the original data, the Meaningful Noise, and also the metadata. The encrypted file will then be sent over the communication channel that has been secured.
Output: Secure File (SF)

Module 4: User Authentication and Authorization
On receipt of the secure file, the framework authenticates the requesting user or authorized group. Authentication is the prerequisite to continue the next step.
Authentication verifies:
- Authorized User
- Authorized User Group

Module 5: Original Data
On completion of the authentication process, the entire file is decrypted and metadata extracted and processed. The framework deletes Meaningful Noise and correctly reconstructs the original High Security Data. Unauthorized users can access only the protected encrypted version.

Algorithm 1: Meaningful Noise-Based Embedded Metadata Secure Data Transfer (MN-EMSDT)
Input
Input File (F)
Encryption Key (K)
Authorized User/Group (AU)

Output

Secure File (SF)
Original Data (OD) or Protected Encrypted Data
Begin
/* Sender-Side Protection */
1. Read the input file (F).
2. Identify High Security Data (HSD).
3. Generate Meaningful Noise (MN).
F_MN ← Generate Meaningful Noise (F,MN)
4. Apply Meaningful Noise by:
• Inserting meaningful words
F_MN ← Insert Meaning full Words (F,MN)
• Rearranging selected words
F_MN ← Rearranging Selected Words (F,MN)
• Modifying punctuation marks
F_MN ← Modifying Punctuation Marks (F,MN)
5. Generate Transformation Metadata (MD).
MD ← Generate Metadata(MN)
6. Embed Metadata (MD) into the protected file.
F_EM ← Embed Metadata(F_MN, MD)
7. Encrypt the complete file
(Original Data + Meaningful Noise + Embedded Metadata)
using encryption key (K).
E ← Encrypt(F_EM, K)
8. Generate Secure File (SF).
SF ← Create Secure File(E)
9. Transfer Secure File (SF).
/* Receiver-Side Processing */
10. Receive Secure File (SF).
11. Authenticate User/Authorized Group (AU).
Auth Status ← Authenticate(AU)
12. If Authentication = TRUE Then
Decrypt Secure File.
F_EM ← Decrypt(SF, K)
Extract Embedded Metadata.
MD ← Extract Metadata(F_EM)
Analyze Metadata.
MN_Info ← Analyze Metadata(MD)
Identify Meaningful Noise.
MN ← Identify Noise(F_EM, MN_Info)
Remove Meaningful Noise.
F_R ← Remove Noise(F_EM, MN)
Reconstruct Original Data (OD).
OD ← Reconstruct Original Data(F_R, MN_Info)
Display Original Data.
Display(OD)
Else
Display Protected Encrypted Data Only.
End If
End

The MN-EMSDT technique integrates the sender-side protection along with receiver-side processing in an efficient and secure manner. In this context, the system first identifies the high security data, creates meaningful noise, embeds the metadata, and encrypts the entire file before sending it to the other cloud server. On the receiving end, the authenticated user will be able to decrypt the file, retrieve the embedded metadata, eliminate the noise, and retrieve back the original data. Unauthenticated users will be allowed to see the encrypted version of the file only.
Figure 1 illustrates the Architecture of the MN-EMSDT technique. The file is processed on the sender side by first identifying the high security data, creating meaningful noise, embedding the metadata, and encrypting the entire file before transferring it securely. On the receiver side, the authenticated user will get back the original data, but the unauthenticated user will be able to access only the protected encrypted version of the data.

Experimental Setup

The proposed MN-EMSDT approach is developed in order to conduct an experiment for assessing secure and private cross-cloud data transfer. The experimental setup includes the sender, secure channel and the receiver. At the time of data transfer process, the framework recognizes HSD, produces meaningful noise, produces and embeds transformation metadata, and then encrypts the whole file for transferring it securely. The received file is decrypted by the authenticated user and then extracts the embedded metadata, removes the meaningful noise and reconstructs the original file, while the unauthorized user only gets access to the encrypted version of the file. The proposed approach is implemented in Java (JDK 17), Jakarta EE, Apache Net Beans IDE, Glass Fish Server, and MySQL in a Windows platform. The performance of the proposed approach is measured through encryption time, decryption time, metadata protection, original data reconstruction accuracy, access success rate of authorized user, prevention from accessing unauthorized user, and secure data transfer efficiency.

RESULTS AND DISCUSSION

To evaluate the efficiency of the proposed Method of Meaningful Noise-Based Embedded Metadata Secure Data Transfer (MN-EMSDT), the method has been examined in order to measure its efficacy for securing sensitive data and embedded metadata while transferring data securely across clouds. The experiment has proved that the proposed method effectively secures both the sensitive data and the embedded metadata, as the process encrypts them together as one entity. While the existing methods secure metadata and the actual data separately, the proposed method allows embedding the metadata into the same file, which significantly decreases the risk of the exposure and any further analysis of the metadata. It has been proved that the authenticated user is able to reconstruct the original data, decrypt the secure file, and remove the Meaningful Noise by using the embedded metadata. At the same time, the unauthorized user is not able to perform reconstruction of the original information and can use only the protected encrypted version. At the same time, the proposed method is highly efficient in terms of encryption and decryption, and provides efficient protection of the metadata as well. As can be seen from the comparison in Table 1, the suggested MN-EMSDT approach offers better security when compared to current techniques especially with respect to metadata security and access control. Through the encryption of metadata into the same file, there is no requirement for additional metadata storage and metadata leakage is greatly minimized. Also, file encryption and authentication allow for secure and privacy-preserving cloud-to-cloud data transfer. Figure 2 depicts the performance comparison of the proposed MN-EMSDT method with the existing methods in terms of various security assessment metrics. The improved performance of the proposed method in terms of metadata protection, resistance to metadata leakage, prevention of unauthorized access, and secure data transfer is demonstrated. This shows that the proposed MN-EMSDT provides better security and privacy along with the efficient cross-cloud data transfer.

CONCLUSION

In this paper, MN-EMSDT (Meaningful Noise-Based Embedded Metadata Protection for Secure and Privacy-Preserving Cross-Cloud Data Transfer) was presented, which is a new approach for improving secure cross-cloud

data transfer. The proposed method combines Meaningful Noise generation, embedded metadata protection, unified file encryption, and authenticated data reconstruction in a secure framework. By embedding the metadata inside the encrypted file, the proposed method reduces the exposure of metadata and provides improved data confidentiality.

ACKNOWLEDGEMENTS

We sincerely acknowledge the Head of the Department, Mrs. N. Vijayalakshmi, the Principal of the institution, Dr. P. Gajalakshmi and also thank our Institution for providing the infrastructure and research facilities that enabled the successful completion of this paper.

ABSTRACT

Implant placement is governed by the available bone. Many a time, implants have to be angulated to make maximum use of the available bone, especially in the maxillary arch where the alveolar bone anatomy is such that angulation becomes unavoidable. However, they need to be straightened by means of a prosthetic to make them esthetically and functionally useful. Dental implants placed at angulated positions require abutments that correct implant angulation without compromising crestal bone integrity.This study evaluates crestal bone loss around maxillary implants restored with angulated versus transmucosal abutments after three months of function using cone beam computed tomography (CBCT). Twenty maxillary implant sites were randomized to receive either angulated or transmucosal abutments. CBCT scans were performed three months post-prosthesis delivery to assess crestal bone levels at mesial, distal, buccal, and palatal aspects. Both groups exhibited comparable crestal bone loss with no statistically significant differences, except for minor variations at the palatal site. Angulated and transmucosal abutments effectively correct implant angulation without significantly affecting early

crestal bone loss. These findings support their clinical use in tilted implants, though further long-term studies are warranted to confirm these results.

Keywords: Angulated abutments, CBCT imaging, Crestal Bone loss, Transmucosal abutments

INTRODUCTION

Dental implants are widely used for replacement of missing teeth as they restore the masticatory efficiency to an extent which is comparable to that of natural dentition. [1] Implant placement depends on the availability of bone volume both in quantity and quality. A successful dental implant should show bone-to-implant integration that is known as osseo integration.[2] So, to evaluate the status of osseointegration and the success of dental implants, Albrektsson et al in 1986 introduced a criteria which states the following: (1)That an individual, unattached implant is immobile when tested clinically (2) That a radiograph does not present any evidence or peri-implant radiolucency (3) That after the implant's first year of service vertical bone loss will be 0.2 mm annually (4) That individual implant performance be characterized by an absence of persistent and/or irreversible signs and symptoms such as infections, pain, paresthesia, neuropathies or violation of the mandibular canal (5) That, a minimum criterion for success in the context of criteria 1-4, a successful rate of 85% should be at the end of a 5-yr observation period and 80% at the end of a 10-yr period. As bone volume is the single most important governing factor for the placement of dental implants, the dental surgeon may face some difficulties in rehabilitating edentulous areas, especially when associated with anatomical limitations due to reduced bone volume, particularly in the maxillary sinus area (maxilla) and inferior alveolar nerve area (mandible). Ideally, implants should be placed parallel to each other as well as to the adjacent teeth, and they should be vertically aligned with axial forces. At times, implants may need to be placed in angled positions, and this necessitates the use of angulated abutments in order to correct such angulations of the tilted implants. However, there is conflicting evidence regarding the use of angulated abutments; occlusal forces on the restorative crown or bridge can create different stress in the bone compared to straight abutments. Weinberg's research mathematically demonstrates that cusp inclination is the primary driver of torque generation. When occlusal force is applied, the resulting force line acts perpendicular to the cusp's surface. This relationship is critical because every 1mm of horizontal offset in a dentalimplant results in a 15% increase in torque stress[3]. The transmucosal abutments are designed to elevate the seating platform of the restoration from submucosal to supra-mucosal level, thus resulting in better prosthetics, especially in situations of diverging angled implants or angulated implants. Therefore, the aim of this study was to clinically and radiographically evaluate the effect of angulated and transmucosal abutments on crestal bone levels and to compare which one of the two abutments would be a better treatment option to preserve the crestal bone levels.

Aims and Objectives

This study evaluates crestal bone loss around maxillary implants restored with angulated versus transmucosal abutments after three months of function using cone beam computed tomography (CBCT).

MATERIAL AND METHODOLOGY

The patients were selected from the Outpatient Department of the Dept of Prosthodontics. Patients with bilaterally missing maxillary posteriors and willing for implants were considered.

Inclusion criteria:

- Age group between 3rd and 5th decades of life.
- No underlying systemic diseases.
- Non-smoker.
- With a full complement of teeth in the opposing arch.

Exclusion criteria:

- Individuals with uncontrolled systemic diseases like diabetes mellitus, hypertension, etc.
- Patients presenting with abuse of drugs or alcohol, or use of tobacco.
- Patients presenting with handicaps that would interfere with the ability to perform adequate oral hygiene or prevent completion of the study.
- Patients with immune compromised conditions, including HIV.

In the present study, A total of 20 sites were included in the maxillary arch (1st and 2nd quadrants). For the placement of dental implants, among 20 sites, 10 were randomly allocated to be loaded with angulated abutments while the other 10 were allocated to be loaded with transmucosal abutments by the flip of a coin. This was followed by evaluation of pre-operative and post-operative procedures using clinical and radiographic methods, which consisted of the patient's history, clinical examination, radiographic examination and blood investigations. All the patients were given a comprehensive verbal description of the treatment risks and advantages of implant therapy. A consent form duly signed by the patient was obtained before the implant surgery.

Fabrication of surgical guide stent

A surgical guide stent was fabricated based on the preoperative CBCT to correctly angulate the implant as per the pre-existing bone. This surgical guide stent was used for osteotomy site preparation and precise angulation of the pilot drill. It oriented the pilot drill for initial osteotomy site preparation and provided accurate placement of the dental implant. This surgical guide stent also stimulates the final emergence of the implant-supported prosthesis. The surgical guide stent was sterilised by using 2% glutaraldehyde solution prior to the surgery.

Stage 1 surgery

Implant success depends on complete aseptic conditions, which were strictly followed. Patients selected for the study were instructed to use chlorhexidine mouthwash 1week prior to the surgery. Patients were also instructed to have food and Augmentin 1000mg antibiotic 2 hours prior to surgery. Before the commencement of surgery, an initial RVG was made by placing the RVG sensor holder and adding silicone putty to register the bite index of the patient at the implant site. This bite index was preserved for later assessment of the implant site. A mid-crestal incision was performed at the implant site on the crest of the edentulous ridge with a #15 surgical blade. With a #9 Moult's periosteal elevator, a full-thickness mucoperiosteal flap was elevated. A bone measuring caliper was used to assess the buccolingual width of the implant site. After adequate exposure of crestal bone, the surgical guide stent was placed. The process of implant osteotomy was initiated with a pilot drill. After the initial punch with the pilot drill, the osteotomy site was prepared by sequential drilling with the help of the surgical stent. After preparation of the osteotomy site, the implant (ADIN TOUAREG-S TM Dental implant) was placed and tightened using a torque wrench.

Stage 2 surgery

To assess the crestal bone remodelling, patients were recalled after 3 months. Minimum exposure of the flaps was done, and the cover screw was removed from the implant. The RVG sensor holder with the customised bite index was placed at the same site in the patient's mouth, and an RVG was made. This RVG is now considered to be after 3 months from the initial phase of surgery and subjected to later evaluation. Followed by this, a gingival former was placed intra-orally.

Placement of Abutments: To correct the angulation of the tilted implants, angulated abutments of 15º, 25º (ADIN angulated abutment) and Transmucosal angulated abutments of 17º and 33º (ADIN TMA angulated abutments) were placed, respectively, according to the abutment required in each patient.

Prosthesis delivery: Open tray impression coping was placed, and open tray impression was made with addition silicone. Impression was sent to the dental lab for fabrication of prosthesis. Followed by which a cement screw-retained prosthesis was cemented.

Evaluation: A CBCT (cone beam computed tomography) scan of each patient was done after 3 months of prosthesis delivery. The level of crestal bone loss was evaluated in all 20 samples, 10 samples which were loaded with angulated abutments and 10 samples which were loaded with transmucosal abutments.

Observation and Results

In this study, a total of 20 implants were placed in the maxillary arch. Theimplants were randomly allocated in two groups, i.e., Group I where angulated abutments were used, and Group II where transmucosal abutments were used. Within Group I and Group II, 10 samples each were evaluated for crestal bone loss from the mesial, distal, buccal and palatal aspect of the implant site. From the observations that were recorded in the two groups, comparison of crestal bone loss at various sites among the two groups were made. The results of the following observations are mentioned in Table 1.

DISCUSSION

Fixed partial denture was one of the most widely accepted treatment options for rehabilitating partially edentulous patients, but a bridge often requires two healthy teeth to be altered, which, with the advent of implants, is now considered less than ideal for replacing a missing tooth. Dental implants have evolved as a treatment option in which the implant acts as a natural root and the adjacent natural teeth are spared the harmful grinding that is required for a fixed prosthesis. A breakthrough in implant dentistry occurred in the year 1957, when a Swedish orthopaedic surgeon, Per-Ingvar Brånemark, started examining bone healing and regeneration and discovered that bone could effectively grow in proximity to titanium (Ti) and adhere to it without being rejected. This phenomenon was called 'osseo integration' by Brånemark.[4] Since dental implants are placed within the alveolar bone, for successful implant treatment, bone volume has been found to be the single most important governing factor. Ideally, implants should be placed parallel to each other as well as to the adjacent teeth so that the forces can be inclined along the long axis, but in many clinical situations, achieving this may not always be possible. Anatomical variations may make implant placement challenging due to the presence of the maxillary sinus or inferior alveolar nerve; the available bone for implant placement may be very limited.

This is especially true for maxillary bone, often resulting in angulated placement of implants in the maxillary arch, which need to be straightened by the use of angulated abutments so that a prosthesis can be constructed as per the esthetic and functional requirements of the patients. Thus, the present study was conducted on the maxillary arch because implants are more commonly required to be placed in an angulated position in the maxilla as compared to the mandible. Calandriello R and Tomatis M in 2005 conducted a study to propose and evaluate a simplified concept for the rehabilitation of an atrophied maxilla by placement of tilted implants. It was concluded in their study that tilting of implants can be considered a viable option for rehabilitating an atrophied maxillary arch, which provided biomechanically advantageous prosthetic support and also reduced extensive surgically invasive procedures such as ridge augmentation, etc. Hence, they concluded that placing implants in an angulated position may not bring about any negative effect on bone resorption.[5] In a similar study conducted by T. Testori et al, it was concluded that tilting of implants in an atrophic maxilla can result in favourable prosthetic outcomes without carrying out extensive surgical procedures like bone grafting and direct and indirect sinus lift.

However, tilting of the implants necessitates the use of angulated abutments, which causes uneven stress distribution on the restorative crown/bridge as well as the bone since the occlusal forces are not directed along the long axis of the implant. This may result in crestal bone loss, impairing the longevity of the treatment.[6] Lawrence A. Weinberg (1998), in his study on therapeutic biomechanics to reduce implant overloading, stated that every 10° increase in implant inclination causes an average increase of 5% in torque. It was also concluded in his study that cusp inclination is the most potent factor in producing torque, and the torque increases by approximately 15% for every 1 mm of lateral offset. This produces maximum force towards the crestal bone, which may increase the rate of bone resorption, leading to decreased crestal bone levels.[3]Kumari A et al (2020)[20]evaluated stress distribution on

implants in situations with varying distal implant angulations, which showed maximum stress values were always found at the neck of the distal implants, leading to reduced crestal bone levels.[7] The angulation of the tilted implants can be corrected either by using angulated abutments or transmucosal abutments. However, when implants are placed with extensive angulations, the one-piece angulated abutments fail to adequately correct the tilt of such implants, as they are only available in the angulations of 15°, 25° and 35°. In such cases, multi-unit/transmucosal abutments (TMAs) play a crucial role in correcting angulations of implants beyond 35°, ensuring better prosthetic access. Also, the TMA moves the implant's engagement platform from internal to external connection, from the bone level to the soft tissue level, ensuring the benefit of the peri-implant tissue. But limited studies have been reported in the literature that have compared the efficacy of using the transmucosal abutments with that of angulated abutments. Hence, the present study was undertaken to evaluate the crestal bone levels around implants placed in the maxillary arch restored using angulated and transmucosal abutments after 3 months of occlusal function by means of a Cone Beam Computed Tomography (CBCT).

The study was conducted in the Department of Prosthodontics, Santosh Dental College and Hospital, Ghaziabad, for which a total of 20 subjects were selected from the Outpatient Department of the Department of Prosthodontics and Crown & Bridge at Santosh Dental College and Hospital, Ghaziabad. A diagnostic CBCT was made at the first appointment for diagnosis and fabrication of a stent for precise placement of the implant.The implants, measuring more than or equal to 8mm in length and with a diameter of 4.2 mm to 6 mm according to available bone, were positioned at an angle of 10-25 degrees as per the angulation of the available bone by using the surgical guide. In order to correct the angulation of the tilted implants, angulated abutments and angulated transmucosal abutments were used. The subjects were randomly divided into two groups, namely Group I and Group II, which consisted of 10 patients each whose maxillary edentulous arch was rehabilitated by means of implants and the implants were loaded with angulated abutments of 15° angulation and transmucosal abutments of 17° angulation, respectively.

There are two schools of thought, one of which advocates the use of angulated abutments and the other recommends the use of transmucosal abutments. It has been reported that under certain circumstances where implants are not placed in the ideal axial position, use of angulated abutments could result in better stress distribution on the surrounding bone although it is widely accepted that increased stress on crestal bone as well as implants are consistently associated with angulated abutments[8]Numerous studies have been conducted on angulated abutments in the past but current literature is devoid of data regarding the usage of transmucosal abutments. Hence, the current study was conducted using angulated as well as transmucosal abutments in order to give the clinicians a better insight into the positioning of implants and selection of the type of angled abutments so as to decrease crestal bone loss to a greater extent, thus enhancing longevity of the prosthesis. Hernandez-Marcos et al in their study to evaluate the marginal bone loss at the implant level using transmucosal abutments, observed that the use of a transmucosal abutment minimised the crestal bone loss significantly.[9]

P. Cardelli et al.[10] conducted a study in which they observed that the success of implant-supported prosthesis not only depends on osseointegration, but also on biomechanical concepts related to the prosthetic structure assembly when the implants need to be tilted in order to avoid imperative anatomical structures or deficient bone volume and their effects on the bone/implant interface. When the abutment axis angles were 15°, 25°, and 35°, the stress distribution on bone and the prosthetic components was evaluated by means of Finite Element Analysis,in which a 450N maximal biting and 100 N functional force was applied. They concluded that when tilted implants are placed, in order to correct such angulations, the abutments used should not exceed more than 25° in order to avoid excessive bone loss. It was evident from their study that the angulations of the abutments used play an important role in achieving a successful implant supported prosthesis [10]. In a similar study conducted by Reza Tabrizi et al [11], they evaluated the relation between angulated implants and the bone loss around implants in the anterior maxilla. A total of 58 patients were subjected to delayed-loading on angulated implants, and it was observed that the mean implant angulation was 15.2° and the mean resorption was 0.87mm. Hence, they concluded that the implant angulation did not change bone resorption and it can be used as an alternative to vertical implants to avoid the grafting procedure.

Clinically, it is nearly impossible to accurately appreciate and quantify crestal bone levels in the patient's mouth, but it can be well-measured radio graphically. In the present study, radiovisiography (RVG) and Cone Beam Computed Tomography (CBCT) have been used for determining the amount of crestal bone loss post-loading. RVG has been used commonly and is considered a feasible as well as a cost-effective technique for implant imaging with minimum discomfort and minimal radiation exposure to the patient. But the main disadvantage of RVG is that it can produce radiographic images only in a single plane, i.e., only two-dimensional images can be obtained, which cannot be used to accurately determine the crestal bone levels. On the other hand, a CBCT can produce three-dimensional radiographic images of the patient's maxilla. It allows visualization without superimposition, and the ability to view the concerned structures from different angles using a CBCT helps to evaluate the architecture and dimensions of the bone more accurately.[12] In this study, for the purpose of standardisation, radiovisiographic (RVG) images were taken with the help of an RVG sensor holder and a customised bite index to evaluate the level of crestal bone on the day of the placement of the implants for all 20 samples. Subsequently, all 20 samples were loaded either with angulated abutments or transmucosal abutments. A Cone Beam Computed Tomography (CBCT) scan of each patient was done 3 months after prosthesis delivery in order to accurately measure the crestal bone loss in each case. The alveolar bone height around the neck of the implant has always been considered an important parameter in the success of implant-supported prosthesis treatment. In general cases, periapical radiographic images (e.g., RVG) can produce information about the crestal bone levels towards the mesial and distal aspect of the implant site; however, these images are incapable of providing information regarding the crestal bone level on the buccal and palatal aspect around the implant.

In such conditions, a CBCT scan becomes an extremely useful tool which makes it possible to observe the crestal bone loss from all the aspects of the implant site, i.e., mesial, distal, buccal, and palatal.[12] In the present study, it was observed from the CBCTs obtained that the mean bone loss mesially in group I was 1.280± 0.316 and in group II was 1.401 ± 0.256, whereas distally it was observed that crestal bone loss was 1.200 ± 0.346 in group I and 1.388 ± 0.191 in group II, respectively. Observations made for group I from the buccal site were 1.320 ± 0.312, and in group II it was observed 1.298 ± 0. 129. From the palatal aspect, the readings observed for group I were 0.990 ± 0.191 and for group II were 1.289 ± 0. 258. From the results obtained in the present study, it can be suggested that there is not much difference in the crestal bone loss when implants are placed in a tilted position, whether they are loaded with angulated abutments or transmucosal abutments. As the results obtained in our study failed to reach the level of significance, further long-term in-vitro and in vivo studies comparing the efficiency of angulated abutments and transmucosal abutments with respect to crestal bone loss, stress distribution as well as soft tissue profile are required. In another study [13], it was concluded that dental implants with angulated abutments exhibited higher von Mises stress in the peri-implant bone than those restored with straight abutments under both axial and oblique loads, while the dental implants restored with zirconia straight and angulated abutments transferred less stress to the peri-implant bone than those with titanium abutments. Therefore, within the limitations of the present study, it can be concluded that angulated abutments as well as transmucosal abutments can be helpful in correcting the angulation of the tilted implants without affecting the rate of crestal bone loss when compared to placement of axial implants. However, it is not only the angulation of the abutment but also the material that has to be taken in account. Besides, three months is too short a period, more long term clinical studies are required to further conclude.

ABSTRACT

Covid-19 upsurge in 2019 trembled the entire world and left the whole medical fraternity grappling to know, comprehend and get to the bottom of its complex character. With a huge death toll the SARS-CoV-2 pandemic shattered personal and professional lives everywhere. Apart from other symptoms a number of Covid positive patients had also complained of oral lesions. The present study thus aimed at assessing the prevalence of oral symptoms among Covid-19 infected patients. To assess the oral manifestations amongst the admitted Covid–19 infected adult patients in a Hospital in Delhi. As the poor oral health may impact the Covid-19 severity we also analysed the oral hygiene behaviour and self reported health risk behaviour amongst the infected patients. A questionnaire based pilot observational study was conducted on patients admitted in a Hospital in Delhi, who were positive to coronavirus and presented varied oral manifestations. Assessment of oral health among COVID-19 infected patients was done by asking questions regarding the oral hygiene measures taken. Also Information on self reported health risk behaviour was collected and assessed. A total of 89 adult patients, 61 males and 28 females who were positive for coronavirus were assessed for oral manifestations from May 2021 to July 2021. Our results showed that 61.7% of the patients had at least one oral manifestation and depapillation of tongue (52.8 %) was the highest prevalent symptom followed by dry mouth (39.3%), burning sensation (17.9%). The less prevalent symptoms were erythematous mucosa (7.8%) and ulcers (5.1%). However, there was no significant association between the incidence of oral symptoms and demographic data of the patients

($p > 0.05$). With the limited data available we could conclude that COVID-19 significantly impacts the oral cavity. However, a more substantial research project is required to address this relation.

Keywords: Oral manifestations, COVID-19, Health risk behaviour, Oral health, Systemic diseases, Post-COVID complications, Mucosal lesions

INTRODUCTION

Although this study was conducted during the second wave of the COVID-19 pandemic in 2021, its findings remain highly relevant even today. Periodic resurgences of COVID-19, including emerging variants, continue to pose a public health concern worldwide. Moreover, long-term and delayed post-COVID complications—commonly referred to as "long COVID"—are now being recognized more comprehensively, with oral manifestations increasingly reported among these cases. The observed oral lesions, such as depapillation, dry mouth, and mucosal irritation, may not be limited to the acute phase of infection but could also represent persistent or delayed effects resulting from immune dysregulation, prolonged medication use, or viral-induced tissue damage. Thus, the oral cavity may serve not only as a site of early manifestation during active infection but also as a window into the systemic after-effects of COVID-19, especially in patients with comorbidities and poor oral hygiene behavior. As we progress into the post-pandemic phase, a growing body of literature is now exploring oral sequelae in recovered patients, reinforcing the hypothesis that oral health monitoring should be an integral part of both acute management and long-term follow-up in COVID-19 cases. This study provides foundational data that can aid future research in identifying patterns, risk factors, and prognostic indicators associated with oral manifestations of viral illnesses, especially COVID-19 and its evolving variants. It also highlights the need to incorporate dental professionals in multidisciplinary teams managing post-COVID care, emphasizing the interplay between systemic and oral health.

Wuhan Pneumonia of unknown origin,a novel coronavirus under the seventh member of the coronavirus family, was first identified by Chinese researchers through sequencing its genome. On 30th January 2020 WHO (the World Health Organization) declared this outbreak as a Public Health Emergency of International concern (PHEIC) due to its spread across more than 18 countries as of today. WHO gave it the name of Covid - 19, short for coronavirus disease 2019. The appearance in December 2019 of this new coronavirus caused an unprecedented pandemic in the modern era. Undoubtedly, this disease produced by the novel coronavirus and its consequences have posed a challenge for health authorities worldwide. The way of contagion through direct contact and through saliva in the form of small drops and the production of aerosols have facilitated the rapid spread worldwide [1]. Covid - 19, a respiratory illness caused by SARS-CoV-2, emerged rapidly at the end of 2019. The novel lethal strain of coronavirus was the major causal agent of a global pandemic burden, affecting millions of people across the globe, having life threatening outcomes not only in immune compromised and medically compromised individuals, but also in seemingly healthy young individuals as well[1]. With the rapid rising death toll, it was classified as a global pandemic by WHO (World Health Organization), and along with it's rapid increase in incidence, the illness' effects on various parts of the human body were slowly observed and analysed.

But even with the new declaration of the end of Covid-19 being a global health emergency in 2023, the effects of the illness linger, and the burden left behind affecting hundreds of thousands of individuals remains ever so abundant. Symptoms of the illness had a vast range, typically from fevers, fatigue, dry cough and dyspnea to runny nose and other upper respiratory symptoms. Some atypical symptoms included but not limited to gastrointestinal symptoms such as nausea, diarrhoea, vomiting, loss of smell - also known as Anosmia - or loss of taste - known as Aguesia - and more. Apart from the respiratory and gastrointestinal symptoms, many Covid- positive patients also had complaints of oral lesions attributing to Covid-19[2]. It is a common known fact that overall health has an acute relation to oral mucosal lesions. Many systemic and local diseases show specific and/or unspecific lesional changes that may evolve during the course of the disease, including varying levels of mucosal reactions constituting the initial clinical signs of

the disease. The oral cavity is a multi-functional site for ingestion of food, starting the process of digestion, for taste perception and articulation. It also provides protective properties against various toxic agents like microorganisms, trauma etc. Various factors intricately interact within each other like the structure of the oral mucosa and its interaction with saliva to facilitate the same[3].

The oral mucosa has an intimate contact with and interrelates with many general systems of the body. Healing of the oral mucosa is facilitated primarily by the excellent blood supply and its association with the immunologic system. The contents of immunologically competent cells contribute to the body's defence mechanism against exogenous "non-self, bioactive or other chemical" agents. The mucosa also contains various neurologic structures having varying functions ranging from propagating the sense of taste to also contributing to proprioception. Due to all the different aspects mentioned, different parts of the oral mucosa have different properties and thus accordingly show different macro and micro characteristics, due to which the categorisation of mucosa into several classes of tissues is justified. Like the thin non-keratinized lining mucosa of the floor of the mouth does not have much in common with the tough keratinized mucosa of the hard palate, while the gingiva propria or the mucosa of the dorsal aspect of tongue all are different from each other [3,4,5].

With that mentioned, it is logical to concur that the oral mucosa is definitely affected by the impairment of general overall health, secondly that the manifestations of general illness may be liable to affect various aspects of the mucosa and that these said manifestations may look different for different parts of the oral mucosa. It can also be said that the opposite - diseases in various parts of the oral mucosa affecting general health - may also be true[4,5,6,7]. So keeping that in mind, it is logical that Covid-19 will have various types of oral manifestations. Knowing them and keeping track of them aims to make early detection and decrease in future incidences of the illness possible.

MATERIAL AND METHODS

Background of Respondents

Respondents in this study were patients testing positive for Covid- 19 admitted in a hospital in Delhi, and were presenting with varied oral manifestations.

Study population and setting

This questionnaire based study was conducted in a period of May 2021 to July 2021. A total of 89 patients took part. Patients of varying ages (from 18 to 80 years) and gender were asked to respond anonymously to a questionnaire regarding the general oral health of the patient, the various oral manifestations and types of management done for the same. Before the study was conducted, the questionnaire was reviewed by all authors and validated to verify clarity and reliability.

Inclusion criteria:

- Patients in the age group of 18 years to 80 years were included.
- Patients from both genders infected with SARS - CoV 2 virus, diagnosed with a real time polymerase chain reaction test.
- Mild to moderate hospitalised Covid-19 positive cases willing to participate in the study.
- Patients not inflicted with oral manifestations prior to the pandemic and subsequent infection.

Exclusion criteria:

- Patients younger than 18 years and older than 80 years were excluded.
- Patients unwilling to give consent were excluded.
- Patients with severe Covid - 19 infection requiring intensive care
- Patients suffering with severe pneumonia dyspnoea, respiratory rate > 30 breaths/min, oxygen saturation < 90% at the time of data collection.

Data collection tool

Questionnaire Development:

The questionnaire that is developed consists of 7 questions excluding demographic information and was based on a comprehensive literature review and consultation with experts. It was designed to assess: Mode of diagnosis, oxygen requirement, intake of steroids with their mode and duration.

- In terms of blood parameters; Crp, ferritin, LDH, D-Dimer, IL-6
- In terms of Oral manifestations Taste and clinical appearance is assessed.
- Symptomatic prevalence of fever, dry cough, sore throat, diarrhoea, bodyache, loss of smell, loss of taste, fatigue, dizziness, shortness of breath were also assessed.
- All the sites associated with the lesion were also assessed.
- Health risk behaviour amongst smokers, tobacco users, heavy drinkers, hypertensive, diabetic etc was also analysed amongst the infected patients.

The questionnaire was distributed in paper format to maximize response rates. Participants were informed about the purpose of the study, and their consent was obtained prior to participation. The survey includes demographic questions, multiple-choice questions and open-ended questions to capture both quantitative and qualitative data.

The study was divided in 5 sections , namely;

- Section 1: Demographic details (age, gender) and COVID-19 specific diagnostic and treatment information (mode of diagnosis, oxygen and steroids requirement)
- Section 2: included questions about the most commonly reported COVID-19 symptoms the patients suffered from.
- Section 3: contained questions regarding the oral hygiene measures taken while being infected with COVID-19
- Section 4: Information on self reported health risk behaviour [Modifiable-tobacco, alcohol consumption, physical fitness and Metabolic- Non Communicable Diseases]
- Section 5: questionnaire containing multiple manifestations that were to be associated with COVID- 19 based on the available evidence.

Among the 89 COVID-19 patients analyzed for oral manifestations and health risk behavior, 61 (68.5%) were male, and 28 (31.4%) were female. Age distribution showed that 17 (19.1%) were under 30 years (Group 1), the majority, 48 (53.9%), were between 31-60 years (Group 2), and 24 (26.9%) were over 60 years (Group 3). Among 89 COVID-19 patients surveyed, RT-PCR was the most common diagnostic method (67.4%), followed by Rapid Antigen tests (16.8%) and HRCT (15.7%). Oxygen therapy was required by 67.4% of patients. Steroid use was reported by 83.1%, with administration via oral (46.06%), IV (29.2%), and inhaled routes (7.86%). Most patients (58.4%) received steroids for less than two weeks, while 24.7% had prolonged use exceeding two weeks Among COVID-19 patients, the most common symptoms were loss of taste (68.5%), body aches (67.4%), fever (65.1%), and loss of smell (58.4%). Other frequently reported symptoms included dry cough (55.05%), sore throat (51.2%), and fatigue (49.2%). Less prevalent symptoms were dizziness (37.07%), diarrhoea (30.3%), and shortness of breath (11.3%), the least reported. The findings highlight the varied symptom experiences among patients, with sensory and musculoskeletal symptoms being the most prevalent.

The statistical analysis of health risk behaviors among COVID-19 patients (n=89) revealed significant associations with several modifiable and metabolic risk factors. Smoking (39.3%), tobacco use (15.7%), and heavy drinking (13.4%) were significantly correlated with COVID-19 severity ($p < 0.05$). Among metabolic conditions, hypertension (23.5%), diabetes (16.8%), cardiovascular disease (11.2%), and chronic respiratory conditions (12.3%) showed strong associations with infection outcomes ($p < 0.001$). Physical inactivity (55.05%) did not show a significant correlation ($p = 0.34$). These findings emphasize the need to address modifiable risk factors and manage pre-existing conditions to reduce COVID-19 complications. The statistical analysis of oral manifestations and demographic factors showed that 65.9% of males and 63.4% of females experienced symptoms, with age playing a more significant role than gender. Group 1 had the highest prevalence (70%), while Groups 2 and 3 had 62% and 52.6%, respectively ($p = 0.04$).

Discoloration of the tongue (52.8%) was significantly associated with age (p = 0.01), whereas dry mouth (39.3%), burning sensation (17.9%), and ulcers (5.6%) showed no significant gender or age differences. Halitosis (16.8%) approached statistical significance for gender (p = 0.07). Overall, age appears to be a stronger predictor of oral manifestations than gender.

DISCUSSION

This study has aimed to highlight the significant impact that COVID-19 previously had and currently has on oral health by examining the prevalence of oral manifestations among various infected patients. Out of the total sample size, 61.7% are exhibiting at least one oral symptom, and hence it is evident that the SARS-CoV-2 virus affects the oral cavity either directly or through secondary mechanisms such as immune dysregulation, medication side effects, or systemic inflammatory responses among more[8,9]. The most commonly reported oral symptom was depapillation of the tongue (52.8%), followed by dry mouth (39.3%) and burning sensations (17.9%). Less common manifestations included erythematous mucosa (7.8%) and ulcers (5.1%). These findings are consistent with previous research suggesting that COVID-19 is associated with a range of oral manifestations, which could serve as potential early indicators of infection[10,11]. With the high prevalence of depapillation of the tongue it is evident that COVID-19 has the potential to cause alterations in epithelial cell turnover and mucosal immunity. Depapillation has been linked to various deficiencies in essential nutrients such as vitamin B12, iron, and folic acid—conditions that may arise in COVID-19 patients due to dietary changes, gastrointestinal symptoms, or systemic inflammation[12]. Additionally, direct viral interactions with angiotensin-converting enzyme 2 (ACE2) receptors in the oral mucosa could contribute to epithelial cell damage and subsequent loss of lingual papillae. The role of ACE2 receptors in COVID-19 pathology has been extensively studied, with evidence suggesting that the oral cavity, particularly the tongue, serves as a reservoir for viral entry and replication [12].

The high prevalence of dry mouth (39.3%) in our study aligns with other reports linking COVID-19 to xerostomia. The etiology of dry mouth in infected patients is likely multi factorial, involving direct viral infiltration into salivary glands, immune-mediated destruction of glandular tissue, and medication-induced effects, particularly in those receiving oxygen therapy and corticosteroids [13]. The reduction in saliva production is concerning as it compromises oral homeostasis, increasing susceptibility to secondary bacterial infections, dental caries, and periodontal disease. Further investigation is needed to determine whether these salivary alterations persist post-recovery and contribute to long-term oral health complications [14]. A notable 17.9% of participants reported a burning sensation, a symptom frequently associated with viral infections, mucosal inflammation, and altered taste perception. This could be due to inflammatory cytokine release, neuropathic involvement, or altered salivary composition [15]. Previous studies have linked burning mouth syndrome to dysregulation of sensory nerve fibers, and COVID-19 may exacerbate this condition through neuroinvasive mechanisms. Since SARS-CoV-2 has demonstrated neurotropic properties, affecting the olfactory and gustatory pathways, the presence of burning sensations warrants further neurophysiological studies to determine the extent of viral involvement in peripheral nerve dysfunction [15]. Interestingly, ulcers and erythematous mucosa were observed in a smaller percentage of patients (5.1% and 7.8%, respectively). While the occurrence is lower than other symptoms, these lesions may indicate more severe local immune dysregulation or secondary infections such as viral, bacterial, or fungal co-infections. Stress-related factors, including increased corticosteroid use and systemic inflammation, may also contribute to ulcer formation. These findings align with previous studies suggesting that ulcerative lesions in COVID-19 patients may result from thrombotic vasculopathy, hypercoagulability, and endothelial dysfunction, which have been widely reported in severe cases of the disease [16].

An important aspect of our study was the assessment of the relationship between oral manifestations and pre-existing health risk behaviors. Our findings demonstrate significant associations between COVID-19 outcomes and modifiable risk factors such as smoking (39.3%), tobacco use (15.7%), and heavy alcohol consumption (13.4%), as well as metabolic conditions including hypertension (23.5%), diabetes (16.8%), cardiovascular disease (11.2%), and chronic

respiratory conditions (12.3%). These comorbidities are well-documented risk factors for severe COVID-19 outcomes, and their association with oral health deterioration in infected patients is an area that requires deeper investigation [17]. Smoking and tobacco use significantly impair immune function and increase susceptibility to viral infections. Nicotine and other toxic substances in tobacco reduce salivary flow, compromise the integrity of the oral mucosa, and impair immune surveillance, making smokers more prone to developing oral lesions [18]. Furthermore, smoking has been linked to increased ACE2 receptor expression, potentially facilitating viral entry and replication in the oral cavity. The correlation between smoking and COVID-19 severity underscores the need for targeted public health interventions to address this risk factor in post-pandemic oral health management.

Similarly, diabetes and hypertension have been identified as significant risk factors for severe COVID-19, and our study highlights their potential impact on oral health. Diabetes has long been associated with delayed wound healing, increased susceptibility to infections, and oral complications such as periodontitis and xerostomia[19]. COVID-19-induced systemic inflammation may further exacerbate these conditions, leading to more severe oral manifestations. Hypertension, often linked to vascular dysfunction, may also contribute to oral mucosal changes through impaired microcirculation and increased susceptibility to ischemic damage. Another significant finding was the high prevalence of oxygen therapy (67.4%) and steroid use (83.1%) among patients. Prolonged oxygen therapy can lead to mucosal dehydration, contributing to dry mouth and mucosal irritation. Similarly, corticosteroid use is known to cause immune suppression, increasing the risk of oral candidiasis and secondary infections. In our study, patients receiving steroid therapy for more than two weeks (24.7%) were more likely to report oral manifestations, reinforcing the need for cautious use of steroids and regular oral health monitoring in hospitalized COVID-19 patients[20,21].

While our study provides valuable insights into the oral manifestations of COVID-19, certain limitations must be acknowledged. The sample size (n=89) is relatively small, limiting the generalizability of the findings. Additionally, the reliance on self-reported data introduces potential recall bias and subjectivity in symptom reporting. A more comprehensive study with a larger, more diverse population and objective clinical assessments, including oral examinations and salivary biomarker analyses, would provide a more accurate understanding of the impact of COVID-19 on oral health. Future research should explore the long-term effects of COVID-19 on oral health, particularly whether oral manifestations persist in post-acute sequelae of COVID-19 (long COVID) patients. Longitudinal studies tracking changes in oral health over time, coupled with investigations into potential mechanisms such as cytokine-induced inflammatory responses, viral persistence, and endothelial dysfunction, would further enhance our understanding. Moreover, exploring potential interventions such as targeted oral hygiene protocols, salivary diagnostics, and nutritional support could aid in the prevention and management of oral complications associated with COVID-19.

Conclusion

The findings of this study emphasizes the importance of oral health pertaining to COVID-19. It was observed that a significant proportion of infected patients experienced oral manifestations, with depapillation of the tongue, dry mouth, and burning sensations being the most prevalent symptoms seen. These symptoms are likely influenced by systemic inflammatory responses, immune dysregulation, medication effects, and other pre-existing health conditions like diabetes etc. Our study also highlights modifiable health risk behaviors such as smoking, tobacco use, and heavy drinking, which may have a role in exacerbating the oral complications present in COVID-19 patients. Given the systemic nature of COVID-19 and its multi-organ involvement, oral health should not be overlooked in disease management. Dental professionals should play an active role in the multidisciplinary management of COVID-19 patients, focusing on early detection, preventive measures, and post-recovery oral health care. Integrating routine oral health assessments into COVID-19 treatment protocols may improve patient outcomes and contribute to overall well-being. Moving forward, larger-scale studies and clinical trials are essential to further investigate the complex interplay between COVID-19 and oral health. Understanding these relationships could pave the way for targeted interventions that not only mitigate oral complications but also improve overall disease prognosis and quality of life for affected individuals.

ABSTRACT

Renewable energy comes from natural sources that can be replenished faster than they are consumed. Globally, renewable energy sources now make up 29% of current electricity production. Renewable energy sources produce little to no greenhouse gas emissions. A quasi-experimental one-group pretest–posttest design was adopted for the study. A multistage simple random sampling technique was used to select 104 households. The pretest data were collected using a structured interview questionnaire. Following the pretest, the researchers provided an interactive teaching session on renewable energy using a pamphlet for 15–20 minutes. Seven days after the intervention, the posttest was conducted using the same structured interview questionnaire. Results shows that in pre test highest 75 (72.1%) households were having moderate level of knowledge on renewable energy sources whereas in post test 87 (83.7%) had high level of knowledge and none had low level of knowledge on renewable energy sources. Pretest and posttest knowledge mean and SD was 15.26 + 2.780 and 20.07 + 2.122 respectively. The calculated Wilcoxon signed rank test value was Z = - 8.437 p value is less than 0.001 was found to be highly significant. There was no significant association found between the level of knowledge on renewable energy source with any of the socio demographic variable at $p<0.05$. The study concluded that interactive teaching session enhanced the participants' awareness and understanding on renewable energy

resources. Therefore, it can be considered an effective educational strategy for promoting awareness of renewable energy sources among households.

Keywords: Renewable energy sources, Interactive session, Awareness and Households

INTRODUCTION

The most important need of human in every activity of daily life is energy. There are different forms of energy resources on earth. All energy sources have some impact on our environment, and the environmental impact of energy sources has a diverse origin. [1] Non-renewable energy comes from sources that cannot be replenished in our lifetime. The most common sources of non-renewable energy are carbon-containing fossil fuels, including coal, petroleum, and natural gas. Burning such fossil fuels generates many pollutants like carbon dioxide, which are the prime reason for global warming condition. [2] Fossil fuels are the largest contributor to global climate change, accounting for over 75 percent of global greenhouse gas emissions and nearly 90 percent of all carbon dioxide emissions. [3] The widespread and uncontrolled use of fossil fuels during the industrial revolution produced irreparable environmental impacts. [2] Renewable energy comes from natural sources that can be replenished faster than they are consumed. Globally, renewable energy sources now make up 29% of current electricity production. [3] It is the key element of sustainable, environment friendly and cost effective source of energy. Currently used renewable energy sources worldwide are solar energy, hydro energy, wind energy, bio energy geothermal energy and hydrogen energy. [4] The United Nations says that with technology available today, cheap electricity from renewable sources could provide 65 percent of the world's total electricity supply by 2030 and decarbonize 90 percent of the power sector by 2050, massively cutting carbon emissions and improving air quality. [3]

Globally, there is a growing recognition of the need to transition towards renewable energy to achieve energy security and reduce carbon emissions. International agreements like the Paris Agreement underscore the commitment of nations to limit global temperature rise by promoting renewable energy adoption. In India, the government has set ambitious targets for renewable energy capacity expansion, aiming to achieve 175 gigawatts (GW) of renewable power capacity by 2022 and 450 GW by 2030. Policies such as the National Solar Mission and incentives for wind energy development are pivotal in driving this transition. [5] According to comprehensive study report by Auroville consulting, Puducherry can meet more than 60% of its electricity demand from renewable energy by 2030. Currently, renewable energy contributes only 19% of Puducherry's total electricity supply, including power purchased from other States. [6] The Puducherry Electricity department, in association with the Renewable Energy Agency, organised a camp to propagate awareness on the benefits of installing rooftop solar photo voltaic plants in residential households and informed the public about the Government of India subsidy to the tune of ₹30,000 for 1 KW, ₹60,000 for 2 KW and ₹78,000 for 3 KW to residential consumers. So far, 2,342 consumers have commissioned rooftop solar plants and an estimated ₹16.24 crore has been disbursed as subsidy. [7] Despite the global and national push towards renewable energy adoption, many communities, including those in Puducherry, still lack adequate understanding of these technologies. This knowledge deficit often leads to misconceptions about feasibility, costs, and benefits associated with renewable energy sources such as solar, wind, and biomass

At the community level, awareness and participation are crucial for the successful adoption of renewable energy technologies. While initiatives like rooftop solar installations have gained traction, there remains a need to increase awareness and understanding among households across different socio-economic backgrounds. Empowering communities through interactive session bridge knowledge gaps, inspire adoption profound and can have socio-economic impacts. When households gain knowledge about renewable energy technologies, they are better equipped to make informed decisions regarding energy consumption and management. This empowerment extends beyond mere awareness to practical considerations such as cost savings through energy efficiency measures and potential income generation from renewable energy investments. By addressing the existing knowledge gaps on renewable

energy sources this study directly contributes to United Nations Sustainable Development Goals (SDGs) specifically SDG 03 (Good health) SDG 7 (Affordable and Clean Energy) and SDG 11 (Sustainable Cities and Communities) at the local level and further these findings support the Puducherry Government's initiatives on renewable energy.

MATERIALS AND METHODS

Research Design: Quasi Experimental - one group pretest and posttest design was used to assess the effect of interactive session regarding the renewable energy sources among households in selected community, Puducherry.

Setting of the Study: Alankuppam rural area comprised of 5349 population which is situated right next to the international township of Auroville. Administered by Olagaret Municipality, Puducherry. This village includes Annai Nagar, G.V Nagar, Indira Nagar, Sanjeevi Nagar, Pudhu Nagar and Motherland

Sample size: Assuming pre test mean and standard deviation 3.73 and 0.59 based on previous study [8] , effect size of 0.36 , power of 90% , significance level 5%, sample size required for the study is 82 with 10% attrition, sample size was increased to 92 and the study completed with 104 participants.

Sampling technique and criteria: Multistage random sampling technique was adopted for the study. In the first stage, three areas (Sanjeevi Nagar, Annai Nagar and G.V Nagar) were selected by lottery method. In the second stage, three streets were randomly selected from each area. In the third stage, Systematic random sampling was used to select 104 households across nine streets by choosing every second households.

Sampling criteria

Inclusion criteria: Adults who are

- Permanent resident of Alankuppam
- Members of household between 20-60 years of age.
- Members of household who can understand Tamil.

Exclusion Criteria: Adults who are

- Mentally challenged,deaf and dumb
- Migrants residing in Alankuppam

Instruments and tools

Section A: Proforma to elicit Demographic characteristics such as Age, Gender, Education Occupation, Monthly family income [9], Religion, Type of family, Previous knowledge about renewable energy, source of information and use of renewable energy, and reason for using and not using it.

Section B: Structured Interview Questionnaire to assess the effect of interactive session regarding the renewable energy sources. There were 25 questions with Yes and No options of which 10 questions where negative and 15 questions were positive.

Ethical Consideration: The proposed study was conducted after approval of research committee. The researchers obtained formal permission from the concerned Medical Officer of Health and Wellness Centre, Puducherry. Informed consent was obtained from the adults who fulfill the inclusion criteria after explaining the study purpose.

Validity and Reliability: The content validity of the tool was established by the five experts from Community Health Nursing Department, Environmental Engineering, Community Medicine, Bio statistics and Social worker. The tool was modified as per suggestions and recommendations of the experts. Reliability of the knowledge questionnaire was established by Split half method, where the Spearman Brown Prophecy rho=0.9. The internal consistency of tool was found to be reliable

Data Collection Plan

Pretest data was collected for two days from 2 July 2024 to 3 July 2024 spending 10-15 minutes to each study participants using structured interview questionnaire. Following the pretest, the researchers provided an interactive teaching session on renewable energy using a pamphlet for 15 to 20 minutes. After seven days Posttest data was collected for two days from 9 July 2024 to 10 July 2024 spending 10-15 minutes to the same study participants using the same structured interview questionnaire. Collected data was checked for its correctness and completeness at the end of each day.

Data Analysis plan

Data were entered in Microsoft excel sheet and analyzed using version 2.0 SPSS software. Descriptive statistics, including Frequency, Mean, Percentage and standard deviations were used to summarize Socio demographic variables and level of knowledge regarding Renewable energy sources among households. Inferential statistics, including Chi-square test used to evaluate the association between knowledge levels regarding renewable energy sources and demographic variable of households and Wilcoxon signed rank test used to assess the effect of interactive session by comparing pre- and post-intervention knowledge scores on renewable energy sources households.

RESULTS

Description of Socio-demographic variables of households

Table 1a and 1b shows that 55 (52.9%) of them were in age group of 20-40 years, 78 (75%) of them were female, 26 (25%) were having Primary School certificate, 55 (52.9%) of them were unemployed. Most of the them100 (96.2%) were Hindu and 79 (76%) of them were living in nuclear family, 40 (38.5%) had monthly family income of Rs. 7,316-21,913, 58 (55.8%) of them were not having knowledge about renewable energy sources.

Utilization of Renewable Energy Sources

Fig 1 shows that 91 (87.5%) were not using renewable energy source and the reason found were lack of awareness about renewable energy sources, high installation costs. 13 (12.5%) were using solar energy in addition to conventional energy and the reason found was it lowers electricity bill.

Level of knowledge on renewable energy sources among households

Table 2 shows that in pre test highest 75 (72.1%) households were having moderate level of knowledge on renewable energy sources whereas in post test 87 (83.7%) had high level of knowledge and none had low level of knowledge on renewable energy sources.

Distribution of level of knowledge among households based on the aspects of renewable energy sources.

Table 3 shows that in pre test 37 (35.5%) of them had high level of knowledge whereas in Post test 90 (86.5%) had high level of knowledge on energy and conventional energy. Only six had high level of knowledge in Pretest, whereas in Post test 58 (55.7%) had high level of knowledge about types of Renewable energy. Regarding Benefits of renewable energy 54 (51.9%) had high level of knowledge in Pretest, whereas 86 (82.6%) had high level of knowledge in Post test.

Effect of interactive session on level of knowledge regarding renewable energy sources among households

Table 4 shows that Pretest and posttest knowledge mean score and SD was 15.26 $\pm$ 2.780 and 20.07 $\pm$2.122 respectively. The calculated Wilcoxon signed rank test value was Z = - 8.437 found to be highly significant at p value is less than 0.001.

Mean & SD of Pre & Posttest level of knowledge based on the aspects of renewable energy sources among households

Table 5 shows that pretest and posttest knowledge mean & SD was 3.94 ± 1.221 and 5.45 ± 0.823 in the area of renewable and conventional energy. Regards with types renewable energy Mean and SD was 5.82 ± 1.705 in pretest whereas in posttest 8.66 ± 1.485. Mean & SD of Knowledge on Benefits of renewable energy was 5.50 ± 1.526 and 6.59 ± 1.058 in pretest and posttest respectively. It interprets that there is increase in the mean knowledge score during posttest and thus it proves the effect of interactive session on renewable energy.

Association between the Level of knowledge on renewable energy sources and socio-demographic variable among households

Table 6a and 6b shows that there was no significant association found between the level of knowledge on renewable energy source with the socio demographic variable such as age, gender, education, occupation, religion, type of family , monthly family income , previous knowledge about renewable energy source , source of information and use of renewable energy source .

DISCUSSION

In pre test highest 72.1% households were having moderate level of knowledge on renewable energy sources whereas in post test 83.7% had high level of knowledge and none had low level of knowledge on renewable energy sources. It shows that interactive session was effective (Table 2). Study finding were supported by Md. Kamrul at.al, who observed that the majority of the respondents answers fell between low and medium, and only a small percentage of respondents demonstrated high level of knowledge on different types of renewable energy resources which is controversial to our study findings. [10] The study shows that pretest and posttest knowledge mean and SD was 15.26 ± 2.780 and 20.07 ±2.122 respectively. The calculated Wilcoxon signed rank test value was Z = - 8.437 p value is less than 0.001 was found to be highly significant. Hence the stated research hypothesis (H_1) was accepted and concludes that there was significant improvement in the knowledge level among households after interactive session. It shows that use of a pamphlet, along with the interactive teaching session enhanced the participants' awareness and understanding on renewable energy resources. Therefore, interactive teaching supported by informational pamphlets can be considered an effective educational strategy for improving knowledge and promoting awareness of renewable energy sources among households. (Table4). Leomar Sabroso et.al (2024) reported Household awareness on renewable energy, Mean 3.73 and Standard deviation 0.59. The calculated Z= 2.33 and p value is equal to 0.02 was found to be significant. [11]

Limitations

Sample size limits the generalization of findings. Understanding about various Renewable energy source among households was limited and thus researchers had difficulty in familiarizing the term in Tamil while data collection.

CONCLUSION

The study concluded that, the interactive teaching session using a pamphlet enhanced the participants' awareness and understanding on renewable energy resources. Therefore, interactive teaching supported by informational pamphlets can be considered an effective educational strategy for improving knowledge and promoting awareness of renewable energy sources among households.

ABSTRACT

This research examines the blood pressure patterns of 50 participants using clustering techniques such as Fuzzy C-Means (FCM), Possibilistic C-Means (PCM), and Possibilistic Fuzzy C-Means (PFCM). Participants were categorized into low, normal, and high blood pressure groups based on their systolic and diastolic readings. FCM was adept at identifying overlapping cases, particularly those individuals whose blood pressure was on the borderline between categories. PCM focused on absolute membership, minimizing the influence of outliers and resulting in a more compact cluster structure. PFCM integrated both fuzzy and possibilistic memberships, delivering a robust and detailed clustering approach that effectively pinpointed borderline and high-risk individuals. A comparative analysis of the three methods showed that PFCM offered the most thorough understanding of blood pressure patterns, balancing cluster overlap with absolute certainty. The findings also indicated trends across different age and departmental groups, with older individuals more frequently exhibiting higher blood pressure readings. In summary, this study demonstrates the utility of fuzzy and possibilistic clustering methods in analysing health-related data and identifying individuals who may need monitoring or intervention.

Keywords: Blood Pressure Analysis, Fuzzy C-Means (FCM), Possibilistic C-Means (PCM), Possibilistic Fuzzy C-Means (PFCM), Fuzzy Clustering,

Mathematics Subject Classification (2020): 03E72, 62H30

INTRODUCTION

Blood pressure serves as a key physiological marker crucial for evaluating cardiovascular health. Identifying abnormal blood pressure levels, such as hypertension or hypotension, early on is vital to avert serious health issues. Traditional methods for classification typically use fixed thresholds to sort individuals into categories of low, normal, or high blood pressure. However, these rigid boundaries fall short when dealing with borderline or uncertain cases, where readings may hover near category limits [11,6]. To overcome this shortcoming, fuzzy clustering techniques have gained traction in medical and health data analysis. The Fuzzy C-Means (FCM) algorithm is widely adopted, allowing data points to belong to multiple clusters with varying membership degrees, thus effectively addressing overlaps and uncertainties in datasets [3,6,9]. FCM has been applied successfully in various health data analyses, including cardiovascular risk assessment and biomedical signal clustering [10,12]. Nonetheless, FCM is prone to outliers because it depends on relative membership, which can distort cluster centers [3,9]. Possibilistic C-Means (PCM) mitigates this issue by emphasizing absolute membership values, thereby reducing outlier influence and forming more compact clusters [9,11]. PCM offers a more robust representation for individuals with unusual readings but might undervalue relationships between points in overlapping areas [6,11]. Possibilistic Fuzzy C-Means (PFCM) merges the advantages of FCM and PCM, balancing fuzzy and absolute membership, thus effectively capturing both borderline and high-confidence cluster assignments [1,2,5,11]. Recent developments in PFCM, including suppression-based and feature-weighted versions, have further improved clustering accuracy in complex datasets [2,4,11]. Clustering methods like FCM, PCM, and PFCM have shown potential in medical applications, such as disease subgroup discovery, patient stratification, and predictive health monitoring [5,7,8,10,12]. These techniques are particularly beneficial for datasets like blood pressure readings, where inherent variability and uncertainty are present. In this study, we utilize FCM, PCM, and PFCM on a dataset of 50 individuals' systolic and diastolic blood pressure values to classify them into low, normal, and high blood pressure groups. By comparing these three clustering techniques, this research aims to demonstrate the effectiveness of PFCM in providing robust, nuanced insights, especially for identifying borderline and high-risk individuals, thereby supporting preventive health interventions and monitoring strategies [1–12].

Fuzzy Mathematical tools

Definition 2.1

Let X be a universal set. A fuzzy set [13] A in $X$is defined as a set of ordered pairs

$$A = \{(x, \mu_A(x)) \mid x \in X\}$$

where$\mu_A(x): X \to [0,1]$is the membership function of the fuzzy set A. The value $\mu_A(x)$represents the degree to which element x belongs to the fuzzy set A.

Fuzzy C-Means Clustering

Fuzzy C-Means (FCM) clustering is an unsupervised soft clustering technique that partitions a dataset into $c$clusters by minimizing the objective function

$$J_m = \sum_{i=1}^{c} \sum_{j=1}^{n} u_{ij}^m \parallel x_j - v_i \parallel^2$$

where$u_{ij} \in [0,1]$represents the degree of membership of data point $x_j$in the i^{th}cluster, $m > 1$is the fuzzification parameter, $v_i$is the center of the i^{th}cluster, and the memberships satisfy

$$\sum_{i=1}^{c} u_{ij} = 1, \forall j.$$

This formulation allows each data point to belong to multiple clusters with different degrees of membership.

Possibilistic C-Means (PCM) Clustering

Possibilistic C-Means (PCM) clustering is a soft clustering method that enhances Fuzzy C-Means (FCM) by allowing each data point's membership in a cluster to be independent of other clusters. This approach minimizes the impact of

outliers and noise, as a point can have low membership across all clusters instead of being compelled to belong to one. PCM is particularly advantageous for datasets where certain points do not clearly fit into any cluster. PCM minimizes the following objective function:

$J_{PCM} = \sum_{i=1}^{c} \quad \sum_{j=1}^{n} \quad u_{ij}^{m} \parallel x_j - v_i \parallel^2 + \sum_{i=1}^{c} \quad \eta_i \sum_{j=1}^{n} \quad (1 - u_{ij})^m$

Membership Update Rule:

$$u_{ij} = \frac{1}{1 + \left(\frac{\|x_j - v_i\|^2}{\eta_i}\right)^{\frac{1}{m-1}}}$$

Cluster Centre Update:

$$= \frac{\sum_{j=1}^{n} \quad u_{ij}^{m} x_j}{\sum_{j=1}^{n} \quad u_{ij}^{m}}$$

Possibilistic Fuzzy C-Means (PFCM) Clustering

Possibilistic Fuzzy C-Means (PFCM) clustering is a soft clustering technique that merges the strengths of Fuzzy C-Means (FCM) and Possibilistic C-Means (PCM). This method integrates fuzzy membership to manage overlapping clusters and possibilistic membership to minimize the impact of outliers, enabling data points to be part of multiple clusters while remaining resilient to noise. PFCM is especially useful for medical and real-world datasets where uncertainty and outliers are present.

Objective Function:

The PFCM algorithm minimizes the following objective function:

$$J_{PFCM} = \sum_{i=1}^{c} \quad \sum_{j=1}^{n} \quad u_{ij}^{m} \parallel x_j - v_i \parallel^2 + \sum_{i=1}^{c} \quad \sum_{j=1}^{n} \quad t_{ij}^{m} \eta_i \parallel x_j - v_i \parallel^2$$

where:

- $u_{ij} \in [0,1]$is the fuzzy membership of point $x_j$in cluster$i$,
- $t_{ij} \in [0,1]$is the possibilistic membership of point $x_j$in cluster i,
- $v_i$is the cluster center,
- $m > 1$is the fuzziness parameter,
- $\eta_i > 0$is a scale parameter controlling the possibilistic membership,
- $\parallel x_j - v_i \parallel$is the Euclidean distance between the point and cluster center.

Membership Update Rules:

1. Fuzzy Membership u_{ij}:

$$u_{ij} = \frac{1}{\sum_{k=1}^{c} \quad \left(\frac{\|x_j - v_i\|}{\|x_j - v_k\|}\right)^{\frac{2}{m-1}}}$$

2. Possibilistic Membership t_{ij}:

$$t_{ij} = \frac{1}{1 + \left(\frac{\|x_j - v_i\|^2}{\eta_i}\right)^{\frac{1}{m-1}}}$$

3. Cluster Centre v_i:

$$v_i = \frac{\sum_{j=1}^{n} \quad (a\, u_{ij}^{m} + b\, t_{ij}^{m}) x_j}{\sum_{j=1}^{n} \quad (a\, u_{ij}^{m} + b\, t_{ij}^{m})}$$

where$a$and $b$are weighting parameters for fuzzy and possibilistic memberships, respectively.

Background of the Data

This table 3.1 outlines the blood pressure information for 50 individuals from various departments. It includes details such as department, name, gender, age, systolic and diastolic blood pressure, and the corresponding blood pressure category for each person. Individuals are categorized into Low, Normal, or High blood pressure groups based on their systolic and diastolic readings. The table indicates that a significant number of people, particularly those who are middle-aged and older, fall into the High blood pressure category, whereas Normal blood pressure is more prevalent among younger individuals. Only a small number of individuals are noted to have Low blood pressure.

Overall, the table offers a comprehensive view of blood pressure distribution across different departments, aiding in identifying those who may need regular health monitoring or preventive care. Department (Dept.), Systolic (Syt.), Diastolic (Dias.)

Fuzzy Mathematical Results

Fuzzy C-Means Clustering

The table 4.1 illustrates the outcomes of utilizing Fuzzy C-Means clustering on the blood pressure data of 50 individuals. Each person's Systolic and Diastolic readings are employed to ascertain their cluster affiliation. The FCM algorithm designates a cluster with the highest membership to each person while also offering membership values for all three clusters. In this table, Cluster 1 represents Low BP, Cluster 2 signifies Normal BP, and Cluster 3 indicates High BP. Individuals with lower blood pressure, such as R. Kavitha and S. Brundha, exhibit high membership in Cluster 1, whereas those with moderate BP, like R. Mercy and P. Sangeetha, are predominantly in Cluster 2. Individuals with elevated blood pressure, such as N. RaajaRajeswari and V. MohanaSundaram, display high membership in Cluster 3. The membership values indicate the extent of each individual's association with all clusters, capturing the fuzzy nature of blood pressure categories where a person's BP may not fit neatly into one category. This table offers a comprehensive, quantitative perspective on blood pressure patterns and the overlaps between Low, Normal, and High BP categories, facilitating the identification of individuals at risk of hypertension while also considering borderline cases.

Cluster Assigned(C.A), Membership Cluster 1(MS.C1), Membership Cluster 2(MS.C2), Membership Cluster 1(MS.C3)

The scatter plot 4.1 illustrates the application of Fuzzy C-Means clustering to blood pressure data, with systolic blood pressure plotted on the x-axis and diastolic blood pressure on the y-axis. Each dot signifies an individual, colored to indicate their cluster group: red for low blood pressure, green for normal, and blue for high blood pressure. Large black crosses denote the cluster centers, representing the average blood pressure for each category. The red cluster is situated in the lower ranges of both systolic and diastolic values, the green cluster is in the middle range, and the blue cluster encompasses the higher blood pressure values. This visualization demonstrates how individuals are categorized based on their blood pressure levels, with some overlap between clusters due to the fuzzy nature of the classification, indicating that some individuals may partially belong to multiple categories. Overall, the plot effectively shows the natural grouping of blood pressure measurements, aiding in identifying individuals with normal, low, or high blood pressure.

Possibilistic C-Means Clustering

The table 4.2 displays the results of clustering blood pressure data for 50 people using a technique akin to Possibilistic C-Means. Each person's systolic and diastolic blood pressure readings are shown, along with the cluster they are most closely linked to, determined by the highest membership value. The three clusters signify different blood pressure categories: Cluster 1 is associated with low blood pressure, Cluster 2 with normal blood pressure, and Cluster 3 with high blood pressure. The membership values for these clusters indicate the extent to which each person belongs to each category, illustrating the fuzzy boundaries between them. Individuals with lower blood pressure tend to have a strong association with Cluster 1, those with average readings are mainly in Cluster 2, and those with higher blood pressure are mostly in Cluster 3. The membership values reveal that some individuals can partially belong to multiple clusters, capturing the natural variation and overlap in blood pressure levels. This detailed clustering approach helps identify individuals with borderline or mixed blood pressure profiles, providing a more nuanced perspective beyond simple categorical labels.

Cluster 1(C1), Cluster 2(C2), Cluster 3(C3)

The graph 4.2 illustrates the outcomes of clustering blood pressure data using a technique akin to Possibilistic C-Means. Each dot signifies an individual, with systolic blood pressure plotted on the x-axis and diastolic blood pressure on the y-axis. The color of the dots corresponds to their cluster assignment: red indicates low blood pressure, green signifies normal blood pressure, and blue represents high blood pressure. Black X's mark the cluster

centers, which denote the average systolic and diastolic values for each category. The plot reveals that individuals with lower blood pressure are grouped in the lower-left area (red cluster), those with average blood pressure are situated in the central area (green cluster), and individuals with higher blood pressure are located in the upper-right area (blue cluster). Some overlap between clusters is apparent, highlighting the fuzzy or possibilistic nature of the clustering, where individuals might partially belong to multiple clusters. Overall, the graph offers a clear visual representation of how individuals are grouped based on their blood pressure levels, emphasizing patterns of normal, low, and high blood pressure, and facilitating the identification of borderline or at-risk cases.

Possibilistic Fuzzy C-Means (PFCM)

The table 4.3 displays the results of clustering blood pressure data for 50 people using the Possibilistic Fuzzy C-Means (PFCM) method. Each entry includes a person's name, their systolic and diastolic blood pressure readings, the cluster they are categorized into, and the fuzzy and possibilistic membership values for each cluster. The cluster assignment is determined by the highest fuzzy membership value, indicating whether a person is classified into low, normal, or high blood pressure categories. Fuzzy membership values (C1–C3) show the relative extent to which each person belongs to each cluster, while possibilistic values indicate the absolute degree of membership, reflecting how strongly an individual is associated with a cluster, independent of others. Individuals with lower blood pressure are mainly in Cluster 1 (low BP), those with average readings are mostly in Cluster 2 (normal BP), and those with higher readings are primarily in Cluster 3 (high BP). The combination of fuzzy and possibilistic values highlights cases where individuals may partially belong to multiple clusters, offering a detailed and adaptable perspective on blood pressure patterns. This approach captures both typical and atypical cases, aiding in health risk monitoring and identifying individuals who might require attention even if their readings are not extreme.

Fuzzy C1(FC1), Fuzzy C2(FC2), Fuzzy C3(FC3), Possibilistic C1(PC1), Possibilistic C2(PC2), Possibilistic C3(PC3).

The graph 4.3 illustrates the outcomes of applying Possibilistic Fuzzy C-Means (PFCM) clustering to the blood pressure data of 50 people. Each dot represents an individual, with the x-axis indicating systolic blood pressure and the y-axis indicating diastolic blood pressure. The color of the dots signifies their cluster assignment: red for low blood pressure, green for normal blood pressure, and blue for high blood pressure. The size of each dot signifies the possibilistic membership, with larger dots showing a higher confidence level that the person belongs to that cluster. Black X's denote the centers of each cluster, symbolizing the average blood pressure values for the low, normal, and high blood pressure categories. The graph visually displays how individuals are categorized based on their blood pressure measurements, with some overlap between clusters indicating borderline cases where individuals may partially belong to multiple clusters. Overall, the plot offers a clear and intuitive view of blood pressure distribution, helps identify normal and abnormal patterns, and highlights individuals who might be at risk, reflecting the fuzzy and possibilistic characteristics of the PFCM clustering approach.

The comparison graph 4.4 illustrates the clustering outcomes of blood pressure data using three techniques: Fuzzy C-Means (FCM), Possibilistic C-Means (PCM), and Possibilistic Fuzzy C-Means (PFCM), displayed in three adjacent panels. Each dot signifies an individual's blood pressure, with the x-axis representing systolic BP and the y-axis representing diastolic BP. Across all panels, dots are coloured based on their cluster assignment (red for low BP, green for normal BP, blue for high BP), and the size of the dots indicates the membership strength, which is either fuzzy or possibilistic depending on the method used. The black X's mark the cluster centres. In the FCM panel, clusters demonstrate the fuzzy nature of membership, with overlaps indicating individuals who partially belong to multiple clusters. The PCM panel highlights absolute membership confidence; clusters are more compact, and dots with lower confidence are smaller, minimizing the impact of outliers. The PFCM panel integrates both fuzzy and possibilistic data, balancing relative membership with absolute confidence. This panel distinctly shows both overlaps and membership certainty, making it the most comprehensive representation of cluster structure. Overall, the side-by-side comparison reveals how each method addresses uncertainty and borderline cases, showcasing the subtle benefits of combining fuzzy and possibilistic clustering for analysing blood pressure patterns.

RESULTS AND CONCLUSION

The analysis of blood pressure data from 50 individuals employed Fuzzy C-Means (FCM), Possibilistic C-Means (PCM), and Possibilistic Fuzzy C-Means (PFCM) clustering techniques to categorize individuals into low, normal, and high blood pressure groups. FCM allocated individuals to clusters based on the highest fuzzy membership, which highlighted overlaps where borderline cases partially belonged to multiple clusters, but it sometimes exaggerated the relative membership for extreme values. PCM emphasized absolute membership, resulting in more compact clusters and minimizing the impact of outliers, with individuals of uncertain blood pressure appearing less prominent, although it underestimated relative relationships in overlapping areas. PFCM merged the strengths of both methods, balancing fuzzy overlaps and absolute membership confidence, effectively capturing borderline cases and providing a robust clustering structure. Visual representations indicated that individuals with low blood pressure were primarily in Cluster 1, those with normal BP in Cluster 2, and those with high BP in Cluster 3, with several borderline cases clearly identified by PFCM. The analysis also uncovered patterns across age and department groups, showing that high blood pressure was more prevalent among older individuals, while younger individuals tended to cluster in low or normal BP groups. Overall, PFCM provided the most comprehensive insight, identifying high-risk individuals and nuanced borderline cases, demonstrating the effectiveness of fuzzy and possibilistic clustering techniques in analysing health data.

CONCLUSION

This work highlights the efficacy of clustering techniques such as Fuzzy C-Means (FCM), Possibilistic C-Means (PCM), and Possibilistic Fuzzy C-Means (PFCM) in examining blood pressure trends with support of PYTHON tool. FCM was adept at capturing fuzzy overlaps, making it effective in identifying borderline cases. PCM focused on absolute membership, minimizing the impact of outliers and forming compact clusters. PFCM merged the strengths of both methods, balancing relative and absolute membership to offer a more robust and nuanced clustering solution. The study found that high blood pressure was more common among older adults, whereas younger individuals generally fell into low or normal BP clusters. PFCM was particularly effective in identifying individuals with blood pressure readings near critical thresholds, making it a valuable tool for health monitoring and early detection of those at risk. Overall, the study confirms that fuzzy and possibilistic clustering methods offer insightful, flexible, and reliable approaches for analysing complex health data, enabling the identification of typical patterns and the detection of borderline or high-risk cases. These methods can aid healthcare decision-making, preventive measures, and targeted monitoring of individuals with diverse blood pressure profiles.

ABSTRACT

The necessity to produce innovative and quality products that meet the changing consumer preferences in the market is increasingly becoming a key motivation for New Food Product Development (NFPD). Nevertheless, the methodology of the traditional approaches is rather problematic, which encompasses prolonged periods of development, a lack of assurance in terms of acceptance among the consumers, and subjective evaluation of sensory. This review examines how artificial intelligence (AI) can be used transformatively in solving these limitations throughout the food product development pipeline, with specific emphasis on sensory evaluation. The application of AI technologies, e.g., machine learning (ML), deep learning (DL), electronic sensing systems (e-nose, e-tongue), and computer vision, allows predicting the sensory qualities and customer preferences using a combination of chemical, visual, and physicochemical data. Multimodal data fusion also increases the accuracy of predictability due to the development of multifaceted interaction between this data and the perception of flavours. Case studies show that AI models are capable of effectively forecasting such sensory traits as sweetness, aroma, and overall liking, eliminating the need to rely on time-consuming panels of human subjects. In spite of these developments, there are still problems with the standardisation of data, model interpretability, and the combinations of heterogeneous data. The review indicates the future opportunities of explainable AI, digital twins, and personalised nutrition and outlines how AI may streamline innovation and make the

design of food more efficient and consumer-centric. In general, AI is a paradigm of the revolution in data-based sensory analysis and smart NFPD technologies.

Keywords: Artificial intelligence; Sensory evaluation; Machine learning; Food product development; Consumer preference prediction

INTRODUCTION

New Food Product Development (NFPD) is a multidisciplinary, intricate and multifaceted process, which encompasses the design, formulation, optimisation, and commercialisation of new food products that satisfy the emerging consumer preferences, regulations and also sustainability objectives. Recently, NFPD has been considered to be a consumer- and sustainability-based innovation system that involves food science, sensory assessment, engineering, and marketing in enhancing the success rate of products and reducing the risk of their development (Azanedo et al., 2020; Guiné et al., 2020). Normally, NFPD will embrace systematic steps like idea generation, formulation, prototyping, sensorial evaluation and commercialisation, but in reality, it is frequently an iterative and fragmented process that consumes a lot of resources. NFPD has a number of challenges that remain to be addressed. A significant problem is that new food products have one of the highest failure rates, which is often stated to be between 75% and 90%, many of them because of a poorly organised development process and insufficient knowledge of the market needs (Azanedo et al., 2020; Kumar et al., 2021). Scattered food companies (especially small and medium-sized ones) continue to employ non-standardised, ad hoc strategies as opposed to food-specific, systematic development strategies. This is also complicated by specific features of food systems, such as low shelf-life, variability of raw materials, and strict regulatory and nutritional standards, which add complexity to their development (Azanedo et al., 2020; Zeefat & Marczewska, 2025).

The other serious obstacle is the long time-to-market,which restricts a firm from being able to respond to evolving consumer trends in a quick manner. The product development process can be characterised by a repetitive series of formulation readjustment and sensory testing, which has additional costs and time delays. Tightly connected to this is the inability to forecast preferences of consumers that are dynamic and affected by various factors, including health awareness, culture, food neophobia, and readiness to pay (Guiné et al., 2020; Tian & Kamran, 2023), in particular. Another typical misapplication of NFPD traditional belief is that high product quality is the automatic guarantee of its success in the marketplace, yet numerous failures have to happen when it is not aligned with the expectations of consumers (Kumar et al., 2021). Besides, sensory variability is also a significant limitation. The sensory attributes that could be affected by lack of consistency in raw materials, processing conditions, and storage include taste, aroma and texture, which in the end result in the consumer acceptance. NFPD is thus focused on sensory evaluation, and it is recommended to dynamically combine descriptive analysis, hedonic testing and consumer research into the process of development (Drake et al., 2023; Ruiz-Capillas et al., 2021). Nevertheless, traditional sensory techniques are very focused on trained panels and consumer testing, which is time and money-consuming, and is also not scalable.

The field is currently undergoing a methodological revolution to a more structured, data-driven and technology-enabled methodology to overcome these drawbacks. New models promote food-specific stage-gate models, system lifecycle management, and value-chain-based development strategies, which combine consumer insights, sustainability, and technological innovation (Alongi & Anese, 2021; Tian & Kamran, 2023). At the same time, the objectivity and context of sensory analysis are increasing due to the emergence of such new tools as digital sensory technologies, e.g., eye tracking, electronic nose and tongue, and virtual reality (Cosme et al., 2025). Artificial intelligence (AI) and machine learning (ML) are disruptive technologies in food science and NFPD in this changing context. The methods of AI allow high-dimensional and complex datasets, including chemical composition, spectral fingerprints, and physiological reactions, to be analysed to model the relationship between product properties and sensory perception. For example, machine learning models including Gradient Boosting and Extreme Gradient

Boosting have successfully predicted sensory attributes and consumer preferences in diverse food systems such as wine, beer, cheese, coffee, and fermented beverages (Armstrong et al., 2023; Curto et al., 2020; Schreurs et al., 2024; Zou et al., 2024; Natsume & Okamoto, 2025). Such predictive capabilities will greatly alleviate the use of traditional sensory panels, but include a faster formulation optimisation.

Besides, the development of multimodal data integration has improved the prediction precision of AI systems. Facial emotion recognition approaches with physiological measurements and sensory scores give a more precise picture of consumer responses than the traditional approaches (Álvarez-Pato et al., 2020). Other areas where AI is being used are ingredient substitution, formulation optimisation, and sustainable product design, thus helping to improve a transition toward more efficient and predictive NFPD systems (Datta et al., 2025; Oz & Oz, 2025). These achievements still do not contribute to the complete adoption of AI in NFPD because of a number of obstacles. These are the unavailability of unified datasets, challenges in unifying heterogeneous data sources, and issues of model interpretability and transparency (Gunning & Tagkopoulos, 2025; Zhang et al., 2019). These issues must be dealt with as they will provide confidence, fidelity, and mass implementation of AI-inspired solutions in the food industry. Thus, this review can be seen as an attempt to investigate how AI tools can be used at various phases of NFPD, specifically how they can be used to predict sensory parameters and customer acceptance. This review analyses the possible and the drawbacks of the potential of AI to revolutionise sensory analysis and speed up food product development by synthesising the existing literature.

Overview of AI Technologies in Food Systems

Artificial intelligence (AI) has become a game changer in the areas of contemporary food systems, and it has allowed the shift towards the traditional and reactive processes to the area of data-driven, predictive, and interconnected farm-to-fork ecosystems. Food safety, quality controls, supply chain optimization, and product development have been enhanced greatly due to the integration of AI technologies (including machine learning (ML), deep learning (DL), computer vision, natural language processing (NLP), digital twins, and big data -Internet of Things (IoT) systems) (Dhal & Kar, 2025; Aghababaei et al., 2025; Yin et al.,2025). When all these technologies are combined, they allow the capture, analysis, and use of the complex data sets all along the food value chain, production, processing, distribution and consumption, helping to make smarter decisions. Modern food technology encompasses various disciplines of food science, food engineering, nutrition, microbiology and biotechnology, which are used to create safe, nutrritious and consumer-accepted foods. Food processing technologies are intended to retain the food's shelf life and the food's microbial safety, as well as its nutritional quality, functional properties and sensory characteristics. In recent years, functional foods, fortified food, low fat and sugar reduced food, gluten free and plant based alternatives, and food and products for personalised nutrition have been developed to meet the needs of various consumers. At the same time, consumers demand healthier foods, less processing and more sustainable foods, driving forward the innovative technologies that can keep product quality while making manufacturing more efficient. Nutritional optimization has also become a fundamental goal in the product development process and is referred to as the balance between macronutrients, the micronutrients and the bioactive compounds and the acceptability sensory aspects. As a result, food industries are starting to combine digital processes with traditional food engineering approaches for making decisions during product development, processing, quality control and customer assessment.

Machine Learning (ML)

Machine learning will be the basis of AI practice in food systems since models learn trends in historical and real-time information to predict and optimise processes. Regression models, decision trees, support vector machines, and ensemble algorithms are used to a large extent in food safety, quality determination and supply chain management. Specifically, ML has managed to find its way into the Hazard Analysis and Critical Control Point (HACCP) systems, where it can facilitate the evaluation of the risk and the detection of contamination based on the data provided by the spectroscopic sensor devices, hyperspectral imaging and microbiological tests (Revelou et al., 2025; Deng et al., 2021). ML models have shown applications in food safety to anticipate food borne outbreaks and charting risks of food contamination by uniting data that is comprised of microbial analysis, merchandising flows and examination history

(Wang et al., 2021). In the same way, quality grading and classification are also performed in the sphere of ML to filter the visual, spectral, and sensor-based data with the aim to measure such attributes as freshness, ripeness, and defects of raw and processed foods (Liakos et al., 2025; Saha & Manickavasagan, 2021). The accuracy and flexibility of the ML models are higher compared to traditional rule-based systems, especially when large and heterogeneous datasets are being worked with. Other than the safety issues and quality, ML is also very important in the optimisation of supply chains, such as demand forecasting, shelf-life prediction, and logistics planning. ML models would achieve the goals of decreasing food waste and increasing operational efficiency by comparing historical consumption trends and the state of the environment (Dhal & Kar, 2025; Aghababaei et al., 2025). Such functions are especially necessary in perishable food systems, where fast decision-making is the key to preserving quality and preventing losses.

Deep Learning (DL)

Multi-layer neural networks, commonly referred to as deep learning in the subset of machine learning, have been very prominent because of their capability to process high-dimensional and complex data, including images, videos and sensor streams. Meanwhile, in a task involving feature extraction and pattern recognition, DL models and, in particular, convolutional neural networks (CNNs) have shown a high performance level compared to classic ML models (Zhou et al., 2019; Saha & Manickavasagan, 2021). Knowing precise quantities and nutritional value, DL is widely applied in food systems, with automated food recognition and dietary evaluation, whereby image models are able to detect food materials, size a portion, and estimate nutritional data. These applications assist with consumer-targeted technologies like dietary tracking and individualised nutrition via mobile applications (Aghababaei et al., 2025). Also, DL is actively used in the areas of quality and safety checks where it is possible to detect the presence of defects, spoilage, and contamination in products (fruits, vegetables, meat and seafood). Another example that has been noted is the use of DL in industrial quality control, where real-time inspection systems can be very precise. Indicatively, deep learning-based solutions have been claimed to identify packaging flaws in thermoformed food packaging with a precision rate of over 99.9%, and this aspect indicates that they are highly dependable in high-throughput manufacturing systems (Banús et al., 2021). The fact that the DL models are capable of automatically learning the relevant features out of the raw data will decrease the need to use the manual feature engineering system and, therefore, enable them to be highly scalable and adaptive to various food applications.

Computer Vision

Computer vision solutions, typically with ML and DL codes, can deliver the visual intelligence needed with automated inspection and monitoring in food systems. Such systems are based on imaging technologies, including RGB cameras, hyperspectral imaging, and multispectral sensors, to obtain visual data, and then analysed to evaluate the quality of the products and identify anomalies. Computer vision can be used for food sorting, grading, and defect detection, and as a quality assessment criterion, visual characteristics such as colour, shape, size, and surface texture are utilised (Zhou et al., 2021; Xiao et al., 2022). As an example, computer vision systems have the ability to spot bruising in fruits, marbling in meat, or mould in processed foods and allow a uniform and objective judgment of quality. This will substitute the manual inspection, which is normally subjective, difficult and can be variable. Moreover, computer vision is very important in foreign object detection as well as in packaging inspection to guarantee the safety of products and regulatory confirmation. Contaminants like metal or plastic fragments, label accuracy and seal integrity are some contaminants that can be detected by automated systems in packaging lines (Xiao et al., 2022). These are features that not only improve food safety but also consumer security as well as increasing the efficiency of operations.

Natural Language Processing (NLP)

Natural language processing allows the analysis of non-structured textual data that is rich in food systems, such as regulatory documents, inspection reports, scientific literature, and consumer feedback. The extraction of valuable insights based on the following data sources is possible with the use of NLP techniques, such as text mining, sentiment analysis, and topic modelling. NLP is applied in the context of food safety to keep track of the regulatory compliance and identify developing risks using the data on inspection reports, recall notices, and policy documents

(Dakhia et al., 2025). Indicatively, multiple deep learning systems that integrate both NLP and time-series data have been trained to forecast the risk of a food recall on the basis of the past recall instances and textual explanations (Makridis et al., 2022). This allows for risk intervention and avoidance. There is also the use of NLP in consumer feedback analysis through analysing the online reviews and social media data to determine the consumer preferences, product complaints, and emerging quality concerns. Such observations are usable in developing products, marketing and quality improvement efforts. In addition, NLP helps in customised nutrition, in which user-generated data and diets are evaluated to report specific recommendations (Aghababaei et al., 2025).

Digital Twins in Food Design and Processing

Digital twins are a new paradigm of AI-powered food systems, which entails the development of virtual copies of physical products, processes, or systems. They combine real-time sensor and IoT data with simulation and artificial intelligence algorithms in these models to allow analysis and optimisation based on predictions. Digital twins can be applied to modelling process parameters and results in food processing (i.e., microbial inactivation, texture formation, shelf-life variations, etc.) under varying conditions. This enables what-if analyses and research, and manufacturers can do such tests without experimentation. As an illustration, the optimisation of advanced technologies of processing, including high-pressure, pulsed electric field, and cold plasma, can be optimised using digital twins (Dhal & Kar, 2025; Yin et al., 2025). Furthermore, digital twins are helpful in the control of the processes in real-time as they constantly update models by receiving live sensor data, which allows them to optimise production systems adaptively. This is in line with the concepts of Industry 4.0 and Industry 5.0, where cyber-physical systems use efficiency to promote efficiency, sustainability, and resilience in food manufacturing.

Big Data and IoT Integration

The combination of big data and IoT is the basis of the current AI-driven food systems. The IoT gadgets, such as the sensors, intelligent packaging, and linked equipment, allow monitoring of the environmental conditions, including temperature, humidity, and concentration of gases, along the supply chain. Such streams of data are delivered to central stations, where they can be aggregated together and processed with AI algorithms. The integration of the various forms of data, such as sensor data, images, genomic data, transaction data, and textual data, is facilitated by big data platforms that provide the ability to conduct wholesale analysis of this data (Dakhia et al., 2025). The applications that are supported by this integration include predicting spoilage in real-time, identifying contamination, and modelling the shelf- life to enable the use of proactive decisions. Artificial intelligence analytics can be used in supply chain management to predict demand and logistics and allocate resources more efficiently and with lower waste. More sophisticated methods are actively applied, which include deep reinforcement learning to optimise routing and inventory in dynamic settings (Dakhia et al., 2025). Also, traceability systems, usually supported by blockchain technology, facilitate transparency and responsibility in the food supply chain due to the use of IoT technology. Food computing is a term used to describe this type of integration of AI, IoT, and big data and strives to develop intelligent systems that enhance safety, efficiency, and personalisation throughout production to consumption (Dakhia et al., 2025). Individually, as an example, personalised nutrition systems take the data on nutrition, the health parameters, and the database on food constituents and provide a customised prescription based on the needs of the individual.

Cross-Cutting Impacts and Challenges

In all these technologies, AI helps in making major contributions to food safety, quality assurance, and sustainability. Quick detection of pathogenicity, future risk forecasting, and tracing end-to-end help in improving safety, automated checking and optimisation of processes to improve quality and waste reduction (Dhal & Kar, 2025; Yin et al., 2025). Nonetheless, there are a number of obstacles, such as the unavailability of data, standardisation deficiency, integration with the old systems, and explainable and transparent models. Data security and privacy issues are also part of the ethical considerations that should be established to promote fair use of AI technologies. On the whole, ML, DL, computer vision, NLP, digital twins, and interconnected big data-IoT integration are transforming food systems into intelligent, adaptive, and interconnected systems, due to which a food system can be innovative and resilient across the whole value chain.

AI Across the Food Product Development Pipeline

Artificial intelligence (AI) is finding its way into the whole New Food Product Development (NFPD) pipeline, and traditional linear and trial-and-error pipelines have turned into data-driven systems, iterative and predictive systems. Innovative AI applications (natural language processing (NLP), optimisation algorithms, simulation models, and computer vision) are already making the process of food innovation more efficient, consumer-percentage and safer in the first place, from early-stage ideation up to final quality assurance. These technologies are synergistic, meaning they are used in conjunction, enabling a constant feedback loop between the various stages of the process and making the cycles of product development more agile (Dhal & Kar, 2025). Food product development is a systematic and specific process of designing, formulating, processing, evaluating and commercializing food products, which are suitable and acceptable by the consumers and conserving the safety, nutritional and regulatory parameters. The traditional approach to creating new products has been to test multiple formulations and processing conditions in the laboratory, apply a series of expert judgments, conduct sensory panel tests and/or market surveys to maximize product optimization. The majority of conventional food products (e.g., dairy, bakery, beverages, cereal, confectionery and meat products) are formulated using an incremental approach. Novel food products on the other side mean functional food, fortified food, plant based food, therapeutic food, sports nutrition food and personalized nutrition food that require an adequate selection and optimization of ingredients to meet new health and lifestyle requirements. As these products get more complex, there has been a tendency to use artificial intelligence that allows for fast data analysis, product quality prediction, formulation optimization, and decreased product development time as opposed to other traditional trial and error methods.

Ideation and Market Analysis

NFPD ideation stage has traditionally been based on three elements, which are market surveys, expert instinct and historical sales. Nonetheless, AI, in general, and NLP in particular, has elevated the level of extracting practical insights from huge amounts of unstructured consumer data. NLP trend mining has become a major tool to monitor the opportunities of food trends, consumer trends and innovation opportunities. Based on the results of the analysis of the social media platforms, online reviews, blogs, and discussion forums, the NLP methods period topic modelling, latent semantic analysis, and clustering will be applied to reveal the recurring themes and emerging product characteristics (Dash et al., 2023; Kauffmann et al., 2019). As an example, the increasing interest in plant-based food, clean-label products, or functional ingredients may be uncovered using such approaches, and the firm could modify the concepts of products accordingly. Notably, NLP enables real-time trends monitoring, which is a dynamic substitute to existing, time-lagged market analysis practices. NLP can be used to analyse the product features at a fine scale as well as in determining trends in addition to mapping certain attributes to consumer perceptions; this may be the flavour, texture or packaging of the product. It enables the developers to realise what consumers are speaking of, as well as how they assess certain product qualities, thus presenting more focused concept development (Kauffmann et al., 2019).

Consumer sentiment analysis, which adds to trend mining, will give more insights regarding the emotional reactions to the food products. The techniques of sentiment analysis can be run on a document, sentence, and aspect level in order to categorise the opinions as positive, negative, or neutral, and to determine a particular cause of satisfaction or dissatisfaction (Wankhade et al., 2022). Further technologies also include the use of emotion, which requires more subtle responses (e.g., trust, anticipation, or disgust), which are essential in food acceptance (Verza et al., 2023). The insights also help companies to develop refined product concepts at an early stage of the product development process, which minimises the chances of failure because of failure to align with the consumer expectations. Additionally, the recent methods combine semantic networks and knowledge graphs to associate ingredients, product characteristics, and consumer feelings. It makes it possible to identify the so-called high-reputation formulations, wherein some aggregate of ingredients is repeatedly linked to the positive consumer attitudes, e.g. the naturalness or healthiness (Cui et al., 2025). Altogether, AI-based ideation makes the front aspect of NFPD more evidence-based and consumer-oriented.

Ingredient Selection and Formulation

The formulation stage is the process of picking ingredients and the amount of these ingredients in order to obtain the desired sensory, nutritional and functional qualities. This stage is, by nature, multifaceted because of the nonlinear interaction between the ingredients, as well as the necessity to strike a balance among the objectives. The new AI has offered effective tools to solve these problems. A major part of AI-driven formulation is given up by optimisation algorithms. Genetic algorithms, particle swarm optimisation, artificial bee colony, and grey wolf optimisation are known as bio-inspired algorithms and may be especially successful with a high-dimensional and nonlinear solution space (Sarkar et al., 2022). The algorithms are used to find optimal or near-optimal formulations by searching through formulations, routinely imitating natural processes, and enabling the simultaneous maximisation of a variety of criteria, including taste, texture, cost, and nutritional value.

Also, Bayesian optimisation has become popular due to its ability to perform the optimisation of experiments that are costly or time-intensive. Bayesian methods can be used to find promising formulation candidates using fewer experimental runs because they can construct probabilistic models of the objective function (Wang et al., 2022). These strategies are being actively developed into the virtual formulation platforms that allow screening and refining the ingredient combinations fast (Liakos et al., 2025). An essential usage of AI in formulation is the nutritional balancing, where models are utilised to produce products, creating a diet-appropriate product without damaging sensory characteristics. As an example, computational models can be used to optimise the amino acid content of multi-ingredient products to fulfil the standards of the World Health Organisation (WHO), especially in plant-based or functional food (Kambarova et al., 2025). Machine learning models can also be used to assess the context of ingredient substitution and make more sustainable or healthy products that do not reduce consumer acceptance (Liakos et al., 2025).

Furthermore, AI allows to consider the input of consumers in the process of making formulations. The combination of the ingredient information with sentiment analysis results allows the developers to define the combinations of ingredients that were deemed as the most optimal in terms of their nutritional value and that are the most appreciated by the customers (Cui et al., 2025). This is an economic reaction of technical optimisation to consumer-based formulation design. AI-based formulation strategies can be applied differently for various products. AI models enhance flour formulation, water absorption, fermentation settings, texture, crust colour and shelf life, which are specific challenges in bakery products. Machine learning is used in dairy foods like yogurts and cheeses to forecast fermentation takes place, flavor development and probiotic stability (Murugesan et al., 2026). AI is being applied to fine-tune sweetness, acidity, aroma compounds, carbonation and consumer likes use of fruit juices, tea, coffee, dairy beverages and functional drinks in beverage industry. Likewise, AI can be used in the development of therapeutic foods for diabetic, renal and cardiovascular patients to optimize the nutrient profile while maintaining sensory quality. For sports nutrition products, such as protein powders, protein bars, recovery drinks, and electrolyte drinks, AI can help optimize protein quality, amino acid composition, flavour masking, and even final product consumer acceptance.

Processing and Prototyping

Quality, safety, nutrition and senses are important factors in determining the quality of food products during food processing. While the conventional processing methods include thermal processing, pasteurization, sterilization, drying, fermentation, freezing, extrusion cooking and baking, the emerging techniques include high-pressure processing, pulsed electric field processing, ultrasound, cold plasma, microwave heating and ohmic heating are adopted in order to overcome various limitations of conventional methods to maintain the quality of food products while preserving the nutritional qualities. The best processing conditions will vary, depending on the food product, the intended shelf life, acceptability of the consumer and regulatory requirements. AI builds on those processing techniques, using predictive modelling and real-time monitoring to anticipate the best processing conditions, reduce processing losses, ensure a consistent product and provide intelligent process control.The processing and prototyping stage is associated with the transformation of formulations into tangible products by means of controlled conditions of processing.

AI is essential in streamlining these procedures, and it benefits in lessening the use of expensive experimental experiments. The effects of processing conditions on food structure and functionality are more often understood through process simulation models. Such simulations can include interactions between proteins, lipids, and carbohydrates at the molecular level by using molecular dynamics (MD) simulations, depending on a variety of different processing conditions (such as high pressure or thermal treatment) (Chen et al., 2018; Smith et al., 2022). Such simulations can give information as to how it will form a texture, whether it will be stable, and how safe it will be, making it possible to have a more informed design of the process, and then test it on a pilot scale before that information is applied in production. Bio-inspired optimisation algorithms are also used alongside, but not limited to, simulation in order to find the most effective processing parameters, i.e. temperature, time and input energy. They can be used in multi-constrained and multi-objective scenarios, such as the quality and efficiency of products and their prices, which makes them very applicable in complex food processing systems (Sarkar et al., 2022). The machine learning models also facilitate the optimisation of the workshop processes through the predictability of factors like the drying kinetics, gases emitted, and the impact of non-thermal processes during the storage (Dhal & Kar, 2025).

The other major direct usage is predictive shelf-life modeling which is based on AI and is used to predict the remaining shelf life of food items using several variables. Conventional shelf-life frameworks typically use single measures, e.g., microbial growth or chemical degradation, but AI frameworks are capable of combining various sources of information, e.g. environmental conditions, packaging properties, and product composition (Cui et al., 2023). ML models are neural networks that have been shown to be better at predicting the shelf life, thus aiding in the ADs, packages and distribution through better decisions (Rashvand et al., 2025). In addition, AI combined with IoT and sensor technologies can allow real-time monitoring of the shelf-life, which will make it possible to make dynamic changes in the conditions of storage and distribution. This minimises food wastage and improves the quality of products in the supply chain.

Quality Control and Safety

Safety and quality control are the last important stages in the NFPD pipeline in order to deliver products that are of the required standards and meet consumers' expectations. The speed, accuracy, and reliability of the quality assessment have been greatly increased with the help of AI technologies, specifically, ML, DL, and computer vision.AI has not only enhanced the quality inspection of food products but also played a substantial role in food testing across the entire food product development process. AI-driven testing encompasses quick identification of micro-organisms, detecting adulteration, analysis of contamination, nutritional content predictions, shelf-life predictions and packaging integrity monitoring. Computer vision systems are able to detect physical defects, hyperspectral imaging technologies identify chemical variations and electronic nose and electronic tongue technologies evaluate aroma and taste characteristics, without destroying the sample. Algorithms for machine learning combine these datasets and deliver quick and objective analyses of the products that are highly reproducible, eliminating or significantly decreasing the need to rely on traditional analysis in the lab and speeding up the commercialization of the products.

Contamination and adulteration detection AI-based is based on data from spectroscopy, imaging, and sensor detection to detect chemical, biological, and physical hazards. The level of detection of pesticides, mycotoxins, heavy metals and microbial pathogens by machine learning models has high detection rates ranging between 81-100% in most cases, depending on the application (Othman et al., 2023; Kuppusamy et al., 2024). The systems provide a quick, non-destructive method of testing that minimises the use of traditional laboratory techniques and also provide real-time analysis of food safety (Dhal & Kar, 2025). Simultaneously, using computer vision to identify flaws in data in the form of an image is a fundamental aspect of automated quality control. Using AI systems to detect spoilage and foul objects by analysing visual data like colour, shape, texture, and surface dents, AI systems enable companies to classify products. Image segmentation with the help of classifiers, namely, k-nearest neighbours (KNN), support vector machines (SVM), and decision trees, is among the techniques allowing differentiating between high-quality and defective products (Hemamalini et al., 2022).

The state-of-the-art systems include sensor fusion and hyperspectral imaging, which give a comprehensive picture of the external and interior product traits. These technologies can be applied to the inspection of non-destructive, high-throughput, and are, therefore, appropriate when it comes to industry-level implementation (Liakos et al., 2025). Notably, AI-based quality control systems are gradually turning into a complement to predictive models of shelf-life and IoT-based monitoring, which has formed a global quality freedom strategy of active safety control. This will enable the prevention of possible risks early enough, will decrease food waste, and will adhere to the regulatory requirements within the entire supply chain (Rashvand et al., 2025; Dhal & Kar, 2025).

In all parts of the food product development pipeline, AI technologies are making it possible to transform the innovation pathway to predictive, efficient and consumer-centred innovation. NLP and sentiment analysis provide real-time consumer information on ideation, and optimisation algorithms can optimise formulation design, simulation models, and ML can help increase processing efficiency, and AI-based quality control can guarantee product safety and consistency. All these technologies will decrease the time of development, reduce costs, and enhance the consistency with the tastes of consumers and statutory demands. Nevertheless, some issues are still present, such as data integration, model interpretability, and standard datasets. These concerns will need a solution so as to fully harness AI capabilities in turning NFPD into an entirely smart and adaptable system.

AI in Sensory Evaluation

Sensory evaluation has been revolutionised in food science through artificial intelligence (AI) to move it out of the subjective and human-based considerations to be a more objective and data-based prediction system. Sensory perception- research about the sense of taste, smell, touch, and sight is traditionally a complex, multidimensional element that is hard to measure using conventional techniques. AI and machine learning (ML) provide potent solutions to simulate such complexities with chemical composition, sensor results, and response of consumers grouped into predictive systems. This paper analyses the proposed shift in the conventional sensory approach towards an AI-based approach, namely electronic sensing technologies, multimodal modelling, and consumer preference prediction.

Traditional Sensory Methods vs AI

The use of traditional sensory means is mainly dependent on the use of human panels that are trained in order to evaluate the attributes of food, e.g., flavour, texture and aroma and to determine the overall acceptability of the food. Such techniques as descriptive analysis, hedonic testing, and ranking have been regarded as the gold standard in food science for a long time. They do, however, have a few constraints related to them. Subjectivity is one of the most important challenges. The perception of man is diverse because of physiological, psychological and environmental factors which result in inconsistencies in sensory outcomes. The perception of taste and aroma in individuals can be affected by genetic variations, mood, fatigue and cultural background, making inter-person variation in the reproducibility levels across panels. Moreover, panel-based assessments tend to be laborious and expensive, and take a lot of time to train and test and to control conditions to achieve a higher level of reliability (Yang et al., 2023). Low scalability is also another weakness. Human panels are impractical in conducting large-scale screening of a product or for real-time monitoring of quality. Moreover, the gathering of sensory data needs to be labelled, and this also relies on human factors and thus will affect the data with noise and biases (Lu et al., 2020). These limitations are fixed by the presence of an AI-based sensory system, which can make objective, reproducible, and high-throughput analysis. The machine learning models during the learning phase can be trained to predict the relationships between the measurable inputs (e.g., chemical composition, spectral data) and the sensory outputs, and thus decrease the use of human panels and increase the prediction accuracy (Fuentes, 2022). It is important to mention, however, that AI does not totally supplant human perception, but instead works in tandem with it, especially when it comes to model training and the model validation phase.

AI-Based Sensory Prediction

This is because AI sensory prediction systems seek to be similar to human sensory perception with respect to their technological application with electronic sensing systems and computational algorithms. The systems would usually

combine sensor arrays and machine learning algorithms to forecast the sensory qualities, e.g., flavour, aroma and texture.

Electronic Nose (E-nose)

An electronic nose (E-nose) is developed to replicate the human olfactory system, that is, it recognises volatile compounds used to create aroma. It is made up of gas sensor arrays that produce signal patterns that can be recognised as particular odour patterns. The MLs that are used to classify and predict aroma characteristics are support vector machine (SVM), artificial neural network (ANN), and random forests. E-nose technologies find their specific uses in flavour profiling and quality control because they are a high-speed and non-destructive approach to analysing volatile products. Together with the chromatographic methods, e.g., GC-MS, they improve the detection and description of aroma-associated aspects (Ge et al., 2025). E-nose systems are more consistent and even work continuously, as compared to human olfactory assessment, which is not very consistent in industrial environments.

Electronic Tongue (E-tongue)

The electronic tongue (E-tongue) is a device that is intended to replicate human taste by responding to sensor arrays that detect dissolved tastes that constitute taste qualities such as sweetness, bitterness, sourness and umami. They are sensors that produce electrical signals that are interpreted with machine learning models to transform them into taste profile classifications. E-tongue techniques have broad applications in beverage analysis, monitoring of fermentation, optimisation of products and give objective and repeatable measurements of taste. In the same way as E-nose systems, they can analyse a complicated mixture and present patterns that can hardly be identified by human panels (Yang et al., 2023).

Computer Vision for Texture and Colour

The Computer vision system is very important in assessing visual sensory properties such as colour, texture and appearance. These features have a great impact on food product perception and acceptance by consumers. The computer vision systems are capable of obtaining features like colour distribution, surface texture, and structural patterns using digital imaging and deep learning models. As an illustration, machine learning models trained on image-derived features have been trained to see the spinach freshness and have been as good as human sensory panels at classification (Koyama et al., 2021). The systems offer non-destructive, quick and objective measurements, and this qualifies them to be used in the real-time quality assessment of the food processing premises.

Multimodal Sensory Modelling

Sensory perception is multimodal by nature, as it implies the combination of taste, smell, texture, and visual perception. The application of AI will allow building multimodal models that will jointly predict the sensory information in order to enhance it and improve the accuracy. Multimodal sensory modelling merges such data as chemical data (e.g. metabolomics, volatile compounds), sensor data (E-nose, E-tongue) and visual data (computer vision) into single predictive models. Such a method is influenced by the biological fact of how a human mind perceives things, that several sensory data are being processed at once in order to create a whole experience. As an example, metabolomics data have been correlated with sensory traits and consumer liking rating of pepino fruit based on machine learning models to determine the important metabolites affecting the fruit's taste, acidity level, and intensity of the flavour (Sun et al., 2022). Equally, hybridised systems based on the use of E-nose, E-tongue and chromatographic have been created to expand flavour prediction and the identification of compounds (Ge et al., 2025).

Multisensor data fusion additionally enhances the predictive performance through the free association of complementary information from the various modalities. As an example, it has been demonstrated that incorporating machine learning models with electronic data on sensory data has at least an excellent predictive accuracy of sensory characteristics and consumer hedonics (Yang et al., 2023). Although having its benefits, multimodal modelling is complicated by data integration, complexity of the model and computation. Being able to ensure compatibility of the various types of data and also be able to interpret a model is important to consider in future research.

Consumer Preference Prediction Models

The use of AI in sensory evaluation predicting consumer preferences is one of the key objectives, as it directly affects the success of a product on the market. The machine learning models can predict like score, acceptance and hedonic in response to sensory and physicochemical data. Different machine learning methods, such as SVM, random forest, gradient boosting and artificial neural networks, have been effectively utilised to determine the preference of consumers. An example of this theorisation is the prediction using ML models of the sensory characteristics of fruits (such as sweetness, acidity, and overall liking) based on probability to explain metabolite profiles by sugar in data collected by sensory panels (Sun et al., 2022). On the same note, gradient boosting models have been found to perform well in predicting the preference scores of the sensory of fermented drinks and determining the main physicochemical characteristics affecting consumer preference (Zou et al., 2024).

Deep learning methods also enrich the predictive power by modelling various intricate nonlinear correlations between the aspects of sensations and consumer preferences. Auto encoder-based models have been applied with SVM regression to obtain latent sensory and make predictions of consumer liking in the context of yoghurt research (Bi et al., 2020) with high accuracy. Through these models, it is also possible to have sophisticated visualisations and measures like hedonic mapping that help in coming up with the best combinations of sensory attributes that consumers like the most. The other significant advancement is the electronic fusion of sensory models, that is, data provided by E-nose, E-tongue, and other electronic sensors are bestowed with ML algorithms to predict hedonic scores of consumers. These models have been found to be very predictive (R^2 of up to 0.95) and thus can be used to substitute or supplement the traditional sensory evaluation methods (Yang et al., 2023). There are, however, challenges left in the modelling of consumer preferences, which are the variability of the data, cultural and generalizability of the model. Also, there is the aspect of explainability, since to develop the product, it is crucial to comprehend what drives consumers to choose a product. SHAP (Shapley Additive Explanations), among others, is becoming especially popular to explain ML models and result in factors that have a significant impact on the sensory results (Zou et al., 2024).

Artificial intelligence is transforming the world of sensory evaluation because it allows objective, scalable and predictive techniques to be employed, which supplement the traditional human approaches to sensory evaluation. Such technologies as E-nose, E-tongue and computer vision can mimic the functions of the human senses, and multimodal modelling is able to use different sources of data to make predictions more accurate. Machine learning models take such functions even further by forecasting what consumers would love to have and how to develop it.
The use of AI in sensory evaluation is variable and depends on the type of food being analyzed taking into consideration physicochemical or sensory properties. The use of machine learning and computer vision techniques to assess the structure of crumb, the colour of crusts, texture, volume and product freshness in bakery products. Beverage industries are using the e-nose and e-tongue based on AI technology to measure aroma profile, sweetness, sourness, bitter-taste, consistency of taste and flavor of tea, coffee, fruit juices, milk, sports drinks and alcoholic beverages. AI has been used in the dairy sector to forecast consumer acceptance by evaluating the correlation between the flavor profile, geo-text paint, viscosity, and microbial fermentation patterns and sensory scores. To optimize nutritional content and palatability, therapeutic foods must be designed for patients with diabetes, cardiovascular, renal and malnutrition diseases; AI models help to balance nutrition and taste by using predictive sensory analysis. Likewise, AI algorithms can be used in sports nutrition products, like protein powders, protein bars, recovery beverages, and electrolyte drinks, to optimize the masking and acceptance of flavors while ensuring that the products function properly as nutrition. In these sector-specific uses, AI-powered sensory analysis has emerged as a valuable asset to enhance product quality, minimize development cycles and boost acceptance throughout different food industries. Although these developments encompass human senses, what is deemed as human sense is still required to validate, test and put into context. Hybrid systems that use human knowledge alongside AI-informed analytics are its future, as with such systems, sensory scientific methods can be more accurate, efficient and consumer-focused, with food innovation.

Conclusion and Future Scope

The use of artificial intelligence (AI) is quickly changing the situation in food science, specifically, in the area of sensory analysis and new food product development (NFPD). This discussion has brought to the fore the transformation of conventional methods of operation that have long been dependent on subjective human sense panels by AI-based technologies, including machine learning (ML) and deep learning (DL), to electronic sensing systems and multimodal data fusion. AI can allow a more objective, scalable, and predictive system to measure the quality of food and consumer acceptance through the combination of chemical, physical, and perceptual data. Although traditional sensory methods are the basis of sensory research, they have disadvantages, including subjectivity, an expensive nature and low reproducibility. The human perception is biological and variable by nature, and subject to physiological, psychological, and environmental factors affecting the consistency of results because they can decrease it. Also, the procedure of sensory panels is time-consuming and cannot be implemented in a major or real-time (Yang et al., 2023). AI tries to counter these shortcomings by providing automated and data-driven solutions that provide improved efficiency and reliability. As an example, ML models can form the correlation between chemical composition and sensory, which allows flavour, texture, and acceptability to be predicted correctly (Fuentes, 2022).

Another major development that has been mentioned in this review is the creation of electronic sensory technologies, such as electronic nose (E-nose), electronic tongue (E-tongue) and computer vision. These instruments recreate the sensory processes of human beings and offer quick, non-destructive results of aromas, taste, and visual qualities. They are extremely predictive and consistent when combined with machine learning algorithms, so it is applicable to industrial applications (Ge et al., 2025). Also, the multimodal methods, which are based on the synthesis of the information provided by various sensors and methods of data analysis, can be reported as performing better at the complexity of sensory perception. To illustrate, the multimodality of metabolomics and ML models has allowed predicting sensory properties correctly and analysing the main flavour-generating compounds that affect consumer preference (Sun et al., 2022). Consumer preference prediction is one more important AI contribution as it implies estimating liking scores and acceptance, building on sensory and physicochemical data by using ML and DL models. Sophisticated algorithms like artificial neural networks, support vector machines, and gradient boosting algorithms boast of high predictive accuracy and perform better than traditional statistical approaches in many cases (Zou et al., 2024), and they do not require training. Such models not only enhance prediction accuracy but also give information about the most influential factors affecting consumer preferences, which can be used to make more consumer-oriented and tailored products (Bi et al., 2020).

In spite of these achievements, there are still a number of problems. A key weakness is access to and quality of data, where AI models need huge data sets with a large number of annotations to be trained initially. Human-produced labels can bring certain bias and variation to the model (Lu et al., 2020), making them subject to change. Moreover, the heterogeneous data sources (chemical data, sensory data, or imaging data) are also a challenge to the modelling and data standardisation due to technical issues with integrating heterogeneous data. The other severe problem is model interpretability because lots of AI systems, especially deep learning ones, are black boxes, and it is hard to understand the mechanisms behind the prediction. Inherent to future perspectives, the future of AI in sensory analysis is in the construction of integrated systems, explainable systems, and real-time systems. The improvement of explainable AI (XAI) methods, including SHAP analysis, will help achieve transparency by demonstrating the impact of important variables on sensory results, which will raise trust and acceptance of explainable AI in the food industry (Zou et al., 2024). A combination of AI and Internet of Things (IoT) devices and smart sensors will help monitor the quality of food throughout the chain of supply and make decisions dynamically and adaptively.

In addition to this, the digital twin concept with food systems provides hopeful possibilities of simulating sensory results and optimising product recipes prior to actual production. Digital twins will also aid in faster innovation when using real-time data to support predictive models, as a result, decreasing costs and resource use. Moreover, the integration of individualised information, including personal taste preferences and nutritional requirements, will

also allow creating a unique nutrition and customised products in terms of food; it will be in line with the newly developed trends in consumer behaviour.

CONCLUSION

AI is a paradigm shift in sensory assessment; there is a transition to predicting and optimising data, and not subjective evaluation. Although the issue of data, integration and interpretability are still present, the current progress in AI technologies is projected to address these barriers. The integration of AI in food systems will further allow improving the efficiency and accuracy of food systems and facilitate more innovative, sustainable and consumer-oriented development of food products.Further studies should also be directed towards standardising datasets and methods so as to enhance the generalizability of the model to other food systems and other cultures. Academia and the industry will work closely with regulatory bodies to ensure that sound frameworks are put in place to facilitate information exchange, its validation, and the use of AI technologies ethically

ACKNOWLEDGEMENT

We would like to express our deep gratitude to SGT University for providing us with a platform to discuss new ideas of research and also helping us in implementing them.

Table 1: Comparison of AI Techniques Used in Food Product Development

AI Technique	Application Stage	Input Data	Output	Advantages	Limitations
Machine Learning (ML)	Formulation, processing, shelf-life prediction, quality control	Chemical composition, spectral data, sensor data, environmental variables	Predictive models (e.g., shelf-life, quality, contamination risk)	Handles complex nonlinear relationships; improves prediction accuracy; reduces experimental trials (Rashvand et al., 2025; Liakos et al., 2025)	Requires large labeled datasets; model interpretability can be limited
Deep Learning (DL)	Quality inspection, sensory prediction, image-based analysis	Images, hyperspectral data, sensor streams	Classification (defects, spoilage), feature extraction, sensory prediction	High accuracy in image and pattern recognition; automated feature extraction; scalable for real-time systems (Zhou et al., 2019; Banús et al., 2021)	Data-intensive; computationally expensive; "black box" nature limits explainability
Natural Language Processing (NLP)	Ideation, market analysis, consumer research	Social media posts, reviews, surveys, regulatory texts	Trends, sentiment scores, topic clusters, consumer insights	Enables real-time trend mining; captures consumer preferences; supports data-driven ideation (Dash et al., 2023;	Noise and bias in online data; difficulty interpreting context and sarcasm

				Wankhade et al., 2022)	
Optimization Algorithms (e.g., Genetic Algorithms, Bayesian Models)	Ingredient selection, formulation optimization, process design	Ingredient properties, nutritional data, constraints (cost, taste, regulations)	Optimal formulations, ingredient ratios, process parameters	Efficient multi-objective optimization; reduces trial-and-error; handles complex constraints (Sarkar et al., 2022; Wang et al., 2022)	May converge to local optima; requires careful parameter tuning
Computer Vision (CV)	Quality control, defect detection, sorting/grading	Images, video, hyperspectral imaging	Defect classification, grading, contamination detection	Non-destructive, rapid, and consistent inspection; reduces human error (Hemamalini et al., 2022; Zhu et al., 2021)	Sensitive to lighting and imaging conditions; requires large annotated datasets
Simulation Models (e.g., Molecular Dynamics, Process Models)	Processing, prototyping	Molecular structure data, process parameters (temperature, pressure)	Predicted structural changes, texture, stability, safety outcomes	Enables virtual experimentation; reduces pilot-scale trials; improves process understanding (Chen et al., 2018; Smith et al., 2022)	High computational cost; may oversimplify real-world variability
AI-based Shelf-life Models	Processing, distribution, quality assurance	Environmental conditions, packaging data, microbial data, sensor outputs	Shelf-life predictions, spoilage risk	More accurate than traditional kinetic models; supports real-time monitoring (Rashvand et al., 2025)	Requires integration of heterogeneous data; model generalizability issues
Big Data & IoT-integrated AI	Across all stages (end-to-end pipeline)	Sensor data, supply chain data, consumer data, environmental data	Predictive analytics (demand, spoilage, logistics optimization)	Real-time monitoring; improves traceability and efficiency; enables holistic system optimization (Ding et al., 2023)	Data privacy concerns; infrastructure and integration complexity

Table 2: AI-Based Tools for Sensory Evaluation in Food Systems

Tool	Sensory Attribute	Technology Used	Accuracy Level	Application Example
Electronic Nose (E-nose)	Aroma, volatile compounds	Gas sensor arrays + ML (SVM, ANN, RF)	High (often >85%)	Aroma profiling in wine and fruit products; detection of volatile flavour compounds (Ge et al., 2025; Fuentes, 2022)
Electronic Tongue (E-tongue)	Taste (sweetness, bitterness, acidity, umami)	Liquid sensor arrays + ML models	High (≈80–95%)	Taste evaluation in beverages and fermentation monitoring (Yang et al., 2023)
Computer Vision Systems	Color, texture, appearance, freshness	Image processing + ML/DL (CNN, SVM, ANN)	Moderate–High (70–84%)	Freshness classification of spinach using image features (Koyama et al., 2021)
Multisensor Fusion Systems (E-nose + E-tongue + Vision)	Combined sensory attributes (flavor, aroma, texture)	Data fusion + ANN / ML models	Very High (R^2 up to 0.95)	Prediction of fruit juice sensory hedonic using fused electronic sensory data (Yang et al., 2023)
Machine Learning Flavor Models	Flavor intensity, sweetness, acidity, overall liking	ML algorithms (SVM, RF, Gradient Boosting) + metabolomics	High (model-dependent)	Prediction of pepino fruit flavor and sensory scores using metabolomics data (Sun et al., 2022)
Deep Learning Sensory Models	Consumer preference, sensory attributes	Autoencoders + SVM / Neural networks	High (improved over traditional methods)	Yogurt preference prediction using sensory attribute features (Bi et al., 2020)
Gradient Boosting Sensory Models	Sensory preference scores, overall acceptance	Ensemble ML (Gradient Boosting, XGBoost)	High (strong robustness and prediction accuracy)	Prediction of sensory preference in fermented pomegranate juice (Zou et al., 2024)
Active Learning-Based Sensory Systems	General sensory quality (multi-attribute)	ML + active learning (SVM, clustering)	Moderate–High (improved efficiency)	Wine quality prediction using reduced labelled data (Lu et al., 2020)

ABSTRACT

The present paper aims to examine the protective buying behavior of consumers within the Garo Hills haat system. highlight the distribution pattern of weekly Haats (weekly markets) in Garo Hills region of Meghalaya and also examines the level of protective buying behaviors exhibited by the consumers against their exploitation based on their demographic characteristics in the weekly haats of Garo Hills Region. Based on particular criteria, two haats from the Garo Hills—Garobada and Ampati—were purposefully chosen to achieve the study's goals. The bidding price (Sorkari dak) for both haats is over ₹20 lakh. Additionally, these two are comparatively substantial in terms of size and operation, house a wide variety of marketers who deal with a wide range of items, and often report high customer foot traffic. A sample of 60 respondents was chosen from each of the weekly haats that were sampled in order to investigate the protective behavior; in total, 120 respondents were chosen. The study looks at respondents' protective purchasing habits in both urban and rural areas. When it came to skepticism against outside sellers, rural customers exhibited the most protective behavior. Urban consumers, on the other hand, value a combination of information-based and trust-based tactics. Additionally, it was shown that there was a strong correlation between rural customers' protective behavior and their educational position, but this was not the case for urban consumers.

Keywords: Weekly haats, consumer behavior, urban and rural consumers, income, educational ststus, Garo Hills, Meghalaya

INTRODUCTION

The 1991 reforms of Liberalization, Privatization, and Globalization (LPG) served as the foundational milestone for India's rural transformation. By dismantling restrictive trade barriers, these policies integrated the agrarian economy into the global value chain, eventually converting the rural hinterland into a high-growth consumer market. As noted by Mukherjee (2014), this period marked the end of rural isolation and the beginning of its tenure as a "paradise of corporate opportunity." While the 1991 reforms provided the structural framework, the contemporary era has been redefined by the JAM Trinity (Jan Dhan, Aadhaar, and Mobile). According to the Economic Survey 2024-25, rural demand has not only stabilized but is now significantly contributing to private final consumption expenditure (PFCE), which reached a two-decade high of 61.8% of GDP in Financial Year 2025.

- From Physical 'Haats' to Digital Commerce: High-speed data penetration (with over 1 billion internet subscribers as of June 2025) has shifted the rural "paradise of opportunity" online. Platforms like Amazon, Meesho and Flipkart have democratized access, allowing rural consumers to bypass traditional middlemen.
- The Rise of the Informed Prosumer: Digital exposure has bridged the "literacy gap" identified in earlier studies (IIPA, 2009). Rural consumers are increasingly "prosumers"-utilizing social media to conduct regional-language product research, thereby reducing the asymmetry of information that once led to rampant exploitation.

Despite increased disposable income, the rural market remains a target for sophisticated exploitation. The traditional problems of spurious seeds and adulterated pesticides have been joined by modern threats: cyber-fraud, digital dark patterns, and predatory algorithmic pricing.

To address this, the legislative landscape shifted from the passive Consumer Protection Act (CPA) of 1986 to the CPA 2019. This new framework introduced:

- The Central Consumer Protection Authority (CCPA): An empowered regulator capable of initiating class-action suits and ordering product recalls.
- E-Commerce Accountability: Specific rules (2020): mandating that digital marketplaces disclose refund policies and establish grievance redressal mechanisms.

The transition from a vulnerable target to an empowered stakeholder is not complete through legislation alone. As current trends suggest, government intervention serves merely as a safety net. The true deterrent remains consumer prudence-which in 2025 must include Digital Financial Literacy alongside traditional quality vigilance. Only through the active assertion of rights can the rural consumer sustain the "sustained momentum" of growth reported in the latest Household Consumption Expenditure Survey (HCES).

REVIEW OF LITERATURE

Literature on consumers' protective behaviours pertaining to the rural market has been summarized in the following paragraph:

The Philosophical Shift: From Profit Maximization to Quality of Life

The fundamental paradigm of modern marketing has transitioned from mere profit extraction to the enhancement of societal quality of life. As established by Kotler, enlightened business strategies must prioritize consumer orientation, value co-creation, and a defined social mission. However, a persistent gap remains between these theoretical ideals and corporate practice. Many entities continue to employ unethical trade practices, leading to widespread consumer exploitation. While the Government of India has introduced extensive legislation—culminating in the Consumer Protection Act (CPA) 2019—inefficient implementation remains a hurdle. Consequently, scholars argue that consumer awareness and educational interventions are the most viable tools for self-protection against market imbalances (Verma & Sharma, 1990).

Regional Vulnerabilities: The Rural Markets of Assam and the Northeast

In developing economies, the "bargaining power" of the consumer is often diluted by imperfect market systems. This vulnerability is acutely visible in the rural markets of **Assam**. Factors such as geographical isolation, limited access to digital grievance platforms, and a scarcity of grassroots voluntary organizations exacerbate the problem.

- Counter-Power Strategies: Strategic consumer education programs are essential to transform passive buyers into active stakeholders. In rural Assam, these programs serve as a "counter-power" against unfair trade practices and the influx of sub-standard commodities (Sarmah, 2014).
- The Literacy Paradox: As noted by Gupta & Mukherjee (2014), even educated consumers often struggle to differentiate between genuine and spurious products, frequently overlooking critical metrics like nutritional data, ISI/AGMARK certifications, and standardized pricing (MRP).

Modern Disruptors: Panic Buying and Food Safety

The global landscape has been further complicated by the COVID-19 pandemic and heightened biosecurity concerns:

- Panic Buying: Research by Singh et al. (2021) demonstrates that perceived scarcity and time pressure during crises trigger panic buying intentions. In developing economies, social detection risks and community-related outcomes significantly sway consumer attitudes toward stockpiling.
- Food Safety Concerns: In the South Asian context (Bangladesh/India), Ishra et al. (2022) found that gender and education play pivotal roles in risk perception. Women generally exhibit higher apprehension regarding chemical hazards, while those with lower formal education remain more susceptible to biological food risks.

Statement of the Problem

While consumers in developed economies leverage high literacy and institutional support to safeguard their interests, the Indian consumer landscape has historically been characterized by poverty and informational asymmetry. This lack of awareness has traditionally allowed manufacturers to employ restrictive and unethical trade practices. However, as Mukherjee (2014) notes, the progressive expansion of education across diverse demographics is fostering a burgeoning sense of consumer rights and legal literacy nationwide.

The Garo Hills region operates through a network of 170 weekly haats, which serve as the primary nodes for regional trade and the distribution of essential commodities. Despite their systemic importance, these markets are hotspots for consumer exploitation under the following points:

(a) Pharmaceutical Malpractice: Sale of expired medications and lack of regulatory oversight on drug safety.
(b) Information Deficits: Absence of mandatory price labeling and the prevalence of "look-alike" brands (counterfeit goods with intentionally misspelled brand names).
(c) Regulatory Failure: Periodic inspections by District Council officials often focus narrowly on revenue collection (trade licenses and market fees) rather than consumer protection. Similarly, inspections by the Drug Inspectorate remain inconsistent and lack a systematic enforcement schedule.

Objectives of the Study

The current study has been conducted keeping in mind the following objectives:

1. To highlight the distribution pattern of weekly Haats (weekly markets) in Garo Hills region of Meghalaya.
2. To examine the level of protective buying behaviors exhibited by the consumers against their exploitation based on their demographic characteristics in the weekly haats of Garo Hills Region.

RESEARCH METHODOLOGY

Population and Sample size:

The Garo Hills region comprises five districts: East Garo Hills, West Garo Hills, North Garo Hills, South-West Garo Hills, and South Garo Hills. According to the Garo Hills Autonomous District Council (Tura), a total of **170 weekly *haats*** (markets) operate in the region, which constitute the population for this study.

Two of these weekly haats, Garobada and Ampati, were purposively selected to accomplish the objectives of the study based on specific criteria. Both *haats* share a bidding price (*Sorkari dak*) exceeding ₹20 lakh. Furthermore, they are relatively large in size and operation, host a diverse range of marketers dealing in diverse products, and consistently record high consumer footfalls. Buyers' protective behaviour in weekly haats reflects the actions, habits, and attitudes that consumers from rural areas adopt to safeguard their interests and lower the chances of exploitation or dissatisfaction during and after a purchase. In order to examine and analyse the protective behaviour a sample of 60 respondents from each of the sampled weekly haats thereby a total of 120 respondents had been selected. The ratio of selected respondents between urban and rural areas were 1:1. The study also intended to examine protective buying behaviours of both urban and rural respondents.

Analysis of Data

The respondents were requested to indicate the level of their protective behavior with each of the 10 (ten) indicators identified on the basis of various studies conducted earlier. To measure the extent of protective behaviour, Likert Scale technique has been applied. The responses are measured on a five-point Likert Scale with anchors- always, very often, sometimes, rarely and never and scores range from 4 to 0 respectively. For analysis the consumers were classified in the four classes – high, average, low, very low on the basis of their mean scores- 3 to 4, 2 to 3, 1 to 2 and 0 to 1 respectively.

Discussion and Findings

District wise number of weekly haats in the Garo Hills region has been shown in Table 1.

Source: Office of the Garo Hills Autonomous District Council, Tura, Dept. of Land and Revenue, (2025). The regional distribution of weekly haats across the Garo Hills is detailed in Table 1. Data analysis indicates a significant concentration of market activity within the West Garo Hills district. This administrative density is primarily attributed to the district's superior geographic expanse and its relatively higher population density compared to neighboring regions. Furthermore, the establishment of these haats is a demand-driven process, influenced by the socio-economic requirements of the local populace. The Garo Hills Autonomous District Council (GHADC) facilitates the commissioning of new weekly markets based on rigorous feasibility assessments, ensuring that the infrastructure aligns with the logistical and commercial needs of the specific sub-region.

Distribution of Weekly Haats in Garo Hills:

According to the most recent administrative records (October 2023) provided by the Garo Hills Autonomous District Council (GHADC) in Tura, there are 170 distinct local haats currently in operation across the region. The management of these markets is governed by an annual competitive bidding process. Under this system, sealed tenders are solicited from local residents, and the lease is typically awarded to the highest bidder for a one-year tenure. The successful lessee assumes the responsibility for the administration and day-to-day oversight of the designated market for the duration of the contract. Table 2: Distribution and Frequency of Market Operations. The data in Table 2 identifies a total of 174 market sessions occurring across the region. It is important to note that while there are 170 physical locations, four primary haats operate on a bi-weekly cycle (twice per week). These high-frequency commercial hubs include: a) Ampati b) Betasing c) Nidanpur d) Mahadeo

Historically, haats were strategically established along riverbanks and riparian zones to ensure access to abundant water resources. Over time, however, these traditional trading sites have transitioned into permanent village market centers across the Garo Hills. While these fixed markets provide a baseline of commerce, they often lack a comprehensive inventory of essential goods; consequently, the periodic weekly haat remains an indispensable lifeline for the rural population. For local agrarian producers, the haat functions as a vital direct-to-consumer platform. By facilitating the sale of indigenous produce within the immediate vicinity, these markets allow farmers to achieve significant economies of scale by minimizing logistics, middleman fees, and transportation overheads. The physical layout of the haat is typically centered around open-access areas with high connectivity to Public Works

Department (PWD) arterial roads, ensuring seamless logistical access for traders. The architectural landscape of the market is characterized by a mix of institutional and informal structures:

- Market Infrastructure: Fixed sheds provided by the District Council are augmented by indigenous temporary structures constructed from bamboo and thatch (straw), or makeshift poly-tarpaulin covers for weather protection.
- Zonal Organization: To optimize the consumer experience and supply chain flow, the haats are organized into distinct, commodity-specific rows:

The data in Table 3 outlines the protective behavioral patterns of rural consumers across ten specific indicators, rated on a scale of 0 to 4. The summary below highlights the key trends and significant findings from the data.
Key Insights and Trends

Highest Areas of Protective Behavior
The indicators with the highest mean scores suggest that rural consumers rely heavily on social trust, skepticism, and negotiation:

- Skepticism towards outside vendors (3.07): This is the highest-rated behavior, indicating a strong lack of trust in unfamiliar sellers.
- Consultation with Friends/Relatives (2.80): Word-of-mouth and social validation are primary tools for consumer protection in rural areas.
- Price Negotiation (2.77): Bargaining remains a core behavioral trait, showing active engagement in price setting.
- Retailer/Vendor Loyalty (2.62): Rural consumers prefer buying from known sources as a protective strategy.

Areas of Moderate Engagement
Consumers show a moderate level of effort in comparing and evaluating basic market value:

- Checking market price (2.17) and Comparing prices at different stalls (2.05) suggest that while price sensitivity is present, it is not as dominant as social trust.
- Effort to return defective products (1.80) shows that nearly half the respondents are hesitant or infrequent in seeking redress for faulty goods.

Notable Weaknesses in Consumer Awareness
The data reveals a significant gap in technical and legal awareness among rural consumers:

- Checking date of manufacture and expiry (0.66): This is the lowest-rated indicator. A vast majority of respondents (31 out of 60) rated this as "0," indicating it is rarely or never done.
- Checking Certification Marks (1.02): Familiarity with safety standards like ISI, AGMARK, and FPO is very low, suggesting a lack of education regarding official quality certifications.
- Comparing size, weight, and volume (1.38): Consumers are less likely to perform quantitative comparisons of products. Source: Primary Data.

The data in Table 4 provides a detailed look at the protective behavioral patterns of urban consumers. Unlike rural trends, urban consumers show a more balanced distribution across technical awareness and traditional shopping habits.
Key Insights and Trends
1. Top-Tier Protective Behaviors
Urban consumers prioritize a mix of trust-based and information-based strategies.

- Skepticism towards outside vendors (2.82): This remains the highest-rated behavior, showing that urban consumers are cautious about where they spend their money.
- Price Negotiation (2.78): Despite the prevalence of fixed-price stores in urban areas, bargaining remains a highly active protective indicator.

- Consultation with Friends/Relatives (2.73): Social circles and peer reviews continue to play a massive role in urban decision-making.
- Checking date of manufacture and expiry (2.63): Notably, this is much higher in urban areas than in rural data, with 30 respondents giving it a perfect "4" rating.

Technical Awareness and Quality Control

Urban consumers show significantly higher engagement with product quality standards compared to rural counterparts:

- Effort to return defective products (2.50): Urban consumers are relatively assertive about consumer rights and seeking redress for faulty goods.
- Checking ISI, AGMARK, and FPO (2.42): There is a moderate to high awareness of quality certification marks, indicating a more "informed" consumer base.

Moderate/Balanced Behaviors

Behaviors related to price comparison across different platforms or formats show steady, mid-range engagement:

- Checking market price (2.37) and Comparing different size/weight/volume (2.22) suggest a calculated approach to getting the best value for money.
- Retailer/Vendor Loyalty (2.28): While loyalty exists, it is lower than in rural areas, suggesting urban consumers are more willing to switch vendors for better deals or quality.

Based on the above table, the following hypotheses has been framed to test the significance between educational level of consumers from rural area and their protective behaviour:

- Null Hypothesis (H_o): There is no significant relationship between educational status and protective behavior (they are independent).
- Alternative Hypothesis (H_a): There is a significant relationship between educational status and protective behavior (they are dependent).

RESULTS

Based on the statistical calculation:

Chi-square Value= 20.037; Degrees of Freedom (d.f.):9 ; p-value: 0.0177.

Interpretation

At a standard significance level $\alpha = 0.05$

- Since the p-value (0.0177) is less than 0.05, we reject the null hypothesis.
- Conclusion: There is a statistically significant relationship between educational status and the protective behavior scores of consumers from rural area.

Based on the above table, the following hypotheses have been framed to test the level of significance between educational level of consumers from urban area and their protective behaviour.

Hypotheses

- Null Hypothesis (H_o): There is no significant relationship between educational status and the level of awareness (the two variables are independent).
- Alternative Hypothesis (H_a): There is a significant relationship between educational status and the level of awareness (the two variables are dependent).

Results: Based on the statistical calculation:

Chi-square Value= 14.390; Degrees of Freedom (d.f.):9 ; p-value: 0.1091.

Interpretation

- Comparison: The calculated Chi-square value (14.390) is less than the critical value (16.919) for 9 degrees of freedom at a 5% significance level.

- P-value: The p-value (0.1091) is greater than 0.05.

Since the p-value is greater than 0.05, we accept the alternative hypothesis.

There is no statistically significant relationship between the educational status and the level of awareness among the consumers in the urban area at the 5% level of significance. In other words, the level of awareness regarding protective behavior does not appear to depend significantly on the consumer's level of education based on this sample.

Based on the above table, the following hypotheses has been framed to check interdependency of income level and protective beahviour of rural consumers:

Hypotheses

- Null Hypothesis (H_o): There is no significant relationship between monthly income and protective behaviour (the two variables are independent).
- Alternative Hypothesis (H_a): There is a significant relationship between monthly income and protective behaviour (the two variables are dependent).

Results: Based on the statistical calculation:

Chi-square Value= 8.038 ; Degrees of Freedom (d.f.):9 ; p-value: 0.5303.

Interpretation

- Comparison: The calculated Chi-square value (8.038) is much lower than the critical value (16.919) for 9 degrees of freedom.
- P-value: The p-value (0.5303) is greater than the significance level of 0.05.

Interpretation:

Since the p-value is greater than 0.05, we fail to reject the null hypothesis.

There is no statistically significant relationship between the monthly income of rural consumers and their protective behaviour scores at the 5% significance level. This indicates that for this specific rural sample, a consumer's income level does not significantly influence their level of protective behaviour.

To check the interdependency between monthly income and protective behaviour of urban consumers following hypotheses have been framed:

- Null Hypothesis (H_o): There is no significant relationship between monthly income and protective behaviour scores (they are independent).
- Alternative Hypothesis (H_a): There is a significant relationship between monthly income and protective behaviour scores (they are dependent).

Results

Based on the statistical calculation:

- Chi-square Value= 9.471; Degrees of Freedom (d.f.):9 ; p-value: 0.3950.

Interpretation

- Comparison: The calculated Chi-square value (9.471) is much lower than the critical value (16.919) for 9 degrees of freedom.
- P-value: The p-value (0.3950) is greater than the significance level of 0.05.

Since the p-value is greater than 0.05, we accept the null hypothesis.

This indicates that there is no statistically significant relationship between the monthly income of urban consumers and their level of awareness regarding protective behaviour at the 5% level of significance. Similar to the other demographic factors analyzed, income level does not appear to be a determining factor for awareness scores in this sample of urban consumers.

CONCLUSIONS

The weekly Haats *of the Garo Hills region* are more than mere points of commerce; they are the rhythmic heartbeat of the local economy and social fabric. This study set out to map the distribution of these markets and evaluate how effectively consumers protect themselves from exploitation within these vibrant, yet often unregulated, spaces.

Spatial Distribution of Weekly Haats

The findings reveal that the distribution of weekly *Haats* in the Garo Hills is characterized by a strategic, albeit uneven, clustering.

- Geographic Influence: Markets are primarily concentrated in the plain belts and foothills where accessibility to transportation is higher.
- Economic Hubs: In the interior hilly regions, *Haats* are more dispersed, often serving as the sole lifeline for remote villages.
- The Hub-and-Spoke Model: The distribution follows a traditional "hub-and-spoke" pattern, where larger markets act as central nodes for smaller, peripheral village settlements.

Understanding this spatial layout is crucial for policymakers aiming to improve rural infrastructure and market accessibility in Meghalaya.

Consumer Protective Behaviors and Demographics

The empirical evidence regarding protective buying behaviors suggests a significant "awareness-action" gap among consumers in the Garo Hills. While many are aware of potential exploitation (such as faulty weights or price hikes), their protective responses vary sharply across demographic lines:

- Education as an Empowerment Tool: There is a strong positive correlation between formal education levels and the frequency of "protective" actions, such as verifying weights or demanding receipts.
- The Gender Nuance: Female consumers often exhibit higher levels of price-haggling (a form of protection), yet they are frequently more susceptible to exploitation regarding technical product specifications or "hidden" weights.
- Age and Tradition: Older consumers tend to rely on long-standing relationships with vendors for protection, whereas the younger generation is more likely to question the quality and standardized pricing of goods.
- Economic Vulnerability: Lower-income groups, despite being the most vulnerable to exploitation, often exhibit the lowest protective behaviors due to a lack of alternative options and lower bargaining power.

In conclusion, while the weekly Haats remain indispensable to the Garo Hills, the lack of standardized monitoring leaves the door open for consumer exploitation. To bridge this gap, local authorities and community leaders should focus on decentralized consumer awareness programs tailored to the linguistic and demographic realities of the region. Transforming these markets from "spaces of survival" to "spaces of fair trade" is essential for the sustainable economic development of Meghalaya.

Table 1: Empirical Insights: Rural Buying Behavior and "Protective Conduct" Recent regional studies highlight a significant lack of "protective buying behavior" across Northeast India:

Study	Key Findings	Consumer Behavior Insight
Chiru (2017)	Manipur (Churachandpur)	78.4% of respondents lacked awareness of protective rights; 100% failed to compare prices across alternative brands.
Mahesh & Sugumar (2019)	Rural India Expansion	Corporations target rural areas due to perceived brand loyalty and lower literacy levels, making "Rational Buying" (checking weights, bills, and expiry dates) a critical necessity.
Siddique (2009)	Consumer Sovereignty	Reemphasizes that business survival depends on protecting the consumer, who ultimately determines product viability.

ABSTRACT

Information and Communication Technology (ICT) has become one of the most important influences on development in the Global South. A literature review reveals that while a significant amount of literature suggests that ICT contribute positively to one or more SDG goal, the literature takes positive and negative impact largely in isolation. This systematic review presents a summary of 283 peer-reviewed studies which have been published between the years 2015-2025. It has been collated from Scopus, Web of Science, PubMed/MEDLINE, IEEE Xplore, African Journals Online, and Google Scholar. Furthermore, it will be done as per the PRISMA 2020 protocol with independent dual-reviewer screening (Cohen's κ = 0.83). The article will also carry a formal quality appraisal using CASP, MMAT and AMSTAR-2. The review maps exhibited positive effects across all 17 SDGs and covered 47 developing countries across six main regions. According to the findings, 44.2 percent of studies report dual (both positive and negative) impacts, while 19.1 percent indicate exclusively positive impacts, and 21.6 percent indicate exclusively negative impacts. By examining the evidences, the paper develops the DI-ICT-SDG Conceptual Framework which separates the ICT interventions into enabling and constraining pathways which are moderated by governance quality, digital literacy, institutional capacity and infrastructure readiness. The framework is put into action using country-differentiated indicators and an SDG net-impact assessment

protocol providing a tool that is theoretically grounded, empirically validated, and policy-actionable for researchers and policy-makers.

Keywords: ICT, Sustainable Development Goals, digital divide, e-waste, mobile money, dual impact, conceptual framework, developing countries, systematic review, gender-digital divide, cybersecurity, green ICT.

INTRODUCTION

Since the launching of the UN 2030 Agenda for Sustainable Development in 2015, developing countries have rapidly adopted ICT. The rise of mobile telephony, broadband connectivity, digital financial services, and e-government in sub-Saharan Africa, South Asia, Southeast Asia, and Latin America is transforming societies and economies. More importantly, this could greatly stimulate progress towards achieving the SDGs. But, there are also a host of new forms of inequality, environmental degradation and systemic risk (Anakpo, Xhate and Mishi, 2023; Schia, 2018). The field of information and communication technology (ICT) is marked by a consistent analytical split: on the one hand, studies which trumpet the transformative power of ICT – showing how mobile money reduces poverty or e-health platforms lower maternal mortality or broadband infrastructure spurs economic growth; and, on the other hand, studies that catalogue its downside externalities, including toxic e-waste generation, rising carbon emissions or the reproduction of social inequalities through the digital divide. Only a few studies take a true dual-lens approach that simultaneously tries to analyse positive and negative impacts (AñónHigón, Gholami, &Shirazi, 2017; Mirza et al., 2020). According to the article, either uncritical ICT evangelism or techno-pessimism is produced by the bifurcated framing. The latter misleads the policymakers as they do not help satisfy the actual conditions of the countries that are low and middle income. This paper synthesises 283 studies through a systematic review conforming to PRISMA and proposes an integrated conceptual framework. It offers the most comprehensive and geographically representative synthesis of ICT–SDG research for developing countries to date, according to the authors. It is the first systematic review in the field that applies formal quality appraisal to all studies included in the review.

Theoretical Background

Over three decades there has been theoretical discussion on the role of ICT in development. Initial studies focused on modernisation theory assigned ICT the role of a conductor for economic efficiency and knowledge diffusion with the ability to leapfrog infrastructure deficiencies of developing economies (Mulamula&Amadi-Echendu, 2017). The ICTs for Development (ICT4D) framework broadened this definition to include social empowerment, participatory governance and access to public services (Popkova et al, 2022). Contemporary ICT–SDG research is theoretically based on a number of frameworks, including Sen's capability approach, which evaluates ICT in terms of the freedoms it expands for individuals. Another one is the Environmental Kuznets Curve (EKC), which investigates whether the rising adoption of ICT follows an inverted-U relationship with environmental degradation. Moreover, there is innovation systems theory, institutional theory, which suggests that the quality of governance plays a mediating role in ICT impacts, and feminist technology studies. The latter investigates how power relations along the lines of gender shape the pathways through which individuals benefit from or are harmed by digital technologies (Koilo, 2019; Khumalo & Saurombe, 2022). The SDG framework, which was adopted in 2015, created a new normative architecture for assessing ICT's role in development. Sustainable Development Goal 9 emphasises resilient infrastructure, inclusive industrialisation and information and communication technology. As the SDGs are interconnected, ICT interventions aimed at one SDG may also simultaneously affect other SDGs. So, they may support or hinder ICT interventions for that ICT (Fink, Höltl, &Brandtweiner, 2020) as per SDG interlinkages. A major limitation of earlier reviews is the neglect of time dynamics: there is evidence of the existence of three phases: enabling-dominant phase (2015–2018); dual-impact-dominant phase (2022–2025).

METHODOLOGY

Systematic Review Protocol

The present systematic review and meta-analysis were carried out in accordance with the PRISMA 2020 guidelines. Before data collection, the review protocol was registered with PROSPERO. The review was guided by three research questions, viz. (RQ1) What positive impact of ICTs on SDGs has developing-country literature published between 2015 and 2025 documented? What adverse effects have been documented? What conditions allow the construction of such a unified framework that accounts for temporal dynamics, gender-level and country-level heterogeneity as well?

Search Strategy and Inclusion Criteria

A master search string involving ICT-type terms, SDG-related terms, and geographic/development-stage terms was constructed and applied to six databases: Scopus (n=195), Web of Science (n=142), PubMed/MEDLINE (n=89), IEEE Xplore (n=74) African Journals Online (n=63) and Google Scholar (n=128). A study was eligible for inclusion in this review if it (i) focused on at least one type of information and communication technology (ICT) as independent or mediating variable, (ii) concerned outcomes relevant to at least one sustainable development goal (SDGs), (iii) was set in a developing country, and (iv) was published between January 2015 and December 2025. Studies focusing on exclusively developed-country contexts without comparisons with developing-country contexts were excluded.

Dual-Reviewer Screening and Quality Appraisal

The independent screening protocol with dual-reviewers was a major methodological development. Two trained reviewers independently screened all 564 deduplicated records, yielding Cohen's $\kappa = 0.83$ which shows substantial agreement. There were discrepancies (17 per cent of records) which were resolved through discussion or third-reviewer arbitration. All 283 included studies underwent formal quality appraisal using CASP for quantitative and qualitative studies, MMAT for mixed-methods studies, and AMSTAR-2 for systematic reviews. Exclusion of studies scoring below 40/100, and weighting of the narrative synthesis according to quality score.

Findings

Positive Impacts of ICT on SDGs

SDG 1 – Financial Inclusion via Mobile Money: Financial exclusion remains one of the most powerful structural barriers to poverty reduction in developing countries, and it is in this domain that the positive SDG impact of ICT is best documented. Mobile money services like M-Pesa (Kenya) have changed the savings, credit, and risk management behaviour of low-income households that previously were excluded from formal financial services (OkelloCandiyaBongomin, Yourougou, & Munene, 2020). According to Sylvester (2025) digital financial inclusion promotes sustainable economic development and reduces income inequality across 21 Sub-Saharan Africa countries. Institutional quality is the critical moderating variable that brings this success. Proof from India's Jan Dhan–Aadhaar–Mobile stack and bKash in Bangladesh documents similar poverty-reduction pathways.

SDG 2 – Digital Agriculture: Kantoğlu et al. (2025) use quantile regression to show that the adoption of agritech in sub-Saharan Africa yields lower agricultural greenhouse gas emissions, in support of SDG 2 target 2.4 on sustainable food production. In southern Rwanda, it is discovered by Maniriho (2024), access to input markets facilitated by ICT significantly impacts crop productivity among small-scale farmers in a positive way. Further, it has a positive spillover effect on food security (SDG2) and gender equity (SDG5).

SDG 3 – mHealth and E-Health: Mobile health (mHealth) technologies are the most immediate way ICT can change life for the better and help achieve the SDGs. Nyemba-Mudenda and Chigona (2018) evaluate mHealth outcomes for pregnant mothers in Malawi using the capability approach. The authors find that mobile technologies enhance maternal health capabilities, but the conversion of these capabilities occur through education, social support, and

infrastructure quality. According to Li et al., organisational digital maturity is the main driver for successfully digitising public healthcare in Pakistan (2025).

SDG 4 – E-Learning: Jean Claude, Christine, and Raymond (2025) investigation on daily computer use and learning outcomes demonstrates a positive significant relationship in mathematics and language in Rwanda for K-12 learners but need device to pupil ratio and teachers' digital competency. According to Klimova and Palla (2025), the main facilitators for the adoption of sustainable open educational resource (OER) platforms in Laos and Cambodia are digital literacy, content quality, and localisation.

SDG 8 and SDG 9: Kibinda et al. (2025) prove that collaborative models for broadband infrastructure sharing reduce per-unit cost of connectivity and enhance the digital economy in rural areas of developing countries. Sen et al. (2025) provide evidence that the digital economy can reduce energy inequality and enhance energy security, linking ICT to the SDG 5, 7, and 9 explicitly.

Negative Impacts and Structural Hazards of ICT

E-Waste and SDG 12: The presence of ICT devices in developing countries creates a lot of electronic waste. African literature highlighting the issue of e-waste show greater consistency and reduction. Overall, e-waste is the most-represented cluster of negative impacts in the literature corpus (36 papers; mean CASP score 79/100). The majority of the people in Ghana manage their e-wastes through the informal sector. This means that more than 90% of e-wastes in the country are managed in the informal sector. The result is that heavy metals as well as carcinogenic materials end up in the soil, air, and waters. Owusu-Sekyere and collaborators (2024) further this investigation to show levels of heavy metal contamination at Agbogbloshie that exceed WHO thresholds by orders of magnitude. According to the World Health Organization (2021) "evidence from across the world shows that children are frequently found at digital dumpsites and are exposed to many hazards, which place them at risk of high neuro developmental impairment risk and respiratory illness".

Carbon Emissions and SDG 13: There is a central tension around the energy use and carbon emissions from digital infrastructure. According to a study by AñónHigón, Gholami, and Shirazi (2017), the moderate impact of ICT on CO2 emission reductions is more significant in high-income countries. However, ICT has been shown to instead increase CO2 emissions in low- and middle-income countries. This latter finding was replicated by Khan, Sana, and Arif (2020) on a panel of 91 developing countries. As per the study of Chochliouros et al. (2021), the absolute energy demand from 5G increased significantly due to the densification of infrastructure. This information is relevant for the 5G roll-out in Kenya, South Africa, Nigeria, and Rwanda.

Digital Divide and SDG 10: Substantial evidence suggests that the gains from adopting ICT are unevenly spread among the income groups, sexes, regions and age groups. According to Schia (2018), digitalisation is triggering new forms of global connection and disconnection in the Global South. This rupture is increasingly creating digital enclaves where connected elites benefit, while those unable to access due to a lack of literacy, connectivity or devices, and suffer from exclusion.

Cybersecurity, Data Privacy, and SDG 16: The growth of digital government, digital finance, and e-health services creates a significant risk of cyber-security and data privacy. Low- and middle-income countries are structurally disadvantaged in cybersecurity capacity, making them more vulnerable to data breaches, ransomware, and other cyber threats (Schia, 2018). The swift growth of e-government in several South Asian and Latin American states exceeds the regulatory capacity.

Gender-Disaggregated Analysis

Of 283 studies included in the review, 78 (27.6%) were gender-stratified and 22 studies focused on the gender-digital divide. The evidence shows that the positive impacts of ICTs on the SDGs go mostly to men and boys in developing

countries. The negative impacts, however, that include becoming a victim of digital fraud are a loss of income or job, and being unable to access digital public services are more likely to happen to women and girls. Rahman, Ara, and Chakma (2022) find that wealth, education and closeness to urban centres are the key predictors of mobile phone ownership among rural women in Bangladesh, patterns which reproduce rather than disrupt existing social hierarchies.

The Dual Impact Ict- Sdg Conceptual Framework

Framework Rationale and Design Principles: There is a need for a non-linear, multidirectional interpretation of ICT's role in sustainable development according to systematic review analysis. The ICTs can have both positive and negative effects around all key ICT categories and SDG domains. Notably, their net developmental outcome is a function not just of the technology itself but of the contextual conditions surrounding its deployment, governance, and use. Building on previous frameworks, we believe that the DI-ICT-SDG Framework takes an important step forward in four aspects. First, it is not only empirically based but also grounded on a corpus of 283 studies, meaning that the quality of studies was formally appraised. Second, it is operationalised through country-differentiated moderator indicators. Third, it integrates gender disaggregation as a structural analytical dimension. Fourth, it takes the form of contributions that reflect temporal dynamics. The framework consists of five design principles: (i) Dual-directional – keeping ICT pathways that are both positive (enabling) and negative (constraining) in simultaneous analytic view explicitly; (ii) Contextually mediated – identifying governance quality, digital literacy, institutional capacity and infrastructure readiness as moderating variables; (iii) SDG-integrated – mapping ICT effects across inter linkages among the goals; (iv) Gender-responsive – embedding gender disaggregation as a structural dimension; and (v) Policy-actionable – each element connects to a domain where policy intervention can shift the balance from constraining pathways to enabling pathways.

Framework Components

Component 1 – ICT Intervention Layer: This includes the use of all kinds of digital technologies, such as mobile money and FinTech; broadband and 5g; ehealth and mhealth; e-government; e-learning and digital education; agritech and digital agriculture; emerging technologies such as AI, IoT, blockchain; and the production and disposal cycle of ICT devices and infrastructure, including e-waste.

Component 2 – Dual Pathway Matrix: Differentiates the impacts of each ICT intervention category into an enabling pathway (positive SDG impact) and a constraining pathway (negative SDG impact). The quality of life in this context is further determined by factors such as mobile money and broadband internet access. The impact pathway of mobile money operates through financial inclusion, poverty alleviation and the utilisation of health services SDGs 1, 3, 8, while the inhibiting pathway operates through digital fraud, inclusion of digitall illiterate populations, regulatory arbitrage SDGs 10, 16. The processes through which ICT devices are manufactured, used, and discarded are producing unreasonable levels of e-waste, which could undermine progress towards SDG 3, 6 and 12.

Component 3 – Contextual Moderator Layer: Four moderating variables are identified which have been operationalised using internationally comparable indicators. The Quality of Governance is estimated through the World Governance Indicators (WGI) composite, particularly through Rule of Law, Regulatory Quality and Control of Corruption. UNESCO developed a Digital Skills Assessment Framework to measure digital literacy. The World Economic Forum Network Readiness Index Used for measuring Infrastructural readiness The governance dimensions of the Bertelsmann Transformation Index characterize institutional capacity.

Component 4 – Gender-Responsiveness Dimension: Gender acts as a cross-cutting structural dimension altering the Dual Pathway Matrix. The ICT intervention, be it aggregate impacts or gender-disaggregated impacts, is mediated by the quality of governance; whether or not gender-equitable ICT policies are enacted is shaped by quality of

governance; the digital literacy of women enables access to platforms by women, and quality of infrastructure readiness facilitates or shapes gender-differentiated patterns of connectivity.

Component 5 – Net SDG Outcome Assessment Protocol: A three-step protocol operationalizes net-impact assessment. Reviewers (direction): note whether the identified effects on the target SDG are enabling, constraining or both. Step two, where quantitative evidence is available, involves recording and comparison of the effect sizes across the governance environments. In step 3 an effort is made to classify net outcome as conditional positive (net positive under strong governance and high digital literacy), conditional negative (net negative under weak governance and low digital literacy), or context dependent (outcomes diverge across country categories).

Illustrative Case Applications

Rwanda (Strong Governance, High Infrastructure Readiness): The WGI composite suggests that Rwanda possesses moderate-to-strong governance, relative to Sub-Saharan Africa. It has been found that mobile money can help people to overcome poverty as well as to utilize resources in health centres. Rwanda's more active than average extended producer responsibility legislation mitigates e-waste constraining pathways. Rwanda's gender-responsive governance scores moderate country-wide gender-disaggregated outcomes and regional averages.

Bangladesh (Moderate Governance, Moderate Infrastructure): Bangladesh is an emerging market for mobile service financial (bKash, Nagad) that is growing rapidly and has strong enabling effects on SDG 1 and SDG 3, but Rahman et al. (2022) highlights a gender-digital divide whereby the enabling effects for women are considerably weaker. Due to weak EPR enforcement, e-waste has created an obvious constraining pathway (SDG 12, SDG 6). Bangladesh's net ICT-SDG outcome is classified as "conditionally positive with significant gender and environmental caveats."

DRC (Weak Governance, Low Infrastructure): In conditions of weak governance (WGI well below −0.5), low infrastructure readiness (Network Readiness Index: bottom decile), and minimal digital literacy (digital illiteracy), the framework predicts that constraining pathways (diluted through digital exclusion, e-waste contamination, cybersecurity vulnerability) dominate enabling pathways. The effective integration of ICT with the SDGs must first prioritize governance reform and infrastructure investment.

Policy Implications

Governance and Regulatory Priority: The identification of governance quality as the leading contextual moderator in the framework makes a case for a tiered strategy. In countries with strong governance capabilities (such as Rwanda, Botswana and Mauritius), the policy design priority should evolve to consider more optimised regulatory interventions. In moderate governance contexts such as Ghana, Kenya, Bangladesh, and Vietnam, selective sequencing is recommended, which means ICT is only deployed where regulatory preconditions exist while building up the capacity in other domains. In situations with weak governance (eg DRC, Yemen, Haiti), involvement of institutional development before large-scale deployment of ICT is vital.

Digital Literacy as Development Priority: Digital literacy is a necessary condition for ICTs to have a positive effect on development across the 283 studies considered. Essential actions should encompass the incorporation of digital literacy into national school curricula, with particular regard for gender; the construction of FinTech and mobile money platforms, to be developed with simple, multi-lingual user interfaces; investing in community digital literacy-based programmes, with gender-disaggregated outcome-monitoring, and the monitoring of digital literacy should be gender, age, income quintile, geography disaggregated using the UNESCO Digital Skills Assessment Framework.

Environmentally Sustainable ICT Policy: We must agree on an ICT Policy to support a green and environmentally sustainable future. As the evidence on the environmental impacts of ICT accumulates, a green ICT policy agenda must include: a requirement for environmental impact assessments for large-scale ICT infrastructure projects; a

requirement for formal e-waste collection and EPR schemes managed by electronics manufacturers; assistance with regional cooperation on e-waste; and the establishment of incentives for energy efficient ICT infrastructure with requirements linked to renewable energy sourcing targets.

Gender-Transformative ICT Policy: Developing countries need gender-transformative ICT policy, not gender-neutral ICT policy. The supporting evidence is for: Making gender-disaggregated digital access data collection a condition of international ICT development partnerships; embedding gender equity targets within USF programmes; mandating that ICT platform providers demonstrate gender-inclusive design standards as a condition of regulatory licensing; and funding gender-transformative digital skills programmes aiming to address social and normative barriers alongside deficits in technical skills.

Limitations and Future Research

Not without limitations, despite its advances over its predecessors. Language bias is partially addressed by inclusion of African Journals Online and use of French-language search terms, but the review is still mainly of English-language. The high-quality scholarship in French (particularly from francophone West Africa), Portuguese, and Arabic is under-represented in Campus. Secondly, despite having unique ICT-SDG dynamics associated with climate vulnerability and geographical isolation, the small island developing states (SIDS) are not well represented. Quality appraisal inter-rater reliability was not formally calculated, which is another limitation that merits addressing in future reviews. Fourth, case applications of the conceptual framework are illustrative, not formal empirical tests. The future research will have six priority directions. To begin with, longitudinal studies that track the changing impacts of ICT on the SDGs as technologies evolve and regulations develop. Next, a systematic consideration of how AI, IoT, and LLMs can be used in developing-country development programming. Third, contrasting governance settings within pairs of countries using the DI-ICT-SDG Framework. Fourth, conduct impact evaluations of gender-transformative ICT using pre-registered quasi-experimental designs. Research to expand geographic area of ICT-SDGs SIDS-specific activities Co-designed action research should be done with the affected communities, in particular, informal e-waste workers and digitally excluded women.

CONCLUSION

This systematic review and conceptual framework paper is the most comprehensive, methodologically rigorous and geographically representative synthesis, to date, of the dual impact of ICT on sustainable development in developing countries, based on 283 peer-reviewed studies published over the period 2015–2025, independently dual-screened ($\kappa = 0.83$) and quality-appraised using validated tools. The evidence suggests that ICT is not the unequivocal engine of development claimed by its most ardent supporters or the unmitigated cause of inequality and environmental degradation put forth by its most vigorous critics. Both simultaneous and the net balance between enabling and constraining effects is determined by governance quality, digital literacy, institutional capacity, and infrastructure readiness. The Dual-Impact ICT–SDG (DI-ICT-SDG) Conceptual Framework proposed in this paper is an advancement of the prior frameworks that does the following: it incorporates formal quality appraisal; it operationalises moderating variables with the help of internationally comparable indicators; it embeds gender disaggregation as a structural analytical dimension; it accommodates temporal dynamics; it demonstrates applicability through three illustrative case applications; and it generates country-differentiated rather than generic policy recommendations. The findings call for immediate policy actions on e-waste governance, digital divide mitigation, gender-transformative ICT programming, and energy-sustainable digital infrastructure. It is in these domains that the gap between current practice and what the evidence demands is most consequential for sustainable development in the Global South.

ACKNOWLEDGEMENT

The authors gratefully acknowledge the Department of Library and Information Science, Swami VivekanandSubharti University, Meerut, for providing the institutional support and academic environment that made this systematic review possible. Sincere thanks are extended to the university library for granting access to the bibliographic databases that formed the evidentiary backbone of this study

Funding: No external funding was received for this research. The authors received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors for the conduct of this study or the preparation of this manuscript.

Disclosure Statement: The authors declare that they have no known financial or non-financial competing interests that could have appeared to influence the work reported in this paper. The authors report there are no competing interests to declare.

Declaration of Generative AI Use: Generative AI tools were used solely to assist with language refinement, grammar improvement, and enhancement of the readability of the manuscript. The authors critically reviewed, revised, and verified all AI-assisted outputs and take full responsibility for the accuracy, integrity, and originality of the content. Generative AI was not used for data collection, data analysis, interpretation of findings, or the generation of scientific conclusions.

Authors' Profiles

Prof.Dr.SudhirTyagi is presently working as Professor & Head, Department of Library & Information Science, and Dean, Faculty of Arts & Social Sciences, Swami VivekanandSubharti University, Meerut. He holds MA (History), MA (Political Science), B.Ed., MLIS, M.Phil.and Ph.D. in Library and Information Science. He has more than 30 years of experience in the library and information science field. Dr.SudhirTyagi has published more than 79 research papers in national and international journals and conferences, and has authored a book on library management. He is a life member of several professional bodies, including the Indian Library Association (ILA), Library Professional Association (LPA), Uttar Pradesh Library Association (UPLA), and Indian Association of Teachers of Library and Information Science (IATLIS). He serves on the editorial boards of various professional journals. Under his supervision, eight Ph.D. scholars have been awarded doctoral degrees.

Contribution to the Study: Prof.Dr.SudhirTyagi provided overall research conceptualization, theoretical framework development, and academic supervision of the study. He guided the systematic review methodology, oversaw the application of PRISMA 2020 guidelines, and contributed to the development of the theoretical constructs including the Complementarity Principle and the Institutional Mediation Model. He also reviewed and finalized the manuscript for submission.

Dr.Sapna Sharma is presently working as Assistant Professor, Department of Library & Information Science, Faculty of Arts & Social Sciences, Swami VivekanandSubharti University, Meerut. She holds MA (History), MA (Hindi), MLIS, M.Phil., and Ph.D. in Library and Information Science. She has more than 24 years of experience in the library and information science field. She has published more than 33 research papers in national and international journals and conferences. She is a life member of the Indian Library Association (ILA), Library Professional Association (LPA), Uttar Pradesh Library Association (UPLA), and Indian Association of Teachers of Library and Information Science (IATLIS). Under her supervision, two Ph.D. scholars have been awarded doctoral degrees.

Contribution to the Study: Dr.Sapna Sharma led the study design and coordinated the overall research process. She was responsible for framing the research objectives, developing eligibility criteria using the PICO framework, and designing the search strategy. She conducted the primary literature search in Scopus, performed title/abstract screening, full-text eligibility assessment, and quality appraisal using the MMAT/CASP rubric. She also led the thematic synthesis, frequency analysis, and drafted the core sections of the manuscript.

Ms. Bhavana Joshi is a Junior Research Fellow (JRF) and Research Scholar in the Department of Library & Information Science, Faculty of Arts & Social Sciences, Swami VivekanandSubharti University, Meerut. She is currently pursuing her Ph.D. in Library and Information Science. She also serves as Assistant Librarian at Swami VivekanandSubharti University, Meerut, where she has gained hands-on professional experience in academic library services, digital information management, and user support. Her research interests include emerging technologies in libraries, artificial intelligence in information services, and user behaviour in digital environments.

Contribution to the Study: Ms. Bhavana Joshi assisted in data extraction using the standardized extraction form, contributed to citation snowballing and reference verification, and supported the compilation of bibliometric data. She also assisted in the preparation of tables, cross-checking of in-text citations against the reference list, and formatting of the manuscript in accordance with the journal's submission guidelines

Table 1: PRISMA 2020 Screening Summary

PRISMA Stage	Description	Count
Identification	Total records identified across 6 databases	691
Identification	Duplicates removed	127
Screening	Records screened (title & abstract); Inter-rater $\kappa = 0.83$	564
Screening	Records excluded (wrong geography, off-topic, pre-2015)	189
Eligibility	Full-text reviewed; excluded after review	197 / 92
Included	Final studies included in synthesis	283

Table 2: Impact Type Distribution among 283 Included Studies

Impact Category	Papers	% Total	Representative ICT Types
Both Positive & Negative	125	44.2%	Mobile money, e-waste, broadband, e-government
Positive Only	54	19.1%	mHealth, e-learning, agritech, FinTech
Negative Only	61	21.6%	E-waste, carbon emissions, digital divide
Mixed / Unclear	43	15.2%	Cross-country panels with contradictory results
TOTAL	283	100%	All seven ICT categories; all 17 SDGs

Table 3: Gender-Disaggregated Analysis of ICT's SDG Impacts

ICT Category	Documented Gender Gap	Policy Response	Relevant SDGs
Mobile Money / FinTech	Lower female ownership; social norms restrict use	Gender-equitable platform design; social tariffs	SDG 1, 5, 10
E-Learning	Lower enrolment among girls; device access gaps	Gender-inclusive curricula; device subsidies	SDG 4, 5
mHealth	Limited autonomy restricts women's platform access	Community health worker digital bridges	SDG 3, 5
Broadband	Urban-rural gender connectivity gap	Universal service fund gender quotas	SDG 9, 10
E-Government	Lower female digital literacy; mobility constraints	Simplified interfaces; multilingual design	SDG 5, 16
Agritech	Male-dominated extension systems exclude women	Gender-transformative extension models	SDG 2, 5

Table 4: SDG Coverage in the 283 Included Studies

SDG	Goal Name	Papers	% Total	Key ICT Linkage
SDG 9	Industry, Innovation & Infrastructure	98	34.6%	Digital infrastructure; broadband; 5G
SDG 7	Affordable & Clean Energy	53	18.7%	Energy-ICT nexus; renewable energy
SDG 1	No Poverty / Financial Inclusion	44	15.5%	Mobile money; FinTech; digital credit
SDG 3	Good Health & Well-Being	42	14.8%	mHealth; e-health; telemedicine
SDG 4	Quality Education	40	14.1%	E-learning; digital literacy; OER platforms
SDG 8	Decent Work & Economic Growth	38	13.4%	Digital economy; employment; productivity
SDG 12	Responsible Consumption	36	12.7%	E-waste; circular economy; green ICT
SDG 13	Climate Action	29	10.2%	Carbon emissions; energy efficiency
SDG 10	Reduced Inequalities	25	8.8%	Digital divide; gender gap; access inequality
SDG 5	Gender Equality	22	7.8%	Gender-digital divide; women's ICT access

ABSTRACT

In this article we replace the real numbers by ordering Banach space and define cone metric spaces (x ,d) we discuss some properties of convergence of sequences. We prove some fixed Point theorems for contractive mappings our results generalized in metric spaces and also the topology induced by topological vector space. The valued cone metric coincides with the topology induced by the metric obtained a nonlinear scalarization function, any topological vector space valued cone metric space is a metrizable, and also obtain some more results in topological vector space valued cone normed spaces.

Keywords: Normed space, Cone normed space, Cone metric space, TVS-cone metric space, Cone Banach spaces , Set-valued operators.

MSc Code: 46BXX

INTRODUCTION

A generalization of normed spaces, cone normed spaces play a very important role in fixed point theory, computer science and some other research areas as well as in function analysis. The concept of metric, and any concept related to metric play a very important role not only in pure mathematics but also in other branches of science involving mathematics specially in computer science, information science, and biological science The idea of using metric spaces in a systematic fashion goes back to Fréchet [1] and is justified by its great success. In 1980, Rzepecki [2] introduced a generalized metric d E on a set X in a way that dE : X ×X −→ S, where E is a Banach space and S is a

normal cone in E with partial order ≤. considered the notion of K-metric spaces by replacing real numbers with cone K in the metric function, d : X ×X −→ K. Lin's work, Long- Guang and Xian[4] announced the notion of a cone metric space by replacing real numbers with an ordering Banach spaces they also discussed some properties of convergence of sequences and proved the fixed point theorems of contractive mappings for cone metric spaces. The definition of normed space was first given by Banach [5], Hahn[6] , and Wiener [7]. The theory developed rapidly, as seen from the treatise by Banach [8] published Rzepecki introduced not only a generalized metric but also a generalized norm.
The result that the collection of open subsets of a cone metric space is a first countable Hausdorff topology suggests we ask if the topology of a cone metric space coincides with an appreciate metric defined on *X*. There are some proofs of metrizability of Banach space valued, and topological vector space valued cone metric spaces in the literature proved independently of each other [9,10], some of which are interesting. The equivalent metric in this paper is different from the others, much more simple and short [11] to prove that any TVS-cone metric space can be metrizable, i.e. the topology induced by the TVS- cone metric *p* coincides with the topology induced by an appreciate metric, that any TVS-cone metric space has a completion, and obtain some results in topological vector space valued cone normed spaces. A TVS-cone metric space is a generalization of a cone metric space in the sense that the ordered Banach space in the definition is replaced by an ordered TVS, Some properties of a cone metric space are also satisfied in TVS-cone metric space. we have to deal with neighborhoods while in the former with norm when we are to use the partial ordering. However, due to the change in the settings, the results are not always be analogous to those in Banach space valued cone metric spaces. we prove that not only cone metric spaces are metrizable, but also TVS-cone metric spaces are present a completion theorem.

A Cone Normed Spaces

Definition 2.1
Let X be a real vector space and E be a real Banach space. Suppose that the mapping $|||.||| : X \to E$ satisfies

- $|||x||| = 0 \quad x \Leftrightarrow$:
- $|||ax||| = |a| \, |||x|||$ for any scalar $\boldsymbol{\alpha}$ and any $x \in X$:
- $|||x+y||| \leq |||x||| + |||y|||$ for all $x, y \in X$.

Then $|||.|||$ is called a cone norm on X, and we call (x. $|||.|||$) a cone normed space. One can see that condition (c) means $|||x||| + |||y||| - |||x+y||| \in P$ for all $x \in X$. It is clear that $d(x, y) = |||x - y|||$ is a cone metric. Then *E* and *X* will denote a Banach space and cone Banach space, respectively, we use the symbol $||.||$ for the norm of *E* and $|||.|||$ for the cone norm of *X* . If we replace condition (a) by a weaker condition $|||.||| \in P$ for all $x \in X$, then we call such a $|||.|||$ a cone quasi-norm. Cone quasi-norms might play an important role in computer science as well as quasi-norms. Similar rapid development may be guessed for the definition of a cone normed space and the improvement of the theory of cone normed space and cone Banach space .

Example 2.2
Let $E = \mathbb{R}^2$ and P = [x ,y) : x ≥ 0 , y ≥ 0) .Then P is the positive cone of $\mathbb{R}^2$ under the partial ordering :
$(\boldsymbol{x_1}, \boldsymbol{y_1}) \leq (\boldsymbol{x_2}, \boldsymbol{y_2})$ iff $\boldsymbol{x_1} \leq \boldsymbol{x_2}$ and $\boldsymbol{y_1} \leq \boldsymbol{y_2}$, also it is clear that int P = (x,y) : x > 0,y>0)≠ ∅ . Let X = $\mathbb{R}^2$ and define $|||.||| : X \to E$ by $|||(\boldsymbol{x_1}, \boldsymbol{y_1})||| = (\boldsymbol{\alpha}|\boldsymbol{x_1}| , \boldsymbol{\beta}|\boldsymbol{y_1}|)$. Where $\boldsymbol{\alpha} > 0$, $\boldsymbol{\beta} > 0$. It is easy to see that $|||.|||$ is a cone norm and (x, $|||.|||$) becomes a cone normed space. Let (x, $|||.|||$) be a cone normed space, P be a normal cone with normal constant K. it is easy to show that there is a Banach space $\hat{\boldsymbol{x}}$ and an isometry T from X onto a subspace w of $\hat{\boldsymbol{x}}$ which is dense in $\hat{\boldsymbol{x}}$ by Theorem 1. The space $\hat{\boldsymbol{x}}$ is unique , except for isometries. This implies that any cone normed space can be completed. Let ((x, $|||.|||$) be cone normed space, and P a normal cone with normal constant K. Then we have $||\,|||y||| - |||x|||\,|| \leq k\,||\,|||y - x|||\,||$ and the mapping f : x →E defined f (x) = $|||x|||$ is continuous for any x ∈ X, for every $\boldsymbol{\varepsilon} > 0$ there is $\boldsymbol{\delta} \in E$ such that $\boldsymbol{\delta} = \frac{\boldsymbol{\varepsilon}}{2\boldsymbol{k^2}}\boldsymbol{z_0} \in E$ with $||\boldsymbol{z_0}|| = 1$. Thus, for every x in X with $|||x - \boldsymbol{x_0}||| < \,$, we have $||f(x) - f(\boldsymbol{x_0})|| = ||\,|||x||| - |||\boldsymbol{x_0}|||\,|| \leq K\,||\,|||x - \boldsymbol{x_0}|||\,||$

$$\leq K.K\,||\boldsymbol{\delta}|| = \boldsymbol{K^2}\,||\frac{\boldsymbol{\varepsilon}}{2\boldsymbol{k^2}}\boldsymbol{z_0}|| = \boldsymbol{K^2}\frac{\boldsymbol{\varepsilon}}{\boldsymbol{k^2}}||\boldsymbol{z_0}|| < \boldsymbol{\varepsilon}.$$

$\boldsymbol{A}$ cone Banach space X is a complete cone normed space. Completeness means that if $(\boldsymbol{x_n})$ is a Cauchy sequences in X then there exists x ∈ E such that $|||\ \boldsymbol{x_n}$ - x $|||$ →0 (n→ ∞). Let X be a cone normed space. We say that the series $\sum \boldsymbol{x_n}$ with $\boldsymbol{x_n}$ ∈ X ,converges to x ∈ X if $(\boldsymbol{S_n}) = (\boldsymbol{x_1}, \boldsymbol{x_1}+\boldsymbol{x_2}, \boldsymbol{x_1}+\boldsymbol{x_2}+\boldsymbol{x_3},\ldots)$converges to x , i.e., $||\ \boldsymbol{S_n}$ - x $||$ → 0 as n → ∞. Then we write $\sum_{n=1}^{\infty} \boldsymbol{x_n}$ = x ,A series $\sum \boldsymbol{x_n}$ is called absolutely convergent if and only if $\sum |||\ \boldsymbol{x_n}\ |||$ is convergent in E.
As in a classical normed space. Any Cauchy sequence with a convergent subsequence is convergent and the sequence of general terms of a convergent series is a null sequence in a normed space. i.e., if a series $\sum \boldsymbol{x_n}$ is convergent , then $\boldsymbol{\lim_{x_n} = 0}$.

Let E be a Banach space and P a normal cone with a normal constant k .Take any series $\sum \boldsymbol{x_n}$ and $\sum \boldsymbol{y_n}$ in E. If $0 \leq \boldsymbol{x_n} \leq \boldsymbol{y_n}$ for all n and the series $\sum \boldsymbol{y_n}$ is convergent. Then the series $\sum \boldsymbol{x_n}$ is convergent.

Theorem 2.3
A cone normed space X is complete if and only if every absolutely convergent series is convergent.
Proof :
Let X be complete and $\sum \boldsymbol{x_n}$ be absolutely convergent. Then for n > m.

$$|||\ \mathbf{S_n} - \mathbf{S_m}\ ||| = |||\ \mathbf{x_{m+1}} + \ldots + \boldsymbol{x_n}\ ||| \leq |||\ \mathbf{x_{m+1}}||| + \ldots + |||\ \boldsymbol{x_n}|||\rightarrow 0(m\rightarrow \infty).$$

Hence $(\mathbf{S_n})$ is Cauchy and so is convergent. There fore $\sum \boldsymbol{x_n}$ converges. Suppose that every absolutely convergent series is convergent. Let $(\boldsymbol{x_n})$ be a Cauchy sequence in x .Take any c ∈ int P. then we can find $\boldsymbol{n_1} < \boldsymbol{n_2} <$ satisfying

$$|||\ \boldsymbol{x_{n_{k+1}}} - \boldsymbol{x_{n_k}}\ ||| << \frac{\boldsymbol{c}}{\boldsymbol{2^k}}\ (\text{k} = 1,2,\ldots)$$

So that $\sum \frac{\boldsymbol{c}}{\boldsymbol{2^k}}$ is a convergent series. $\sum |||\ \boldsymbol{x_{n_{k+1}}} - \boldsymbol{x_{n_k}}|||$ is convergent .From the assumption it follows that $\sum (\boldsymbol{x_{n_{k+1}}} - \boldsymbol{x_{n_k}})$ converges. We see that $(\boldsymbol{x_{n_k}})$ converges. Hence the Cauchy sequence $(\boldsymbol{x_n})$ has a convergent subsequence $(\boldsymbol{x_{n_k}})$ and so the whole sequence $(\boldsymbol{x_n})$ converges. Consequently X is complete.

Theorem 2.4
Let (X, $|||.|||$) be a cone normed space and $(\boldsymbol{x_n})$ a sequence in X . If $(\boldsymbol{x_n})$ converges to 0, then $(\frac{\boldsymbol{x_1+x_2+\cdots+x_n}}{\boldsymbol{n}})$converges to 0.

Proof:
Suppose that $(\boldsymbol{x_n})$ converges to 0. Then given any c ∈ intP, there is $\boldsymbol{N_1}$ such that for all n $> \boldsymbol{N_1}$, $|||\ \boldsymbol{x_n}\ ||| << \frac{\boldsymbol{c}}{\boldsymbol{2}}$, for this $\boldsymbol{N_1}$; $\frac{\boldsymbol{1}}{\boldsymbol{n}} |||\ \boldsymbol{x_1}+ \ldots + \boldsymbol{x_{N_1}}|||$ converges to 0. Hence there is $\boldsymbol{N_2}$ such that for all n > $\boldsymbol{N_2}$, $\frac{\boldsymbol{1}}{\boldsymbol{n}} |||\ \boldsymbol{x_1}+ \ldots + \boldsymbol{x_{N_1}}||| << \frac{\boldsymbol{c}}{\boldsymbol{2}}$, Now write N = max $(\boldsymbol{N_1}, \boldsymbol{N_2})$. Then for n > N.

$$\left\|\frac{x_1+x_2+\cdots+x_n}{n}-0\right\| \leq \frac{\|x_1+x_2+\cdots+x_{N_1}\|}{n}+\frac{\|x_{N_1+1}+\cdots+x_n\|}{n}$$
$$\leq \frac{1}{n}(\|x_1+\cdots+x_{N_1}\|)+\frac{1}{n}(\|x_{N_1+1}\|+\cdots+\|x_n\|)$$
$$\ll \frac{c}{2}+\frac{1}{n}(n-N_1-1+1)\frac{c}{2}=\frac{c}{2}+\frac{1}{n}(n-N_1)\frac{c}{2}\ll\frac{c}{2}+\frac{c}{2}=c.$$

This completes the proof of the theorem.

Theorem 2.5
Let (X, $|||.|||$) be a cone normed space , $(\boldsymbol{x_n})$ $\boldsymbol{\alpha}$ sequence in X, a sequence $(\mathbf{p_n})$ of non-negative number which are not all 0, and

$$\mathbf{P_n} = \mathbf{P_1}+\mathbf{P_2}+ \ldots+\mathbf{P_n}\ \ (\text{n}=1,2,\ldots): \mathbf{P_1}>0.$$

If $(\boldsymbol{x_n})$ converges to x and $(\frac{\mathbf{p_n}}{\mathbf{p_n}})$ converges to 0. Then the sequence $(\boldsymbol{y_n})$ defined by $\boldsymbol{y_n} = \frac{\boldsymbol{P_n x_1+P_{n-1}x_2+\cdots P_1 x_n}}{\boldsymbol{P_n}}$ also converge to x.

Proof:

Suppose that $(\boldsymbol{x_n})$ converges to x and $(\frac{\mathbf{p_n}}{\mathbf{p_n}})$ also converges to 0. Take any c ∈ intP. Then there is $\mathbf{N_0}$ such that ||| $\mathbf{x_n}$ -x ||| $<< \frac{c}{2}$ for all n > $\mathbf{N_0}$,From $\frac{\mathbf{P_n - k + 1}}{\mathbf{P_n - k + 1}} \to 0$ (k=1,2,… $\mathbf{N_0}$) , for every $\frac{c}{2N_0} \in$ intP there is $\mathbf{N_k}$ such that $\frac{\mathbf{P_n - k + 1}}{\mathbf{P_n - k + 1}}$ ||| $\mathbf{x_k}$ -x ||| $<< \frac{c}{2N_0}$ (k=1,2,… $\mathbf{N_0}$) for all n > $\mathbf{N_k}$. write N =max ($\mathbf{N_0}$, $\mathbf{N_1}$,…$\boldsymbol{N_{N_0}}$) .Then , for n > N.

$$\leq \frac{p_n}{P_n}\|x_1 - x\| + \cdots + \frac{p_{n-N_0+1}}{P_n}\|x_{N_0} - x\| + \frac{p_{n-N_0}}{P_n}\|x_{N_0+1} - x\| + \cdots + \frac{p_1}{P_n}\|x_n - x\|$$

$$\leq \frac{p_n}{P_n}\|x_1 - x\| + \cdots + \frac{p_{n-N_0+1}}{P_{n-N_0+1}}\|x_{N_0} - x\| + \frac{p_{n-N_0}}{P_n}\|x_{N_0+1}\| + \cdots + \frac{p_1}{P_n}\|x_n - x\|$$

$$\ll \underbrace{\frac{c}{2N_0} + \frac{c}{2N_0} + \cdots + \frac{c}{2N_0}}_{N_0 \text{ times}} + \frac{c}{2}\left(\frac{p_{n-N_0} + \cdots + p_1}{P_n}\right) \leq \frac{c}{2} + \frac{c}{2} = c.$$

This proves that $y_n = \frac{p_n x_1 + p_{n-1} x_2 + \cdots + p_1 x_n}{P_n} \to x$ as $n \to \infty$.

Definition 2.6

Let X be a cone normed space . A subset of X is called N-sequentially compact if whenever $(\boldsymbol{x_n})$ is a sequence of points in A, there is a subsequence $(\boldsymbol{X_{k_n}})$ of $(\boldsymbol{X_n})$ with N –lim $\boldsymbol{X_{k_n}}$ = lim $\frac{\boldsymbol{P_n x_1 + P_{n-1} x_2 + \cdots P_1 x_n}}{\boldsymbol{P_n}}$ = z ∈ A.

Theorem 2.7

Let (X,|||.|||) be a cone normed space , $(\boldsymbol{X_n})$ be a sequence in X, a sequence $(\boldsymbol{P_n})$ of non- negative numbers which are not all 0, and

$$(\boldsymbol{P_n}) = \boldsymbol{P_1} + \boldsymbol{P_2} + \ldots + \boldsymbol{P_n} \text{ (n=1,2,…); } \boldsymbol{P_1} > 0$$

If $(\boldsymbol{x_n})$ converges to x and $\boldsymbol{P_n} \to \infty$, $(\boldsymbol{y_n}) = \frac{\boldsymbol{P_n x_1 + P_{n-1} x_2 + \cdots P_1 x_n}}{\boldsymbol{P_n}}$ also converge to x.

Proof:

Suppose that (x_n) converges to x and $P_n \to \infty$ as $n \to \infty$. Take any $c \in \text{int}P$. Then there is N_0 such that for all $n > N_0$, $\|x_n - x\| \ll \frac{c}{2}$. From $P_n \to \infty$, $\frac{p_i}{P_n} \to 0$ $(i = 1, 2, \ldots, N_0)$. For every $\frac{c}{2N_0} \in \text{int}P$ there is N_k such that for all $n > N_k$, $\frac{p_k}{P_n}\|x_k - x\| \ll \frac{c}{2N_0}$ $(k = 1, 2, \ldots, N_0)$. Then, for $n > \max\{N_0, N_1, \ldots, N_{N_0}\}$,

$$\|y_n - x\| = \left\|\frac{p_1 x_1 + p_2 x_2 + \cdots + p_n x_n}{P_n}\right\|$$

$$= \left\|\frac{p_1(x_1 - x) + p_2(x_2 - x) + \cdots + p_n(x_n - x)}{P_n}\right\|$$

$$\leq \frac{p_1}{P_n}\|x_1 - x\| + \frac{p_2}{P_n}\|x_2 - x\| + \cdots + \frac{p_n}{P_n}\|x_n - x\|$$

$$= \frac{p_1}{P_n}\|x_1 - x\| + \cdots + \frac{p_{N_0}}{P_n}\|x_{N_0} - x\| + \frac{p_{N_0+1}}{P_n}\|x_{N_0+1} - x\| + \cdots + \frac{p_n}{P_n}\|x_n - x\|$$

$$\ll \underbrace{\frac{c}{2N_0} + \cdots + \frac{c}{2N_0}}_{N_0 \text{ times}} + \frac{c}{2}\left(\frac{p_{N_0+1} + \cdots + p_n}{P_n}\right) \leq \frac{c}{2} + \frac{c}{2} = c.$$

This proves that $y_n = \frac{p_1 x_1 + p_2 x_2 + \cdots + p_n x_n}{P_n} \to x$ as $n \to \infty$.

A Cone Metric Space

Definition 3.1

Let *E* be a real Banach space. A subset *P* of *E* is called a cone if and only if:

(a) P is closed, nonempty, and $P \neq \{0\}$,

(b) a , b ∈ R , a, b ≥ 0 , x , y ∈ P ax + by ∈ P. ⇨

(c) x ∈ P and –x ∈ P x = 0. ⇨

Given a cone P⊂E, we can define a partial ordering ≤ with respect to P by $x \leq y$ if and only if y-x∈P . We write x < y to indicate that $x \leq y$ but $x \neq y$, while x << y will stand for y-x∈ int P, int P denotes the interior of P. In cones are required to be restricted to a special case, namely to normal cones. The cone P is called normal if there is a constant number K > 0 such that for all x, y ∈ E

$$0 \leq x \leq y \text{ implies } ||x|| \leq K||y||.$$

The least positive number satisfying the above inequality is called the normal constant of P.

We always suppose that E is a Banach space, P is a cone in E with int $P \neq \emptyset$ and ≤ is partial ordering with respect to P.

Definition 3.2

Let X be a nonempty set. Supose the mapping d: X x X → E satisfies

(a) $0 \leq d(x, y)$ for all x , y∈X and d (x,y)=0 if and only if x = y;

(b) d(x, y) =d (y, x) for all x , y ∈X:

(c) $d(x, y) \leq d(x, z)+d(z, y)$ for all x, y, z∈X.

Then d is called a cone metric on X , and (X , d) is called a cone metric space.

If we replace condition (a) by a weaker condition $d(x,y) \geq 0$ for all x , y ∈ X, then we call such a d a cone quasi-(pseudo)-metric. From we obtain by induction the following generalized triangle inequality

$d (x_1 , x_n) \leq d (x_1 , x_2) + d (x_2 , x_3) + \ldots + d (x_{n-1} , x_n)$.

A subspace of (Y ,d) of (X , d) is obtained if we take a subset Y ⊂ x and restrict d to Y x Y ; thus the cone metric on Y is restriction

d = d/Y x Y

d is called the cone metric induced on Y by d.

Example 3.3

Let $E = R^2$, $P = \{(x, y) \in E : x, y \geq 0\}$, X = R and $d : X \times X \longrightarrow E$ such that $d(x, y) = (|x - y|, \alpha|x - y|)$, where $\alpha \geq 0$ is a constant. Then (X, d) is a cone metric space.

Definition 3.4

Let (X,d) be a cone metric space , x ∈ X and (x_n) be a sequence in x .

- If for every c ∈ int P there is a positive integer N such that for all n > N ,d $(x_n , x) \ll c$, then (x_n) is said to be convergent and (x_n) converges to x and x is called the limit of (x_n).We denote this by $lim_n\, x_n = x$ or $x_n \to x$ (n→ ∞) .
- If for every c ∈ int P there is a positive integer N such that for all n, m > N ,d $(x_n , x_m) \ll c$, then (x_n) is called a Cauchy sequence in X.
- If every Cauchy sequence is convergent in X , then X is called a complete cone metric space.

Lemma 3.5

Let E be a real Banach space and P be a cone in E and suppose that x∈ E. Given any c∈int P there is a positive integer N such that $\frac{1}{n}x \ll c$, for all n > N.

Proof: For each $\varepsilon > 0$ there is an N such that $||\frac{1}{n}x|| < \varepsilon$ for all n > N since $(\frac{1}{n}x)$ converges to 0 in E. On the other hand, c ∈ int P, there is a $\delta > 0$ such that $\frac{c}{2} + B_\delta(0) \subset P$. For this , there is an N such that for all $n > N'$, $||\frac{1}{n}x|| = ||-\frac{1}{n}x|| <$

$\boldsymbol{\delta}$.Therefore for all n > $\boldsymbol{N}'$, $-\frac{1}{n}x \in \boldsymbol{B_\delta}(0)$.Hence $\frac{c}{2} - \frac{1}{n}x \in$ P and $\frac{c}{2} \in$ int P which imply that $(\frac{c}{2} - \frac{1}{n}x + \frac{c}{2}) = c - \frac{1}{n} \in$ int P. This completes the proof of the lemma.

Definition 3.6

Let d : X → E and d : Y → E be cone metrics.

A mapping T of X into Y is said to be cone isometric or a cone is ometry if T Preserves distance , that is , if for all x, y ∈ X. d (Tx, Ty) = d (x,y) here Tx and Ty are the images of x and y, respectively. The space X is said to be cone isometric with the space $\overline{\boldsymbol{X}}$ if there exists a bijective isometry of X onto $\overline{\boldsymbol{X}}$.

Theorem 3.7

Let (X,d) be a cone metric space , P be a normal cone with normal constant K. For (X , d) there exists a complete cone metric space (X , d) which has s subspace W that is isometric with X and is dense in X. This space $\widehat{\boldsymbol{X}}$ is unique except for isometrics, that is , if $\overline{\boldsymbol{X}}$ is any complete cone metric space having a dense subspace $\overline{\boldsymbol{W}}$ isometric with X, then $\overline{\boldsymbol{X}}$ and $\widehat{\boldsymbol{X}}$ are isometric.

Proof:

(a) $\widehat{\boldsymbol{X}} = (\widehat{\boldsymbol{X}} , \widehat{\boldsymbol{d}})$

(b) ***an*** isometry T of X onto W, where $\overline{\boldsymbol{W}} = \widehat{\boldsymbol{X}}$.

(c) ***completeness*** of $\widehat{\boldsymbol{X}}$.

(d) ***uniqueness*** of $\widehat{\boldsymbol{X}}$, except for isometries.

Construction of $\widehat{\boldsymbol{X}}$ ($\widehat{\boldsymbol{X}}$, $\widehat{\boldsymbol{d}}$).Let $(\boldsymbol{x}_n')$ be Cauchy sequences in X. Define$(\boldsymbol{X_n})$to be equivalent to $(\boldsymbol{x}_n')$,written $(\boldsymbol{X_n}) \sim (\boldsymbol{x}_n')$, if $\lim_{n\to\infty} \boldsymbol{d}(\boldsymbol{X_n} , \boldsymbol{x}_n')=0$.

Let $\widehat{\boldsymbol{X}}$ be the set all equivalence classes $\widehat{\boldsymbol{X}}$, $\widehat{\boldsymbol{Y}}$,…. of Cauchy sequences thus obtained.

We write $(\boldsymbol{X_n}) \in \widehat{\boldsymbol{X}}$ to mean that $(\boldsymbol{X_n})$ is a member of $\widehat{\boldsymbol{X}}$, in other words , $(\boldsymbol{X_n})$ is a representative of the class $\widehat{\boldsymbol{X}}$ .we define

$\hat{\mathbf{d}}$ ($\hat{\mathbf{x}}$, $\hat{\mathbf{y}}$) = $\lim_{n\to\infty} \boldsymbol{d}$ ($\boldsymbol{X_n}$, $\mathbf{y_n}$)

where $(x_n) \in \hat{x}$ and $(y_n) \in \hat{y}$. We show that this limit exists. We know that for all $\varepsilon > 0$ there is $c \in$ int P such that $K\|c\| < \varepsilon$. Since (x_n) and (y_n) are Cauchy sequences, for $c \in$ int P there are positive integers N_1 and N_2 such that

$d(x_n , x_m) << \frac{c}{2}$ (n , m ≥ N_1) , $d(y_n , y_m) << \frac{c}{2}$ (n , m ≥ N_2)

If we take $N = \max\{N_1, N_2\}$, we obtain for all $n, m \geq N$

$$||d(X_n , y_n) - d(x_n' , y_n')|| \leq k [||d(x_n' , x_n')|| + d(y_n , y_n')||] \to 0$$

as n → ∞ , which implies the assertion

$$\lim_{n\to\infty} \boldsymbol{d}\ (\boldsymbol{x_n} , \mathbf{y_n}) = \lim_{n\to\infty} \boldsymbol{d}\ (\boldsymbol{x}_n' , \boldsymbol{y}_n')$$

It is easy to show the $\hat{\mathbf{d}}$ in (2) is a cone metric on $\hat{\boldsymbol{x}}$.

Construction of an isometry T: x → W ⊂ $\hat{\mathbf{x}}$ with each b ∈ X we associate the class $\widehat{\boldsymbol{b}} \in \widehat{\boldsymbol{X}}$ which contains the constant sequence (b,b,…) . This define a mapping T: x → W onto subspace W = T (x) ⊂ $\widehat{\boldsymbol{X}}$ .The mapping T is given be b → $\hat{\mathbf{b}}$ =Tb , where (b,b,…) ∈ $\hat{\mathbf{b}}$. we see that T is an isometry since (2) implies

$\widehat{\boldsymbol{d}}$ ($\widehat{\boldsymbol{b}}$, $\hat{\boldsymbol{c}}$) = $\lim_{n\to\infty} \boldsymbol{d}$ (b,c) = d (b,c)

in which $\hat{\boldsymbol{c}}$ is the class of $(\boldsymbol{y_n})$ where $\boldsymbol{y_n}$ =c for all n. Also T is bijective, hence W and x are cone isometric, Now we show that W is dense in $\widehat{\boldsymbol{X}}$. we take any $\hat{\mathbf{x}} \in \hat{\mathbf{x}}$. Let $(\boldsymbol{x_n}) \in \hat{\mathbf{x}}$ .For every c ∈ int P there is an N such that

$$d(\boldsymbol{x_n} , \boldsymbol{x_N}) << \frac{c}{2} \quad (n > N).$$

Let ($\boldsymbol{x_N}$, $\boldsymbol{x_N}$,…) ∈ $\hat{\boldsymbol{x}}_n$ .Then $\hat{\boldsymbol{x}}_n \in$ W.by (2)

$\hat{\mathbf{d}}$ ($\hat{\mathbf{x}}$, $\hat{\boldsymbol{x}}_n$) = $\lim_{n\to\infty} \boldsymbol{d}$ ($\boldsymbol{x_n}$, $\mathbf{x_N}$)≤ $\frac{c}{2}$ << c.

This shows that every c-neighborhood of arbitrary $\hat{\mathbf{x}} \in \hat{\mathbf{X}}$ contains an element of w. Hence w is dense in $\hat{\mathbf{x}}$.

(c) Completeness of $\hat{\mathbf{x}}$ .Let $(\hat{\boldsymbol{x}}_n)$ be any Cauchy sequence in $\hat{\mathbf{x}}$. Since W is dense in $\hat{\mathbf{x}}$, for every $\hat{\boldsymbol{x}}_n$ and constant $\boldsymbol{c_0} \in$ int P there is a $\hat{\boldsymbol{z}}_n \in$ W such that

$$\hat{\mathbf{d}}\ (\hat{\boldsymbol{x}}_n , \hat{\boldsymbol{z}}_n) << \frac{c_0}{n}$$

Hence by the triangle inequality.

$\hat{\mathbf{d}}(\hat{z}_m, \hat{z}_n) \leq \hat{\mathbf{d}}(\hat{z}_m, \hat{x}_m) + \hat{\mathbf{d}}(\hat{x}_m, \hat{x}_n) + \hat{\mathbf{d}}(\hat{x}_n, \hat{z}_n) << \frac{c_0}{m} + \hat{\mathbf{d}}(\hat{x}_m, \hat{x}_n) + \frac{c_0}{n}$

It follows from Lemma 1 that the right side of the above inequality is much less than any given c ∈ int P for sufficiently large m and n because $(\hat{x}_n)$ is Cauchy. Hence $(\hat{z}_m)$ is Cauchy. Since T : X → W is isometric and $\hat{z}_m \in W$, the sequence (z_m) defined by $z_m = T^{-1}\hat{z}_m$ for each m is Cauchy in X. Let $\hat{x}$ be the class to which (z_m) belongs .By (4).

$\hat{\mathbf{d}}(\hat{x}_n, \hat{x}) \leq \hat{\mathbf{d}}(\hat{x}_n, \hat{z}_n) + \hat{\mathbf{d}}(\hat{z}_n, \hat{x}) << \frac{c_0}{n} + \hat{\mathbf{d}}(\hat{z}_n, \hat{x})$

Since $(z_m) \in \hat{x}$ and $\hat{z}_n \in W$, we get $(z_n, z_n, z_n, \ldots) \in \hat{z}_n$.Therefore inequality (5) becomes

$\hat{\mathbf{d}}(\hat{x}_n, \hat{x}) << \frac{c_0}{n} + \lim_{n\to\infty} d(z_n, z_N) << c$

For sufficiently large n. This gives the completeness of $\hat{x}$.

(d) Uniqueness of $\hat{x}$ except for cone isometries . If $(\bar{x}, \bar{d})$ is another complete cone metric space with a subspace $\bar{w}$ dense in X and cone isometric with X, then for any $\bar{x}, \bar{y} \in \bar{x}$ we have sequences $(\hat{x}_n)$ and $(\hat{y}_n)$ in $\bar{w}$ such that $\hat{x}_n \to \bar{x}$ and $\hat{y}_n$ -$\bar{y}$. since

$||\bar{d}(\bar{x}, \bar{y}) - \bar{d}(\hat{x}_n, \hat{y}_n)|| \leq K[\,||\bar{d}(\bar{x}, \bar{x}_n)|| + ||\bar{d}(\bar{y}_n, \bar{y})||\,] \to 0$

Then

$\bar{d}(\bar{x}, \bar{y}) = \lim_{n\to\infty} \bar{d}(\bar{x}_n, \bar{y}_n)$.

Since $\bar{W}$is cone isometric with $W \subset \hat{X}$ and $\bar{W} = \hat{X}$, the distance on $\bar{X}$ and $\bar{X}$ must be the same . Hence $\hat{X}$ and $\bar{X}$ are cone isometric.

TVS – CONE METRIC SPACE

Definition 4.1

Let x be a nonempty set and let a vector-valued function p : X x X → Y, be a function satisfying the following :

(a) θ 4K p(x, y) for all x, y ∈ X and p(x, y) = θ if and if only x = y;

(b) p(x, y) = p(y, x) for all x, y ∈ X ;

(c) p(x, z) 4K p(x, y) + p(y, z) for all x, y, z ∈ X .

Then the function *p* is called a topological vector space valued cone metric (TVS-cone metric for short) on *X* , and *(X, p)* is said to be a topological vector space valued cone metric space.

The well-known nonlinear scalarization function ξ_e : Y → R is defined as follows:

$\xi_e(y) = inf\{r \in R : y \in re - K\}$, *for all* $y \in Y$.

Lemma 4.2

(i) $\xi_e(y) \leq r$ $y \in re - k$;

(ii) $\xi_e(y) > r$ $y \in re - k$;

(iii) $\xi_e(y) \geq r$ $y \in re - intk$;

(iv) $\xi_e(y) < r$ $y \in re - intk$;

(v) $\xi_e(.)$is positively homogeneous and continuous on Y;

(vi) if $y_1 \in y_2 + k$, then $\xi_e(y_2) \leq \xi_e(y_1)$;

(vii) $\xi_e(y_1 + y_2) \leq \xi_e(y_1) + \xi_e(y_2)$ for all $y_1, y_2 \in Y$.

In the setting, we have to deal with neighborhoods while in the former we deal with norm when we are to use the partial ordering. However, due to the change in the settings, the proofs are not always be analogous to those in Banach space valued cone metric spaces. In this section, we prove that not only cone metric spaces are metrizable, but also TVS-cone metric spaces are, and present a completion theorem. First we note that for any fixed point in int *K* , there exists a positive integer *m* such that $\frac{1}{n}c \in$ int *K* for $n \geq m$. It is easy to see that for any open neighborhood *U* of zero there is a $c_0 \in$ int *K* such that $c_0 \in U$. We also note that for each $c \in$ int *K* , there exists an open neighborhood *U* of zero such that $c - x \in$ int *K* whenever $x \in U$.

Lemma 4.3

Let K be a cone in Y . Then the following conditions are satisfied:

(i) λint K ⊆ int K for any positive real number λ;

(ii) int K + int K ⊆ int K;

(iii) K + int K ⊆ int K;

(iv) if a ≪ b and b ≪ c, then a ≪ c for any a, b, c ∈ Y;

(v) if a 4_K b and b ≪ c, then a ≪ c for any a, b, c ∈ Y .

Proof:

The proofs of assertions are easily obtained by using main properties of a cone, so are omitted.

To obtain one of our main results that any TVS-cone metric space is a topological space, we prove the following lemma.

Lemma 4.4

Let (X, p) be a TVS-cone metric space. Then, for each c_1 ∈ int K and c_2 ∈ int K, there exists c ∈ int K such that c ≪ c_1 and c ≪ c_2.

Proof:

Let c_1 ∈ int K , and c_2 int K . Since c_1 ∈ int K , there exists an open, convex, and symmetric neighborhood U of zero such that $U \subset -c_1$ int K . Similarly there exists an open, convex, and symmetric neighborhood V of zero such that $V \subset -c_2$ + int K . Write $W = U \cap V$ .Thus W is an open, convex, and symmetric neighborhood of zero. Therefore W ⊂$-c_1$ int K *and* W ⊂$-c_2$ + int k . Since for this fixed c_1 the sequence ($\frac{c_1}{n}$) converges to 0 . there exists positive integer m such that $\frac{c_1}{m}$ ∈ W .c = $\frac{c_1}{m}$,say since w is a symmetric set, then –c ∈ W .Therefore –c + c_1 ∈ int k and –c + c_2 ∈ int K. Consequently, we find c ≪ c_1 and c ≪ c_2 .

Theorem 4.5

Every TVS-cone metric space (X, p) is a topological space.

Proof:

For c ∈ int K , let B(x, c) = {y ∈ X : d(x, y) ≪ c} and β = {B(x, c) : x ∈ X, c ∈ int K }. Then, τ_c = {U ⊂ X : ∀x ∈ U, ∃B ∈ β, x ∈ B ⊂ U } ∪ {∅}is a topology for X .

(τ_1) ∅, X ∈ τ_c .

(τ_2) Let U, V ∈ τ_c and let x ∈ U ∩ V then x ∈ U and x ∈ V , find c_1 ∈ int K , c_2 ∈ int K such that x ∈ B(x, c_1) ⊂ U and x ∈ B(x, c_2) ⊂ V . By Lemma 3.2, find c ∈ int K such that c ≪ c_1 and c ≪ c_2. Then, x ∈ B(x, c) ⊂ B(x, c_1) ∩ B(x, c_2) ⊂ U ∩ V . Hence V ∩ V ∈ τ_c .

(τ_3) Let Uα ∈ τ_c for each α ∈ Δ and let x ∈ $\cup_{\alpha\in\Delta}$ Uα then ∃α_0 ∈ Δ such that x ∈ Uα0 . Hence find c ∈ int K such that x ∈ B(x, c) ⊂ Uα0 ⊂ $\cup_{\alpha\in\Delta}$ Uα . That is $U_{\alpha\in\Delta}$ Uα ∈ τ_c

Now we give a theorem which enables us to obtain that the topology induced by a certain metric which is coarser than the topology induced by the cone metric p.

Lemma4.6

Let (X, p) be a TVS-cone metric space, d_p:=ξ_e ∘p, and x ∈X. Then (X, d_p) is a metric space, and B_dp (x, r) = B_p(x, re).

Proof:

It is known that d_p is a metric by Theorem 4.5 in [14]. Now assume that y ∈ B_dp (x, r), then d_p(x, y) = ξ_e(p(x, y)) < r . By the (iv) of Lemma 4.2, if we have p(x, y) ∈ re − int K , then p(x, y) ≪ re. Finally we have y ∈ B_p(x, re). Similarly y ∈ B_p(x, re z), then p(x, y) ∈re − int K . By the (iv) of Lemma 4.2, we have d_p(x, y) = ξ_e(p(x, y)) < r . Finally we have y ∈B_dp (x, r).

Lemma4.7

The class {B_P (x,$\frac{e}{n}$) : n s a positive integer} is a local base at the point x for each x in the TVS-cone metric space (x,p)

Proof

It is easy to see that … $\frac{1}{n+2}e \ll \frac{1}{n+2}e \ll \frac{1}{n}e \ll e$ for each positive n, We also see that $\frac{1}{n}e$ v→0 as n tends to ∞ where the convergence is in the order obtained by the cone K. otherwise we can construct a sequence of positive integers (n_k) such that c - $\frac{e}{n_k} \in$ int K for each positive integer k and for a fixed element c in the int K. Hence c - c - $\frac{e}{n_k} \in (\text{int } K)^c$ for each positive integer k where $(\text{int } K)^c$ denotes the complement of int K. This implies that c ∈ $(\text{int } K)^c$. This is a contradiction. This completes the proof of the lemma.

CONCLUSION

We would like to emphasize that the present work contains not only the proofs of metrizability of a TVS- cone metric space and normability of a TVS- cone normed space, but also some useful theorems involving Cauchy sequences. we suggest to investigate further results related to convergence of a sequence, and continuity of a function both in a TVS-cone metric space and a TVS- cone normed space. We also suggest to investigate the case for fuzzy cone metric spaces and fuzzy cone normed spaces.

ABSTRACT

Transcranial Direct Current Stimulation (tDCS), primarily aimed at the dorsolateral prefrontal cortex (DLPFC), is an extensively researched, non-invasive treatment for Major Depressive Disorder (MDD). Notwithstanding its therapeutic potential, clinical outcomes are moderate and highly variable, a challenge primarily ascribed to significant inter-individual differences in cranial architecture. The anatomical variability results in a standardized tDCS protocol producing significantly varied Electric Field (E-field) strength and distribution among patients, frequently failing to effectively stimulate the desired neuronal target. This paper analyzes the essential function of computational modeling, particularly using the Finite Element Method (FEM) and the SimNIBS software package, as a crucial approach to addressing this variability. We elucidate how SimNIBS employs unique structural MRI data to create tailored head models, facilitating the precise measurement of the patient-specific electric field. Recent literature emphasizes the clinical significance of this approach, revealing substantial correlations between simulated E-field magnitudes in critical depression-related circuits (e.g., DLPFC and ACC) and the observed antidepressant response, thus laying the groundwork for the optimization of personalized tDCS treatment. We summarize the present importance of this modeling, address key limitations—including uncertainties in tissue conductivity and the static characteristics of FEM—and outline future

directions, such as the creation of hybrid brain network models and the necessity for efficient methodologies to incorporate E-field-optimized protocols into standard clinical practice. Ultimately, computational modeling is crucial for converting tDCS into a precise neuro modulation therapy for MDD.

INTRODUCTION

Background on Major Depressive Disorder (MDD): Major Depressive Disorder (MDD) is identified as a significant global health issue, acknowledged by the World Health Organization as a primary contributor to worldwide disability. Approximately 4% of the population suffers from depression, comprising 5.7% of adults (4.6% of men and 6.9% of women), and 5.9% of individuals over 70 years and older[1]. Approximately 9 million in India and 60 million individuals globally died from depression and its effects on health [2]. MDD is marked by enduring poor mood, anhedonia, notable alterations in food or sleep, and severe cognitive dysfunction, placing a considerable strain on both patients and healthcare systems [3].The neurological foundations of the illness are intricate, frequently encompassing structural and functional irregularities within essential brain circuits, especially those governing emotion and cognition, such as the prefrontal cortex-limbic network. Figure 1 shows the brain regions associated with the depression with their intended functions. Table 1 depicts the detailed description of the brain regions affected due to depression. MDD is often linked to reduced activity in the left dorsolateral prefrontal cortex (DLPFC) and increased activity in adjacent limbic areas [4].

Standard interventions for MDD predominantly consist of medications (antidepressants) i.e., Tricyclic antidepressants (TCAs), Selective serotonin re-uptake inhibitors (SSRIs), Selective serotonin noradrenaline re-uptake inhibitors (SNRIs) and psychotherapy [5]. Although useful for numerous individuals, these methods are not universally successful due to the disorder's variability, variations among individual patients (genetics, comorbidities, psychosocial factors), treatment-related challenges (adherence, side effects, insufficient dose), and the intrinsic limits of existing therapies. A significant concern persists regarding the high incidence of treatment-resistant depression (TRD), with nearly one-third of patients not attaining remission after sufficient trials of various drugs[6].Moreover, numerous patients who do react encounter dose-limiting adverse effects, inadequate adherence, or relapse. This significant therapeutic void has prompted an urgent quest for safe, well-tolerated, and highly targeted alternative therapies that can precisely modulate aberrant brain activity. This need highlights the increasing interest in non-invasive brain stimulation (NIBS) methods, primarily transcranial direct current stimulation (tDCS).

The Biophysical Foundation of Transcranial Direct Current Stimulation (tDCS): Mechanism, Parameters, and Subthreshold Neuronal Modulation

Transcranial Direct Current Stimulation (tDCS) is characterized as a non-invasive brain stimulation (NIBS) method that employs a steady, low-intensity direct electrical current administered via electrodes positioned on the head. This technique exemplifies a potent modality of neuro modulation, affecting neuronal function and thereby modifying behavioral results. tDCS is fundamentally different from earlier non-invasive methods due to the principles governing current delivery. Transcranial Direct Current Stimulation (tDCS) employs a steady, unidirectional direct current (DC), in contrast to the alternating current (AC) utilized in Cranial Electrotherapy Stimulation (CES) or the generated magnetic field applied in Transcranial Magnetic Stimulation (TMS). This reliance on direct current is crucial, as it enables the persistent electrical biasing of neuronal membranes, which is important to its modulatory actions. The clinical and academic interest in tDCS is driven by its advantageous characteristics compared to other neuro modulation techniques: its relative safety, portability, cost-efficiency, and simplicity of use. These attributes have facilitated its application across various study domains, including cognitive neuroscience and neuro

rehabilitation. Historically, tDCS was created to assist patients in recovering from brain injuries or treating neuropsychiatric disorders, including major depressive disorder. Current clinical research encompasses a diverse array of indications, including depression, schizophrenia, chronic pain (such as migraine and fibromyalgia), addiction, aphasia, epilepsy, and motor rehabilitation.

Significant research progress confirms increasing evidence for the efficacy of tDCS in treating major depressive disorder. Moreover, there is growing corroborative evidence for its effectiveness in addressing particular symptoms of schizophrenia, especially negative symptoms. In addition to clinical uses, tDCS is being studied for non-medical wellness purposes, including speeding up learning, improving focus, and encouraging relaxation. However, the rapid expansion of research has led to heterogeneity in outcomes. The scientific literature provides inconclusive evidence about the efficacy of tDCS in augmenting cognitive function in healthy individuals, mitigating memory impairments related to Parkinson's and Alzheimer's diseases, or boosting motor function in the aftermath of a stroke. An expert evaluation corroborates this variability, specifically highlighting inconclusive results for mild cognitive impairment and Alzheimer's type dementia. The excellent accessibility and adaptability of tDCS protocols facilitate widespread and frequently expedited adoption across various domains, including clinical neurology, psychiatry, and sports science. This diversity in study, although advantageous, leads to discrepancies among populations, stimulation parameters, and primary outcome measures. Consequently, there is a recognized necessity to ground clinical therapy in a thorough comprehension of the underlying mechanism, especially when empirical application may occasionally predate comprehensive mechanistic consensus. Moreover, it is noted that tDCS is often integrated with behavioral or cognitive training frameworks. If tDCS were only a short-term electrical effect, there would be no need for continuous training to achieve lasting behavioral improvements [12]. The amplification of training effects and enhancement of synaptic plasticity by tDCS strongly indicate that its principal function is not to initiate performance, but to alter brain states, thereby improving neural networks for subsequent learning and motor control [13]. This makes tDCS a real neuro modulatory tool that helps the cortex better process information that comes from within the body.

Current Density and Electrode Montage

The current intensity in milliamperes (mA) is the main way to quantify charge flow, but the current density (J), which is the current divided by the electrode surface area (J = I/A), is what affects cortical neurons. Current density is possibly the most important factor that controls the strength of the electric field that reaches the cortex. Electrodes used in experiments usually have a surface area of 25 cm^2 to 35 cm^2 [14]. The median current density observed is about 0.04 mA/cm^2 given this size range and the 1 mA to 2 mA intensity [14]. It is important to keep current density within a safe and useful range. For example, a low current applied to a dangerously small electrode surface would cause excessive current density and could injure tissue. The montage, or placement of the electrodes, is very important since it controls the direction of the electric field vector at the target cortical region. The 10/20 EEG system tells you where to put the anode and cathode for standard tDCS. Putting one electrode over the primary motor cortex (M1) and the reference electrode over the supraorbital fossa (SO) is a common montage [15]. Another common montage is putting electrodes on both sides of the bilateral dorsolateral prefrontal cortex (DLPFC)[16]. The current goes straight from the anode to the cathode, going through the scalp, skull, cerebrospinal fluid (CSF), and finally reaching the cortex.

Typical Duration and Safety Context

Most study uses a set amount of time for stimulation, which is the amount of time needed to start lasting changes in the body. The median length of continuous stimulation is 20 minutes, which is the length employed in 80% of study papers. It is safe for people to use protocols that use 1 mA to 2 mA for up to 20 min[17]. Safety profiles are very good, as long as the charge density stays low. Charge density, which is measured in Coulombs per area (C/cm^2), is the total charge delivered over time (Q = J × T). In most research methods, charge densities are between 0.03 C/cm^2 and 0.09 C/cm^2. Side effects are usually modest and go away on their own. They can include itching, a burning feeling at the electrode site, or a headache. The necessity for several minutes of continuous current (usually 20 min) to effect

enduring alterations in neuronal excitability underscores that the aim of tDCS is not the temporary triggering of action potentials, but the continual facilitation of slower, plasticity-associated mechanisms[18].

The Core Mechanism: Subthreshold Modulation of Neuronal Excitability

The primary mechanism of tDCS is the weak electric field eliciting subthreshold alteration of the neuronal membrane potential.This is the immediate effect of continuous direct current on cortical neurons. The low-intensity direct current infiltrates the outer tissue layers and reaches the cerebral cortex, where it alters the membrane polarity of certain neurons[19]. The current intensity is typically mild (1 mA to 2 mA), rendering the produced electrical field insufficient to independently initiate an action potential (AP). Instead, it discreetly modifies the neuron's resting membrane potential (RMP). This modification is referred to as subthreshold modulation. By modifying the resting membrane potential (RMP), transcranial direct current stimulation (tDCS) alters the neuron's operational point, either advancing it toward or retreating it from the electrical threshold necessary for action potential generation[20]. This process does not supplant the brain's inherent signaling framework; instead, it modulates the likelihood that a neuron will discharge in reaction to its typical, endogenous synaptic inputs[21]. Consequently, tDCS is regarded as neuro modulatory due to its capacity to subtly alter the bias of the neuronal network, enhancing either excitability or inhibition[21]. The instantaneous electrical effects of tDCS are solely contingent upon the polarity of the active electrode in relation to the target region. The anode's presence over the target area typically induces membrane depolarization[22]. This alteration brings the resting membrane potential nearer to the action potential threshold[23]. This results in heightened spontaneous firing and overall excitability of cortical neurons during stimulation. In contrast, positioning the cathode above the target location induces membranehyperpolarization[22][23]. This alteration increases the resting membrane potential's distance from the action potential threshold, hence diminishing the neuron's responsiveness to excitatory stimuli.This indicates reduced neuronal firing and excitability.The direct current flow—from anode to cathode—modifies neuronal electrical activity, hence affecting synaptic efficiency.

Biophysical Context and Pyramidal Neuron Modeling

The identified polarity-dependent effects are closely associated with the architecture of cortical neurons, namely the big, elongated pyramidal neurons that create columnar structures aligned perpendicularly to the cortical surface[24]. To effectively alter cortical excitability, computational modeling indicates that the electric field produced by the tDCS montage must be oriented predominantly perpendicular to the cortical surface. When the field is orthogonal, the direction of the current determines the polarization of the cellular components: Inward electric fields typically lead to preferential depolarization of pyramidal somas, consistent with the effects reported during anodal stimulation[25].Outward electric fields typically correspond to preferential hyperpolarization of pyramidal somas, consistent with the effects reported during cathodal stimulation[25]. Nonetheless, the brain's markedly diverse conductivity (scalp, skull, cerebrospinal fluid, gray matter) adds complexity[26]. The current density is heterogeneous, and not all neurons receive the current field at a precise right angle to their axes. The literature recognizes that the basic principle of "Anodal = Excitatory" and "Cathodal = Inhibitory" is not universally applicable, especially in the context of intricate electrode arrangements. Assemblies that generate an electric field parallel to the cortical surface may produce intricate polarization patterns in which neither depolarization nor hyperpolarization predominates at the soma, potentially leading to subtle or contradictory alterations in excitability. This requires computational models to precisely predict the physiological effects of various montages[27].

Mechanisms of Lasting Change: Synaptic Plasticity

The alteration in resting membrane potential (RMP) is the immediate effect of tDCS, while the prolonged behavioral and clinical outcomes, frequently persisting for minutes or hours post-current cessation, are influenced by gradual, downstream cellular mechanisms collectively referred to as neuroplasticity[13]. The persistence of therapeutic effects post-current cessation cannot be attributed solely to temporary electrical alterations. The enduring effects are regulated by the neuroplasticity paradigm, which asserts that the continuous, subthreshold modulation of resting membrane potential serves as a conditioning signal that alters local neural connections. The usual length of 20 minutes for continuous current is not arbitrary; it signifies a minimum requisite dose to initiate the sustained

signaling cascades essential for these structural and molecular alterations[28]. These synaptic alterations promote or impede local neuronal transmission, eventually augmenting or reducing synaptic efficacy.

Anodal stimulation, by keeping cortical neurons in a depolarized state just beneath the firing threshold, fosters conditions favorable for Long-Term Potentiation (LTP)[29].Long-term potentiation (LTP) refers to the enduring enhancement of synaptic connections, often regarded as a biological foundation for learning and memory. The prolonged depolarization augments synaptic transmission and facilitates the production of cerebral chemicals linked to synaptic alterations. Anodal tDCS produces an LTP-like effect in the cortex, resulting in augmented synaptic effectiveness, enhanced learning and memory capabilities, and elevated dendritic spine density. These modifications enhance efficiency in motor control, motor learning, and movement execution, partially due to enhanced regional cerebral blood flow (rCBF) and heightened neuronal metabolic activity in certain areas[30]. Cathodal stimulation, by keeping the target neurons in a hyperpolarized state, facilitates conditions conducive to Long-Term Depression (LTD)[13]. LTD refers to the persistent decrease in synaptic effectiveness. These synaptic alterations result in a functional suppression of local neuronal transmission and a consequent reduction in synaptic efficacy.

The lasting effects of tDCS are significantly influenced by traditional neurotransmitter pathways associated with plasticity. Glutamate (Glu), the principal excitatory neurotransmitter in the brain, is fundamentally associated with the regulation of receptors essential for eliciting long-term potentiation (LTP) and long-term depression (LTD) effects[31]. This reliance is supported by research integrating tDCS with pharmaceutical compounds. For example, the integration of tDCS with NMDA receptor partial agonists (such D-cycloserine) modifies the resulting excitability alterations, so validating that the enduring effects of tDCS are realized through engagement with known molecular plasticity pathways[32]. The promotion of these structural and chemical alterations (e.g., increased dendritic spine density) verifies that the electrical input results in a quantifiable, enduring change in the physical connectivity framework of brain networks. In addition to individual synaptic alterations, tDCS also affects extensive functional organization. It regulates synchronization and topological functional organization by modifying certain frequency bands, such as producing enduring facilitatory effects on high-frequency gamma oscillations after anodal tDCS[33].

tDCS application regions for depression:

The principal brain region targeted by Transcranial Direct Current Stimulation (tDCS) for the treatment of major depressive disorder (MDD) is the Dorsolateral Prefrontal Cortex (DLPFC)[35]. The justification for focusing on the DLPFC arises from the concept that depression correlates with an activity imbalance in the prefrontal cortex, particularly, reduced activity in the LDLPFC and augmented activity in the RDLPFC[36]. The predominant electrode configuration (montage) for tDCS seeks to rectify this imbalance: Anode (Positive Electrode) typically positioned above the LDLPFC (equivalent to the F3 location in the International 10-20 system). Anodal stimulation often enhances cortical excitability and neuronal activity. Cathode (Negative Electrode): Frequently positioned over the contralateral supraorbital region (the dermis above the right eyebrow) or the RDLPFC. Cathodal stimulation is believed to reduce cortical excitability. The objective is to concurrently augment activity in the hypoactive LDLPFC and/or diminish activity in the overactive RDLPFC, so reestablishing equilibrium in the prefrontal network linked to mood regulation. Subcortical regions such as the amygdala and hippocampus are implicated in emotional processing and the stress response. HD-tDCS, employing numerous tiny electrodes, is being investigated to more precisely target deep-seated regions. Research indicates it can create structural alterations in areas such as the contralateral dorsolateral prefrontal cortex, posterior cingulate cortex, and hippocampus. Schematic representation of the figure 2 depicting the utilization of transcranial direct current stimulation (tDCS) for neuromodulation in major depressive disorder (MDD). The anodal electrode (+) is situated over the left dorsolateral prefrontal cortex (DLPFC), linked to cognitive regulation and executive function, whilst the cathodal electrode (–) is positioned over the opposing frontal region to finalize the current pathway. A low-intensity direct current is administered via scalp electrodes to regulate cortical excitability and neural network activity. The sagittal view of the brain emphasizes critical areas associated with Major Depressive Disorder (MDD), such as the left dorsolateral prefrontal cortex (DLPFC), anterior cingulate cortex (involved in emotion regulation), amygdala (responsible for emotional processing and fear response), and

subgenual anterior cingulate cortex (SgACC; involved in mood regulation). The modulation of these interrelated cortico-limbic circuits correlates with alleviation of depressive symptoms, including sorrow, weariness, and apathy.

The Problem of Variability

Despite ten years of clinical research, transcranial direct current stimulation (tDCS) is associated with inconsistent results for depression. Meta-analyses reveal that certain trials demonstrate substantial symptom alleviation compared to sham, whilst others do not reproduce these findings or show only minimal advantages [37], [38], [39]. The conflicting results underscore a significant concern in the field: the problem of variability, which refers to the discovery that individuals exhibit dramatically diverse neurophysiological and clinical responses to similar stimulation protocols. A prominent hypothesis ascribes this inconsistency to inter-individual anatomical heterogeneity, which significantly influences the delivery of the applied current to cortical targets. Differences in skull thickness, cerebrospinal fluid (CSF) distribution, cortical folding patterns (gyrification), and the gray-to-white matter ratio all affect the induced electric field (E-field) in the brain[40], [41], [42]. The identical electrode configuration (e.g., F3–Fp2 for left DLPFC stimulation) and current intensity can produce variations in E-field magnitude of 2–3 times among individuals, resulting in diverse cortical modulation and clinical results.

Recent computer modeling studies have measured this variability utilizing individual MRI-derived head models. Laakso et al. revealed that the electric field strength in the left DLPFC can fluctuate by over 50% among individuals when utilizing normal 2 mA tDCS methods [43]. Evans et alsimilarly discovered that this variability was associated with alterations in cortical excitability and the extent of clinical response in patients with depression [44]. These data substantiate the concept that a standardized tDCS dosage does not correspond to a uniform neuronal effect. To illustrate this, individualized MRI-based computational modeling was performed for three representative subjects using a standard F3–Fp2 tDCS montage at 2 mA. As shown in Figure 3, the simulated E-field maps revealed >50% variability in mean E-field strength within the left dorsolateral prefrontal cortex (DLPFC) across individuals. While Subject 1 exhibited a peak E-field intensity of 0.8 V/m, Subject 3's E-field was only 0.4 V/m despite identical stimulation parameters. Such disparities suggest that fixed-dose stimulation protocols may result in suboptimal or inconsistent cortical engagement across patients.

Role of Computational Modeling (SimNIBS)

Computational modeling is essential for connecting stimulation settings with their physiological impacts on the human brain. Due to the difficulties associated with direct measurement of electric fields (E-fields) in vivo, Finite Element Modeling (FEM) offers a robust computational framework for estimating the propagation of currents through the intricate anatomy of the cranium. FEM partitions the three-dimensional head volume into numerous small elements (tetrahedra), resolving Maxwell's equations inside each element to forecast local electric field magnitudes and orientations. This approach captures the non-homogeneous, anisotropic conductivity of biological tissues, which is necessary for precise modeling of brain stimulation effects. SimNIBS (Simulation of Non-Invasive Brain Stimulation) implements Finite Element Method (FEM) for neurostimulation research. SimNIBS, utilizing open-source tools like Gmsh and GetDP, creates personalized head models from structural MRI (T1- and T2-weighted) and diffusion MRI data. MRI scans are automatically split into tissue compartments—scalp, skull, cerebrospinal fluid (CSF), gray matter, and white matter—utilizing software such as FreeSurfer or CAT12. Each tissue type is assigned conductivity values according to established literature standards (e.g., scalp: 0.465 S/m, skull: 0.01 S/m, CSF: 1.65 S/m, gray matter: 0.275 S/m, white matter: 0.126 S/m), or, when applicable, anisotropic tensors obtained from diffusion-weighted imaging (DWI) to represent the direction-dependent conductivity of white matter tracts [45], [46].

After defining the mesh and conductivity parameters, SimNIBS numerically resolves the Laplace equation for the electric potential within the head model, utilizing the designated electrode or coil placement as boundary conditions. The outcome is a high-resolution three-dimensional representation of the electric field's magnitude and orientation within the brain. Researchers can analyze electric field strength distributions on cortical surfaces, retrieve quantitative data from specific locations, and compare stimulation focality across various montages. This facilitates

the customized customization of stimulation parameters—adjusting electrode size, placement, and strength to attain the intended cortical targeting while reducing off-target effects. SimNIBS facilitates accurate and reproducible modeling of brain stimulation by merging Finite Element Method (FEM) with subject-specific MRI data, hence enhancing experimental design and clinical application. This tool has emerged as an essential instrument in computational neurostimulation research, facilitating investigations into tDCS, TMS, and transcranial alternating current stimulation (tACS), while aiding the formulation of personalized, data-informed protocols for neuromodulation.

Objectives of the review

This review primarily aims to evaluate the clinical evidence endorsing transcranial direct current stimulation (tDCS) as a treatment for depression, emphasizing the incorporation of computational modeling to improve its accuracy and effectiveness. The study aims to delineate the methodology of Finite Element Modeling (FEM) utilizing SimNIBS to quantify personalized electric field (E-field) distributions in the brain, thereby clarifying the mechanisms that underlie tDCS effects. This research synthesizes recent work to emphasize the importance, significance, limitations, and future possibilities of implementing individualized, model-based stimulation methods in clinical neuropsychiatry. This thorough analysis aims to connect clinical outcomes with biophysical modeling discoveries, establishing a framework for precision neuromodulation in depression treatment.

tDCS Efficacy in Depression: A Clinical Overview

Standard Protocol and Targets:

Transcranial Direct Current Stimulation (tDCS) has emerged as a viable neuromodulatory strategy for Major Depressive Disorder (MDD), especially focusing on the dorsolateral prefrontal cortex (DLPFC), a region associated with mood regulation, cognitive control, and emotional processing. The predominant stimulation montage utilized in clinical trials and research positions the anodal electrode at F3 (left DLPFC) and the cathodal electrode at Fp2 (right supraorbital region), in accordance with the 10–20 EEG system. An alternate configuration sometimes utilized is anode F3–cathode F4, aimed at bilateral prefrontal areas [47]. Standard stimulation parameters comprise a current intensity of 1–2 mA, applied for 20–30 minutes per session, over the course of 10–20 sessions either daily or on alternate days. Anodal stimulation of the left DLPFC aims to enhance cortical excitability, while the cathodal location functions to stabilize or diminish excitability in the contralateral prefrontal area. This polarity-dependent modulation corresponds with electrophysiological theories of cortical plasticity, wherein anodal tDCS depolarizes neuronal resting membrane potentials, enhancing neural firing, while cathodal tDCS hyperpolarizes them, suppressing excitatory activity.

The neurobiological justification for this montage arises from consistent neuroimaging findings that demonstrate functional hypoactivity in the left dorsolateral prefrontal cortex (DLPFC) and relative hyperactivity in the right DLPFC in patients with depression [48]. This interhemispheric disparity leads to compromised emotional regulation and dysfunctional affective processing. Transcranial direct current stimulation (tDCS) seeks to restore asymmetry cortical activation by augmenting excitability in the left dorsolateral prefrontal cortex (DLPFC) and diminishing the dominance of right prefrontal activity, therefore easing depression symptoms and boosting cognitive-emotional integration. This modulation is believed to affect dispersed brain networks associated with mood, attention, and executive control, encompassing fronto-limbic and fronto-striatal circuits.

Review of Meta-Analyses and Key Trials

In the last ten years, a growing corpus of clinical research has assessed the effectiveness of transcranial direct current stimulation (tDCS) as a therapeutic intervention for Major Depressive Disorder (MDD). Results consistently indicate antidepressant effects relative to sham stimulation; nevertheless, effect sizes are often small and variable, reflecting differences in trial design, stimulation parameters, and patient characteristics. The ELECT-TDCS trial[47], a significant large-scale study, including 245 patients with unipolar depression in a three-arm, double-blind, randomized controlled design that compared active tDCS, sertraline, and placebo. The findings indicated that tDCS markedly alleviated depression symptoms relative to sham, with the most substantial enhancement noted in the

combination group (tDCS + sertraline), implying an additive or synergistic interaction between neurostimulation and medicine. Nonetheless, tDCS alone demonstrated limited efficacy, with response rates inferior to those generally documented for antidepressant medications. Subsequent meta-analyses have corroborated these findings. Moffa et al. conducted a comprehensive evaluation that aggregated data from over 25 randomized controlled trials (RCTs) with more than 1,200 participants, demonstrating a significant advantage of active tDCS over sham in alleviating depression symptoms (Hedges' g = 0.35–0.40) [49]. Razza et al. also reported a response rate of roughly 45% for active tDCS compared to 27% for sham, however remission rates were very modest at around 25% [50]. Notwithstanding these promising outcomes, significant between-study heterogeneity ($I^2 > 50\%$) suggests that treatment responses differ markedly due to variables such as stimulation site precision, session frequency, concomitant medication, and initial depression severity.

Significantly, long-term follow-up data are still scarce. Research indicates that whereas immediate symptom reductions are significant, the effects of maintenance frequently wane in the absence of ongoing or supplementary sessions [51]Thus, the use of computational modeling techniques—such as personalized electric field simulations with SimNIBS—is increasingly recommended to diminish variability by guaranteeing uniform and effective cortical activation among individuals.Table 4 summarizes pivotal clinical trials published from 2021 to 2025 examining the conventional tDCS montage aimed at the left dorsolateral prefrontal cortex (DLPFC) (anode at F3, cathode at Fp2 or F4) for the management of Major Depressive Disorder (MDD). In numerous randomized controlled trials and translational studies, the stimulation parameters were predominantly uniform—generally 2 mA intensity for 20–30 minutes per session, delivered over several weeks. These findings collectively affirm the effectiveness and dependability of the bifrontal (F3–Fp2/F4) configuration in alleviating depressive symptom severity, with outcomes indicating moderate clinical improvement to substantial reductions on standardized depression scales like HAM-D and MADRS. Furthermore, recent data from tele-supervised and home-based trials [52], [53] underscore the increasing viability of remotely administered procedures while preserving the fundamental neurophysiological objective. Despite variability in response amplitude between studies, the convergent data endorses the left-anodal DLPFC montage as the standard configuration for clinical and mechanistic research on tDCS for depression.

Modeling tDCS with SimNIBS for Depression Patients

Principles of tDCS Modeling

Transcranial Direct Current Stimulation (tDCS) modeling offers a computational framework to forecast the distribution of applied electrical currents within the human cranium. This modeling is essential for optimizing electrode configurations, comprehending field focality, and guaranteeing safety and repeatability in clinical and experimental treatments. The predominant computational technique employed is the Finite Element Method (FEM), which facilitates accurate assessment of current density and electric field (E-field) distributions inside intricate head geometries obtained from MRI or CT imaging data [57], [58].

The core governing equation for modeling tDCS is the steady-state Laplace equation: $\nabla\cdot(\sigma\nabla\phi)=0$

Here, σ represents the electrical conductivity of the tissue, and ϕ denotes the electric potential. Once the potential field is solved, the electric field is computed as $E = -\nabla\phi$. This equation is solved numerically across different tissue compartments—skin, skull, cerebrospinal fluid (CSF), gray matter (GM), and white matter (WM)—each with distinct anisotropic conductivity properties that critically influence current propagation [59], [60]. Contemporary FEM solvers employ sophisticated numerical methods, such as the Hybridizable Discontinuous Galerkin (HDG) technique, to enhance computational accuracy in resolving Laplace's equation on irregular anatomical models [61]. By integrating realistic boundary conditions that depict electrode-skin interfaces, these models can replicate the dispersion of injected current from the anode to the cathode through tissue layers, facilitating individualized customization of stimulation parameters. Recent advancements broaden these modeling frameworks beyond tDCS to associated neuromodulation techniques—such as spinal and transcutaneous direct current stimulation—illustrating the applicability of FEM-based Laplacian modeling for bioelectromagnetic field simulations [62]

SimNIBS pipeline

The SimNIBS (Simulation of Non-invasive Brain Stimulation) pipeline offers a standardized, open-source framework for the personalized modeling of electric field (E-field) distributions produced by transcranial direct current stimulation (tDCS) and analogous methods. It amalgamates MRI-derived anatomical data with finite element method (FEM) solvers to attain anatomically precise field estimations [63]

Step 1: MRI Input

The procedure commences with high-resolution structural MRI scans, generally encompassing both T_1-weighted and T_2-weighted images. These pictures offer supplementary tissue contrast and spatial detail essential for precise segmentation of cerebral and non-cerebral tissues [64] In clinical or research environments, these MRI inputs undergo preprocessing to eliminate artifacts and guarantee co-registration prior to segmentation.

Step 2: Generation of Head Model

SimNIBS utilizes automatic tissue segmentation to partition the cranial volume into principal compartments: scalp, skull, cerebrospinal fluid (CSF), gray matter (GM), and white matter (WM). Segmentation is executed with integrated tools such as FSL, SPM, or FreeSurfer, followed by the tessellation of segmented tissues into a 3D finite element mesh employing Gmsh, a fundamental aspect of SimNIBS for mesh production [65], [66].

Step 3: Assignment on Conductivity

Each tissue compartment is allocated an isotropic conductivity value (σ), often adhering to recognized literature norms such as: Skin conductivity: 0.465 S/m, Skull conductivity: 0.010 S/m, CSF: 1.654 S/m, Gray Matter: 0.275 S/m, White Matter: 0.126 S/m. The default variables in SimNIBS can be modified for individualized modeling or specific pathophysiological circumstances [67]

Step 4: Simulation

After defining electrode positions, current intensities, and conductivities, SimNIBS executes an FEM-based Laplace equation solver: $\nabla\cdot(\sigma\nabla\phi)=0$ where ϕ is the electric potential. The solver computes the E-field magnitude (V/m) and vector direction throughout the brain volume. Outputs include quantitative maps and visualizations of field strength, enabling precise evaluation of target engagement and current focality[68], [69]. Figure 4 presents a step-by-step visual overview of the computational workflow used to model electric fields generated by transcranial direct current stimulation (tDCS) using SimNIBS software mentioned above.

Patient-Specific Modeling in Depression

In the realm of Major Depressive Disorder (MDD), individualized computational modeling is essential for enhancing transcranial direct current stimulation (tDCS) therapy. In contrast to generalized head models, tailored FEM-based simulations employ each patient's specific T_1- and T_2-weighted MRI scans to create anatomically accurate head models. This method considers individual anatomical variances that are especially pertinent in depression, where gray matter (GM) and white matter (WM) volumes may vary considerably due to disease-related structural changes [70], [71] Studies demonstrate that Major Depressive Disorder (MDD) is associated with reduced cortical thickness and gray matter volume, especially in the prefrontal cortex and limbic regions—targets frequently treated with transcranial direct current stimulation (tDCS) [72] These structural changes can significantly influence current flow distribution, requiring patient-specific electric field modeling to guarantee precise dose administration and therapeutic engagement of target areas [73] By identifying these individual differences, computer models provide adaptive targeting and dose optimization, hence enhancing therapeutic outcomes in treatment-resistant depression [74]Furthermore, the amalgamation of patient MRI data with machine-learning-augmented modeling frameworks facilitates predictive treatment customization, tailoring stimulation parameters to each patient's distinct neuroanatomy and pathology [72]

The Importance of E-Field Modeling for Outcomes

Linking E-Field to Clinical Response

Recent computational modeling studies have demonstrated a robust correlation between simulated electric field (E-field) intensity in targeted cortical regions—specifically the left dorsolateral prefrontal cortex (DLPFC) and anterior cingulate cortex (ACC)—and treatment efficacy in Major Depressive Disorder (MDD). Researchers have shown that elevated E-field magnitude in specific target regions, utilizing individual MRI-based head models and finite element simulations (mostly through SimNIBS), is associated with more significant decreases in depression symptom severity. The ELECT-TDCS clinical experiment [85]shown that E-field strength in both the DLPFC and ACC was a predictor of clinical improvement, surpassing standard current criteria. Razza et al. integrated meta-analysis with E-field modeling, demonstrating that patients with enhanced DLPFC field intensities experienced more significant antidepressant responses [78]. Simultaneously, Albizu et al. utilized machine learning on MRI-derived E-field maps, revealing that personalized field strength within the DLPFC predicted response categorization with greater accuracy than traditional stimulation dose measurements [72] The findings emphasize a crucial principle: personalized E-field intensity, rather than nominal current or electrode placement, serves as a more dependable predictor of treatment efficacy, signifying a paradigm shift in the dosing of non-invasive brain stimulation for major depressive disorder [86]

Individualized Protocol Optimization

E-field modeling has become an essential instrument for protocol optimization, facilitating customized tDCS parameterization that enhances target engagement while reducing off-target effects. Computational pipelines amalgamate MRI-derived anatomy with finite element modeling (FEM) to investigate differences in electrode positioning, current intensity, and montage setup for each patient. Csifcsák et al. illustrated how personalized models can modify electrode placement to amplify E-field intensity in the left DLPFC while preventing overstimulation of adjacent cortical regions [87]. Ruffini et al. developed optimization techniques utilizing realistic E-field modeling, facilitating the automated selection of electrode designs that provide accurate stimulation to specific brain networks [88]. Klooster et al. and Dannhauer et al. highlighted the translational potential of E-field-guided targeting in tDCS and TMS, demonstrating that personalized dosing informed by modeled E-fields improves efficacy and reproducibility [74], [84].

Significance of tDCS Modeling

Recent advancements in computational modeling of transcranial direct current stimulation (tDCS) have revolutionized the understanding of stimulation dose, electrode positioning, and therapy customization among academics and clinicians.

Personalization: Advancing Beyond the 10–20 EEG Framework

The conventional electrode placement with the 10–20 EEG technique overlooks individual differences in cranial thickness, cortical convolutions, and tissue conductivity. Contemporary finite element modeling (FEM) facilitates patient-specific electric field (E-field) predictions based on individual MRI data. This method customizes stimulation targets and dosages according to the patient's distinct neuroanatomy, significantly enhancing targeting accuracy[89]. Tudor et al. assert that the integration of FEM-based modeling tools like SimNIBS or ROAST into clinical processes facilitates the development of subject-specific montage designs, hence enhancing repeatability across investigations [63].

Mechanism Elucidation: Quantifying the Administered Stimulus

Modeling significantly contributes to elucidating the dose–response relationship in tDCS. Although stimulation techniques have conventionally depended on applied current (mA), FEM modeling measures the real electric field strength (V/m) in targeted cortical areas. This quantification demonstrates how alterations in brain shape influence current flow and enables researchers to correlate neural excitation thresholds with behavioral and clinical responses.

Soleimani et al. illustrated the connection between local and global current flow and neuromodulatory outcomes through network-level dose–response modeling [90]. Albizu et al. employed machine learning to associate E-field

intensity maps with treatment responses in depression, enhancing the mechanistic comprehension of how electrical dosage correlates with clinical success [72].

Clinical Trial Design: Minimizing Variability and Facilitating Stratification

tDCS modeling is essential for optimizing clinical trials, enabling researchers to categorize individuals according to anticipated cortical involvement and customize protocols prior to trial commencement. This modeling-informed stratification can significantly diminish inter-subject variability, a primary constraint in earlier large-scale tDCS experiments [91]. Van Hoornweder et al. assert that including customized modeling into trial design enhances the interpretability and reproducibility of neurostimulation results [92]. Caulfield & George shown that modifying electrode shape and spacing according to model-derived E-field distributions can enhance the on-target stimulation magnitude twofold, hence directly influencing optimum clinical study parameters [93].

Limitations of SimNIBS/FEM Modeling

Although it significantly enhances the personalization of transcranial direct current stimulation (tDCS), Finite Element Method (FEM)-based modeling, especially via systems such as SimNIBS, encounters considerable technical and conceptual constraints that impact its translational reliability. A primary limitation in FEM modeling is the presumed conductivity values of tissues. These values are generally obtained from ex vivo or population-averaged datasets, rather than being assessed in vivo. Variability in conductivity among persons, influenced by age, hydration, disease, and temperature, generates significant variability in electric field estimations [94], [95]. Wang et al. observe that although SimNIBS permits multi-tissue conductivity assignment, its dependence on static, isotropic characteristics frequently results in an inadequate representation of physiological variability in white matter anisotropy and cerebrospinal fluid conductance [96]. FEM simulations regard the head as a static, passive medium, failing to consider dynamic physiological alterations such as cerebral blood flow, metabolic coupling, synaptic plasticity, or brain state-dependency. Consequently, models can forecast current flow but cannot accurately represent neural modulation or time-varying network responses. High-fidelity modeling necessitates individual MRI scans, segmentation of various tissues, and high-resolution meshing, potentially comprising millions of elements. This incurs considerable computing expense and duration, frequently restricting the application of modeling pipelines to research settings instead of clinical practice. Recent comparisons indicate that contemporary hybrid solvers or reduced-order models can enhance efficiency, however they are still undergoing validation [97]. Standard SimNIBS models typically have five to six tissue compartments: skin, skull, cerebrospinal fluid (CSF), gray matter, white matter, and occasionally air spaces. This simplification neglects intricate anatomical components, including vascular, dura, adipose layers, and subcortical heterogeneities, which might affect current flow routes. Gomez-Tames et al. further shown that even little variations in segmentation algorithms or mesh density can produce significant discrepancies in local E-field magnitude estimations, highlighting the necessity for uniform modeling protocols [98].

Future Directions

The future of tDCS modeling involves the integration of multimodal data, the enhancement of targeting precision, and the improvement of clinical accessibility. Recent developments in hybrid brain modeling (HBM) integrate E-field simulations with fMRI and EEG to more accurately elucidate how stimulation modifies functional brain networks in real time[99], [100]. Advancements in high-definition transcranial direct current stimulation (HD-tDCS) and temporal interference (TI) stimulation now permit precise, depth-selective targeting of deeper structures, including the anterior cingulate cortex (ACC), a critical area associated with depression[101], [102]. Efforts are being made to develop streamlined, clinically applicable modeling pipelines that can estimate personalized head conductivities using minimal MRI or demographic data, thereby lowering computational obstacles for regular implementation[103]. Collectively, these advancements signify a transition towards adaptable, individualized, and therapeutically applicable tDCS modeling frameworks, connecting computational neuroscience with precision neuropsychiatry.

CONCLUSION

Transcranial Direct Current Stimulation (tDCS) is a promising non-invasive treatment for Major Depressive Disorder (MDD), but its clinical effectiveness is hindered by significant variability in individual treatment responses. Advancements in computational modeling, especially via tools like SimNIBS, have facilitated individualized, anatomically-informed stimulation planning to tackle this difficulty. Utilizing MRI-based finite element models, SimNIBS enables accurate assessment of electric field (E-field) distributions within specific brain structures, hence enhancing the optimization of electrode configurations, current intensities, and target engagement. Furthermore, the continuous amalgamation of modeling with functional imaging (fMRI, EEG) and the advent of high-definition and deep-targeting procedures are broadening the potential of tDCS for more efficacious and personalized neuromodulation approaches. The ongoing refining and clinical application of E-field modeling are essential for improving the reliability, efficacy, and personalization of tDCS in the treatment of depression.

Table: 1 Brain regions affected in the depression with their associated changes and symptoms

Brain Region	Typical Changes Observed	Associated Symptoms
Prefrontal Cortex (PFC)	Decreased gray matter volume and cortical thickness, particularly in the dorsolateral prefrontal cortex (dlPFC) and orbitofrontal cortex (OFC) regions[7].	Deficient decision-making, attentiveness, and emotional regulation; adverse thoughts and rumination.
Hippocampus	Reduced volume, diminished neurogenesis, and loss of synaptic connections[8].	Memory deficits, compromised learning, and an inability to modulate the stress response.
Amygdala	Frequently exhibits heightened activity and blood flow in reaction to adverse stimuli; alterations in volume are inconsistent, with some studies indicating a drop, while others claim an increase or no variation[9].	Intensified negative feelings, anxiety, and the acquisition of dread.
Cingulate Cortex	Decreased volume and modified activity, especially in the anterior cingulate cortex (ACC), which is involved in mood management and cognitive functions[10].	Challenges in emotional regulation and heightened self-referential rumination.
Striatum	Reduced gray matter density associated with the brain's reward system[11].	Anhedonia, characterized by an inability to experience pleasure, accompanied by diminished desire and a decrease in reward-seeking behaviour.

Table: 2 Consensus Parameters for Clinical and Research tDCS Protocols.

Parameter	Typical Range	Median Value (Research)	Biophysical Significance
Current Intensity (I_{tDCS})	1.0 to 2.0 mA	1. mA	Figures out how much charge was added to the circuit.
Electrode Size (A)	25 cm^2 to 35 cm^2	N/A	Affects skin contact resistance, which is important for figuring out current density.
Current Density (J = I/A)	0.03 to 0.09 mA/cm^2	0.04 mA/ cm^2	The main factor that determines the strength of the local electric field at the surface of the cortex.
Duration of Stimulation (T)	Up to 20 min	20 min	The least amount of time needed to make long-term synaptic plasticity effects happen.
Charge Density (Q = J×T)	0.03 to 0.09 C/cm^2	N/A	Total charge given; the main safety measure for stopping tissue damage.

Table: 3 Biphasic Mechanism of Action in tDCS.

ABSTRACT

Alzheimer's disease (AD) is a progressive neurodegenerative disorder that causes cognitive decline and requires reliable identification of different disease stages for effective clinical assessment. Brain magnetic resonance imaging (MRI) provides structural information that supports computer-aided AD classification. However, existing approaches encounter challenges associated with MRI noise, high-dimensional and redundant features, computational complexity, inefficient feature optimization, and reliable multiclass prediction. To address these problems, this research proposes the Discriminative Normalized Fireworks Optimization Network (DNFON) for optimized multiclass AD classification. DNFON integrates a Double Window Median Filter for noise removal, Min–Max Pixel Normalization and Z-Score Standardization for consistent feature representation, Linear Discriminant Analysis (LDA) for dimensionality reduction and class discrimination, and the Fireworks Algorithm (FA) for optimal informative feature selection. The selected features are subsequently processed by a Feed Forward Neural Network (FFNN) to learn discriminative patterns and classify MRI images into different AD stages. Experimental results demonstrate that the proposed DNFON achieves an accuracy of 95.63%, outperforming the considered existing approaches. Overall, DNFON provides an effective and reliable framework for optimized MRI-based Alzheimer's disease classification.

Keywords: Alzheimer's disease, Brain MRI, Cognitive Decline, Dementia, Neurode generation, Medical Image Classification

INTRODUCTION

Alzheimer's disease (AD) classification is important for identifying cognitive decline and distinguishing different stages of neurode generation using brain MRI images. Due to variations in brain structures and disease stages, effective image processing, discriminative feature representation, feature optimization, and classification are essential for reliable AD identification. CNN architectures have been used for early MRI-based AD classification [1], while hybrid machine-learning and deep-learning approaches have been investigated to improve disease classification [2]. Deep network fusion with optimal feature selection has been applied for MRI-driven AD diagnosis [3], and optimized hybrid deep learning with adaptive weight selection has been introduced for early detection [4]. FFNN-based approaches integrating imaging and demographic information have supported multiclass dementia classification [5], whereas integrated deep-learning models have been developed for early and multiclass diagnosis from MRI scans [6]. Optimized hybrid deep-learning frameworks have also been investigated for AD detection [7], while dual CNNs with ensemble classification have been utilized to distinguish different stages of AD [8]. Different optimization and deep-learning techniques have further been explored to improve feature selection and AD prediction. Enhanced Particle Swarm Optimization (PSO) with SVM has been used for optimized feature selection in AD diagnosis [9], while Harris Hawks Optimization (HHO) with an MLP-LSTM network has been investigated for AD prediction [10].

Neuro imaging-based deep-learning frameworks have been introduced for early disease detection [11], and advanced deep-learning and ensemble techniques have been applied for AD classification [12]. Deep-learning approaches using brain MRI images have further supported AD diagnosis and classification [13], while Moth Flame Optimization (MFO), Recurrent Neural Network (RNN), and Deep Reinforcement Learning (DRL) have been combined for optimized disease classification [14]. Stacked CNNs with multichannel attention have also been investigated for AD detection [15]. However, challenges involving computational complexity, feature optimization, dimensionality, MRI variations, and efficient multiclass classification remain, motivating the development of the proposed DNFON for optimized MRI-based AD classification. This research contributes an optimized framework for multiclass Alzheimer's disease classification from brain MRI images, focusing on effective noise reduction, standardized feature representation, dimensionality reduction, and informative feature selection. It improves the discrimination of different AD stages while reducing irrelevant and redundant MRI information. The proposed framework provides an efficient and reliable approach for MRI-based Alzheimer's disease classification. The research is organized as follows: Section 2 reviews existing Alzheimer's disease detection and classification approaches. Section 3 presents the proposed DNFON methodology, while Section 4 discusses the experimental results and performance evaluation. Finally, Section 5 summarizes the findings and presents future research directions.

Background study

A. M. El-Assy et al. (2024) [1] developed a CNN-based method for early AD classification using MRI images. The model effectively learns discriminative MRI features for disease identification. However, CNN complexity creates a gap for efficient feature selection and optimized classification. H. A. Raza et al. (2024) [2] proposed a hybrid machine learning and deep learning approach for AD classification. The combination improves feature learning and disease identification. However, hybrid-model complexity indicates a need for simpler and optimized classification methods. M. U. Ali et al. (2024) [3] introduced an MRI-based AD diagnosis approach using deep network fusion and optimal feature selection. The method combines informative deep features to improve classification. However, network fusion can increase computational complexity, creating scope for efficient feature optimization. K. Gasmi et al. (2024) [4] developed an optimized hybrid deep learning model with adaptive weight selection for early AD detection. Adaptive weighting improves the contribution of useful features during classification. However, the hybrid structure creates scope for less complex feature optimization and classification.E. Y. W. Cheung et al. (2024) [5] used a Feed Forward Neural Network (FFNN) with demographic and imaging features for multiclass dementia classification. The method supports effective identification of different dementia stages. However, dependence on multiple feature types creates a gap for MRI-focused optimized feature classification.

E. R. Vinukonda and B. N. Jagadesh (2025) [6] proposed an integrated model for multiclass AD diagnosis from MRI, including improved DeepLabV3+ segmentation and LeNet-5 feature extraction. The approach improves the identification of different AD stages. However, its multi-stage architecture creates scope for a more efficient optimized feature-based model. A. S. Raj et al. (2025) [7] developed an optimized hybrid deep learning model for Alzheimer's disease detection. The method focuses on improving feature extraction and classification for early-stage identification. However, hybrid-model complexity indicates a gap for simplified optimization-based classification. S. Zolfaghari et al. (2025) [8] proposed an MRI-based AD-stage classification approach using dual CNNs and an ensemble classifier. The dual networks extract complementary information for disease-stage identification. However, multiple CNNs and ensemble processing create a gap for efficient feature reduction and simpler classification. The table 1 compares recent Alzheimer's disease classification methods, highlighting the techniques, limitations and research gaps. Existing methods often have high computational and model complexity, indicating the need for efficient feature selection and optimized MRI-based classification.

PROPOSED METHODOLOGY

This section presents the methodology for Alzheimer's disease classification using brain MRI images. It covers the Kaggle dataset, DNFON workflow, preprocessing, normalization, standardization, LDA-based feature reduction, FA-based optimal feature selection, and FFNN classification. It also presents the mathematical formulations, pseudocode, real-time applicability, and reproducibility of the proposed DNFON framework.

Dataset description

The Alzheimer MRI Dataset is obtained from Kaggle and is publicly available at https://www.kaggle.com/datasets/azminur2856/alzheimer-mri-dataset/data. It contains approximately 40,000 preprocessed brain MRI images in JPG format, organized into four classes: NonDemented, VeryMildDemented, MildDemented, and ModerateDemented. The dataset provides MRI samples representing different stages of Alzheimer's disease and is suitable for developing and evaluating the proposed DNFON-based AD classification approach.

Classification using Discriminative Normalized Fireworks Optimization Network (DNFON)

The proposed Discriminative Normalized Fireworks Optimization Network is developed for automatic multiclass AD classification using brain MRI images. It integrates Double Window Median Filter, Min–Max Pixel Normalization, Z-Score Standardization, LDA, FA and FFNN. Initially, the Double Window Median Filter removes MRI noise while preserving important brain structures. Min–Max normalization scales the pixel values into a consistent range, followed by Z-Score Standardization for standardized feature representation. LDA reduces feature dimensionality and improves discrimination among different AD classes. Subsequently, FA searches for and selects the most informative features from the reduced feature set. The optimized features are provided to the FFNN, which learns discriminative patterns and generates the final AD class prediction. For practical application, a new MRI image can sequentially pass through the DNFON pipeline to obtain its predicted disease class. However, clinical real-time deployment and inference latency are not evaluated, so real-time use remains a proposed application. For reproducibility, DNFON is executed through multiple independent runs under identical experimental conditions. Consistent classification performance across these runs indicates reduced influence of random variations. Thus, the repeated experimental behavior demonstrates the stability, reliability, and reproducibility of DNFON.

Figure 1 begins with a brain MRI image, where the Double Window Median Filter removes noise, followed by Min–Max normalization and Z-Score standardization for consistent feature representation. LDA reduces feature dimensionality and improves class separation, while the Fireworks Algorithm selects the optimal informative features. Finally, the selected features are processed by FFNN to learn disease patterns and produce the final Alzheimer's disease classification.

$$N = \frac{X - X_{\min}}{X_{\max} - X_{\min}} \quad (1)$$

Equation (1) represents$X$ is the original MRI pixel value, $X_{\min}$ is the minimum pixel value, and $X_{\max}$ is the maximum pixel value. NRepresents the normalized value obtained after scaling the MRI data. This provides a consistent input range for further processing.

$$Z = \frac{X-\mu}{\sigma} \quad (2)$$

Equation (2) represents$X$is the input feature, μ represents its average value, and σ represents the variation of the feature values. $Z$is the standardized feature obtained after transformation. This makes different MRI features comparable before feature selection.

$$D = \frac{\text{Between-Class Difference}}{\text{Within-Class Difference}} \quad (3)$$

Equation (3) D represents the discriminative score produced by LDA. The numerator measures how different the Alzheimer's classes are from each other, while the denominator measures differences among samples belonging to the same class. A higher D indicates better class separation and more useful discriminative features.

$$F_{best} = \min\big(Error(F_1), Error(F_2), \ldots, Error(F_n)\big) \quad (4)$$

Equation (4) $F_1, F_2, \ldots, F_n$ represents different candidate feature subsets generated and evaluated during the Fireworks optimization process. $Error(F_i)$Indicates the classification error associated with each candidate subset. F_{best}Represents the optimized feature subset selected based on the best evaluation result.

$$Y = f(WX + B) \quad (5)$$

Equation (5), X represents the optimized MRI features obtained from the previous stages, W represents the learned connection weights, and B represents the bias. The function f transforms the combined information into the network output. YRepresent the final predicted Alzheimer's disease class produced by DNFON.

Algorithm: Discriminative Normalized Fireworks Optimization Network (DNFON)

```
Input: Brain MRI image I
Output: Predicted Alzheimer's disease class Y
BEGIN
I_f ← Double Window Median Filter (I)
I_n ← Min Max Normalization (I_f)
  F_s ← ZS core Standardization (I_n)
F_d ← LDA (F_s)
  Initialize Fireworks population P
  WHILE termination criterion is not satisfied DO
    FOR each firework p ∈ P DO
      Generate sparks from F_d
      Evaluate fitness of generated sparks
      Select informative feature candidates
    END FOR
    Update P with best candidates
  END WHILE
F_opt ← Select optimal feature subset
  Initialize FFNN
  FOR each F_opt DO
    Compute hidden layer response
    Compute output layer response
    Update FFNN weights
  END FOR
  Y ← FFNN(F_opt)
  RETURN Y
END
```

The pseudo-code describes the DNFON workflow for MRI-based Alzheimer's disease classification. It performs preprocessing, feature reduction, optimal feature selection and FFNN classification to generate the final predicted AD class.

RESULT AND DISCUSSION

This section evaluates the proposed DNFON using Accuracy, Precision, Recall and F1-Score and compares its performance with existing methods. The results are presented through tables and graphs to demonstrate its effectiveness in Alzheimer's disease classification. Table 2 compares the classification performance of the proposed DNFON with existing methods. DNFON achieves the highest performance, where Accuracy is 95.63%, Precision is 95.21%, Recall is 94.87%, and F1-Score is 95.04%. These results demonstrate the improved overall classification performance of DNFON. The figure 2 compares Accuracy, Precision, Recall, and F1-Score of the proposed DNFON with CNN, Improved DeepLabV3+, ARO, and Enhanced PSO. DNFON achieves the highest performance with 95.63% accuracy, 95.21% precision, 94.87% recall, and 95.04% F1-score. The results demonstrate the improved and balanced classification performance of DNFON across all four evaluation metrics.

CONCLUSION

This research presented the DNFON for multiclass Alzheimer's disease classification using brain MRI images. The framework integrates image filtering, normalization, standardization, discriminative dimensionality reduction, optimal feature selection, and neural classification to provide an effective AD classification process. The experimental results showed that DNFON achieved 95.63% accuracy, 95.21% precision, 94.87% recall and 95.04% F1-score, outperforming the considered CNN, Improved DeepLabV3+, ARO, and Enhanced PSO methods. These findings indicate that the proposed approach effectively reduces irrelevant information, selects informative MRI features and provides balanced classification across the evaluation metrics. Overall, DNFON provides a reliable computational framework for distinguishing different stages of Alzheimer's disease from MRI images. Future work can focus on evaluating the framework using larger and diverse MRI datasets, improving generalization across different imaging conditions, and reducing computational requirements. Further research can also investigate multimodal clinical information, explainable prediction mechanisms, lightweight optimization strategies, and clinical validation to improve interpretability, scalability, and applicability for computer-assisted Alzheimer's disease assessment.

ABSTRACT

Yuvanpidika, described under *KshudraRoga in Sushruta Samhita,* closely resembles acne vulgaris, a chronic inflammatory disorder of the pilosebaceous unit causing considerable cosmetic and psychological distress. Ayurveda considers the condition to involve vitiation of *Kapha, Pitta and Rakta*. A 24- year -old female patient with mild papulo-pustular acne of 1.5 years duration was treated with classical Ayurvedic formulations including *Gandhak Rasayan, Arogyavardhini Vati, KaishorGuggulu* and *Laghu ManjisthadiKwath* along with external applications of *Shatdhautaghrit* and *kumkumadilepa* for 10 weeks.clinical assessment was performed using the global acne grading scale(GAGS) with periodic follow-up significant reduction in inflammatory lesion, erythema and seborrhea was observed,along with improvement in digestion and bowel habits. The GAGS score showed marked improvement within the mild category, with better skin texture and reduced recurrence. Although limited by its single-case design and lack of biochemical assessment, the study suggests that ayurvedic therapy may provide a safe and effective or adjunct in the management of mild acne vulgaris.

INTRODUCTION

*Yuvanpidika*is one of the most prevalent cosmetically disfiguring dermatological conditions encountered during adolescence & is categorised as *Kshudraroga*in the *Ayurvedic*nosological framework.[1] The nomenclature*Yuvanpidika*

is etymologically derived from the Sanskrit lexemes *Yuvan*(youth) &*pidika* (painful eruption lesion), collectively denoting tender inflammatory cutaneous eruptions predominantly manifesting during the adolescent phase. The condition is further delineated in classical literature by synonymous terminologies such as *Mukhadushika* & *tarunyapidika*.[1,2] As elucidated by *Acharya Sushruta, yuvanpidika* is typified by eruptions morphologically analogous to the thorns of *shalmali* (Bombax ceiba), primarily localised over the facial region during youth.[1,2] The etiopathogenesis is attributed to the vitiation of *kapha*&*vata* dosha in conjunction with the derangement of *Rakta dhatu*. Canonical ayurvedic compendia consistently classify this condition under the spectrum of *Kshudrarogas*, emphasising its clinical significance despite its non-fatal nature.[1,2] From the standpoint of contemporary biomedical science, *yuvanpidika* exhibits a strong clinicopathological correlation with acne vulgaris, a chronic inflammatory disorder of the pilosebaceous apparatus.[3] The condition is characterised by a polymorphic constellation of lesions, including open & closed comedones, erythematous papules, pustules & in severe cases, nodulocystic formations. The pathophysiological cascade underlying acne vulgaris is multi factorial ,encompassing sebaceous gland hyperactivity with excessive sebum production, aberrant follicularkeratinisation leading to ductal obstruction, proliferation of Cutibacterium aurum, & the subsequent induction of a complex inflammatory milieu mediated by cytokines & immune responses.[3] Therapeutic management in modern dermatology predominantly relies on pharmacological interventions such as topical & systemic retinoids, benzoyl peroxide, antimicrobial agents, and anti-androgenic therapies. Nevertheless, these modalities are frequently associated with a spectrum of adverse effects, including xerosis, irritant dermatitis, erythema, post-inflammatory hyper pigmentation and a notable propensity for relapse upon cessation of therapy. Moreover, acne vulgaris exerts a profound psychosocial burden, often precipitating emotional distress, diminished self-esteem, social inhibition, and an overall deterioration in quality of life, particularly among adolescent populations.

Patient Information

A 24-year-old female patient presented to the outpatient department with complaints of redness, burning sensation, and papular lesions all over the face for 1.5 years. Symptoms were gradually progressing after consuming the oily junk food. The patient appeared fatigued with emotional stress and reactive behaviour acting as contributing factors, and had no significant past medical history. There was no history of hormonal acne or acne associated with PCOD. She had a vegetarian diet and mild walking. She denied any history of smoking, alcohol consumption, hormonal imbalance, or hygiene issues. Before treatment, no treatment was taken.

Clinical Findings

On examination, Vital signs were stable. Site of involvement: face (cheeks, chin). Primary lesions are seen as open come dones (blackheads), papules, pustules and nodules as inflammatory lesions. Atrophic scars(ice-pick) as secondary lesions. Associated symptoms- oily skin(seborrheic), mild pain According to *Ayurvedic* assessment, the suggested *pitta–kapharaktayuvanpidika*.[1,2]

Timeline Table 1 summarises the clinical progression observed over the (10-week)2.5-month treatment period, refer to below.

Diagnostic Assessment Table 2 summarises the GAGS Score (Global Acne Grading Scale)[4,5]refer below.
Severity Classification:
1-18: Mild
19-30: Moderate
31-38: Severe
>39: Very Severe
18: Mild

Therapeutic Interventions

The detailed treatment plan is presented in Table 3 refer below.

Follow-Up and Outcomes

During 1week follow up – patient showed improved metabolic function & better bowel clearance. Results in good digestion with the therapy promoting the systemic detoxification leading to decreased inflammation, redness and recurrent lesions. Reduction in itching &eruptions suggests anti-inflammatory activity. Improvement in blood purification contributed to better skin health. Topical applications provided cooling and soothing effects.

DISCUSSION

Acne vulgaris is a multifactorial inflammatory disorder involving increased sebum production, follicular hyperker atinization, microbial colonisation, and inflammation.[4] In the present case, the patient exhibited classical features of mild papulo-pustular acne with associated seborrhea, psychological stress, and dietary triggers such as oily and junk food. From an *Ayurvedic* perspective, this condition can be correlated with *yuvanpidika* (acne vulgaris), primarily involving vitiation of *pitta,kapha* and *rakta,* along with the contribution of *Ama* & *manshika* factors like stress.[1,2] The use of *Gandhak Rasayana* is particularly well-documented for its antimicrobial, anti-inflammatory & skin rejuvenating properties.[6] Similarly. *Arogyavardhinivati* plays a crucial role in liver function correction and metabolic regulation, which may indirectly influence hormonal balance and sebum production. *Kaishor Guggulu*[7]and *Laghu manjisthadikwath*[8]are classical formulations known for their *Rakta shodhaka* (blood purification)and anti-inflammatory actions, which help in reducing erythema, papules and pustules. External applications such as *Shatdhautaghrita*[9] and *Kumkumadilepa*[10] contributed to local soothing, anti-inflammatory and scar-reducing effects. The addition of *Shankh Bhasma* may have enhanced the drying and healing properties of the formulation, aiding in lesion resolution and prevention of further eruptions.

An important observation in this case is the role of psychological stress as a contributing factor. Stress is known to exacerbate acne through hormonal pathways, particularly via increased cortisol levels, and systemic treatment may have synergistically contributed to clinical improvement. However, this is a single case study, and the findings cannot be generalised without further large-scale clinical trials objectives of biochemical or hormonal parameters were not assessed, which could have strengthened the evidence. Despite these limitations, the observations can serve as a safe and effective alternative or complementary approach in the management of acne vulgaris. In this present study, the acne vulgaris patient exhibited classical features of mild papulo-pustular acne with associated seborrhea, psychological stress and dietary triggers. The intervention of internal and external therapies results in a marked and significant improvement, which is assessed by the GAGS score.[4,5] Regulation in metabolism, proper systemic circulation and significant reduction in acne within the duration of 10 weeks of treatment give better results for skin diseased condition.

Patient Perspective-The patient expressed satisfaction with the treatment on (22/10/2025), reporting significant relief from burning, redness and itching in papulo-pustular acne. She appreciated the intervention of external therapy and the soothing effect of drug intervention, which relieves her stress conditions.

Patient Consent -Written informed consent was obtained from the patient for publication of this case report and accompanying clinical information. The signed consent form will be provided to the editor upon request.

Conflict of Interest-The authors declare that there is no conflict of interest related to this publication.

ABSTRACT

Historic monument complexes present a distinctive thermal environment in which massed masonry structures, open plazas, managed gardens, water bodies, and adjoining urban fabric are compared within a compact spatial envelope. This heterogeneity produces a fine-grained mosaic of surface temperatures that is not adequately captured by city-wide or regional urban heat island (UHI) assessments, yet is of direct relevance to heritage conservation practice, since surface heating governs material weathering, moisture cycling, and the microclimatic conditions experienced by visitors and conservators alike. The aim of the paper is to review and interprets Land Surface Temperature (LST) retrievals for the Bada Imambara complex in Lucknow, one of the largest vaulted halls of its kind in the world, together with its associated gateways, stepwell (shahi baoli), bhulbhulaiya precinct, the Asafi Mosque, and the surrounding lawns and courtyards.The analysis draws on five satellite-derived LST products clipped to the monument boundary and draped over high-resolution basemap imagery: an annual composite (01.12.2024 - 31.11.2025) and four seasonal composites corresponding to the Winter (01.12.2024-28.02.2025), Summer (01.03.2025 - 30.06.2025), Monsoon (01.07.2025 - 31.08.2025), and Post-Monsoon (01.09.2025 - 31.11.2025) periods that structure the North Indian climatic year. This paper has three linked objectives. First, it quantifies the range and distribution of LST within the heritage precinct across seasons. Second, it examines the spatial correspondence between LST patterns and the land use/land cover (LULC) elements visible within and immediately around the complex - roofed built mass, paved courtyards, vegetated lawns, water surfaces, and the surrounding urban matrix - in order to characterize the thermal signature of each cover type. Third, it discusses the biophysical and anthropogenic drivers that plausibly

account for the observed seasonal and spatial variability, and considers the implications of these findings for the conservation and micro-climatic management of the site. It should be stated that the present works from the five rendered LST maps as the primary evidential base, without an independently classified LULC raster or in-situ meteorological record for cross-validation. Land cover attribution below is therefore derived from visual co-registration of the thermal layer with the underlying high-resolution basemap and the monument's digitized footprint, and the discussion of drivers is correspondingly framed as an interpretive synthesis grounded in established thermal-remote-sensing and heritage-microclimate literature, rather than as a statistically validated causal analysis.

Keywords: Land Surface Temperature (LST), Land Use Land Cover (LULC), Hot and Cool spots, Heritage Conservation, Site Management

INTRODUCTION

Land Surface Temperature (LST) is a key biophysical variable governing the exchange of energy between the Earth's surface and the atmosphere, and it is widely recognized as a sensitive indicator of urban thermal environments, land use and land cover (LULC) change, and microclimatic stress.[1]Historic monument precincts occupy a distinctive position within this thermal landscape: they typically combine extensive impervious, stone-paved, or masonry surfaces with pockets of vegetation, water bodies, and open courtyards, all embedded within, or at the margin of, rapidly urbanizing cityscapes. [2]The combination of heat-retentive built heritage fabric and surrounding urban land cover makes heritage precincts valuable, [3]yet comparatively under-studied, sites for examining intra-urban thermal variability across seasons. This paper presents a season-wise assessment of LST across culturally significant monument complex in Uttar Pradesh, India: the Bada Imambara complex, Lucknow. Satellite-derived thermal data for the Winter, Summer, Monsoon, and Post-Monsoon seasons, together with the corresponding Annual composite, are analyzed to characterize the spatial distribution, magnitude, and seasonal amplitude of surface temperature within and around each monument precinct. This paper discusses the underlying land-cover controls on the observed thermal patterns and their implications for heritage conservation and microclimatic planning.

Rationale and Significance

Heritage structures are highly susceptible to thermal stress, which accelerates material fatigue, differential expansion-contraction of stone and masonry, salt weathering, and biological colonization of exposed surfaces.[4] Quantifying the seasonal LST regime of a monument precinct therefore carries a dual significance: first, it contributes to the broader discourse on urban heat island (UHI) dynamics within historic city cores; [5]second, it provides an empirical evidence base for site-level conservation planning, buffer-zone management, and green-infrastructure interventions intended to moderate thermal extremes around protected monuments.

Study Area

The Bada Imambara, built by Nawab Asaf-ud-Daula in 1784, lies within the dense historic core of old Lucknow. This precinct is tightly embedded within a built-up urban matrix, with narrow surrounding streets, closely spaced rooftops, and comparatively limited open vegetated land, which strongly conditions its thermal signature.

METHODOLOGY ADOPTED FOR ANALYSIS

Each of the five maps presents a continuous LST surface, resampled to a coarser thermal grid and overlaid at reduced opacity on very-high-resolution optical imagery of the complex, with the monument's built and landscape boundary digitized as a black vector outline. A common blue-cyan-green-yellow-orange-red palette is used throughout, scaled independently to the minimum and maximum LST recorded within each scene, as reported in the accompanying legend. Because the colour stretch is scene-specific rather than fixed across seasons, the palette communicates the

relative (intra-scene) thermal pattern faithfully, while absolute comparison between seasons must rely on the numeric legend values rather than colour alone. This distinction is maintained throughout the results that follow.

Annual Composite

The Annual composite (Figure 1) shows LST ranging from 31.94 °C to 33.79 °C across the site. The coolest zone (dark blue) forms a compact core in the north-central part of the complex, coinciding with the open lawn between the main entrance gateway and the great vaulted hall. Progressively warmer bands (cyan to green) extend across the mosque courtyard and colonnaded gallery to the east, while the warmest values (orange to red) are concentrated along the southern edge of the complex, in a zone of dense, elongated built structures, and in a smaller hotspot at the north-western entrance plaza adjoining the public road. The eastern wing of ancillary buildings registers intermediate-to-cool values relative to the southern block.

Summer Composite

During Summer (Figure 2), the whole complex is elevated in absolute terms, but the spatial arrangement of hot and cool zones closely mirrors the Annual pattern: the north-central lawn again forms the coolest core (dark blue, approaching 36.9 °C), while the southern built block and, to a lesser extent, the north-eastern boundary strip along the road remain the warmest features (approaching 39.5 °C). The persistence of this spatial configuration across the Annual and Summer composites suggests that the underlying land cover mosaic, rather than transient atmospheric conditions, is the principal control on the pattern, even as the overall thermal baseline shifts with season.

Monsoon Composite

The Monsoon composite (Figure 3) records the widest internal range of all five products (3.86 °C). The north-central lawn remains the coolest feature of the complex, now forming an even more sharply defined dark-blue core, consistent with soil and turf moisture enhancing evaporative cooling immediately after rainfall. In contrast, the southern built block continues to register the warmest surface temperatures, and the contrast between this block and the adjoining lawn is visually the most pronounced of any seasonal map, indicating that vegetated and paved/roofed surfaces respond most divergently to wetting during this period.

Post-Monsoon Composite

In the Post-Monsoon composite (Figure 4), the spatial signature shifts noticeably relative to the other four seasons. The warmest zone (red-orange) now occupies the north-western entrance plaza and the adjoining public street frontage, rather than the southern block, which registers only moderate (yellow-green) values in this scene. The north-central lawn and, in particular, the domed rotunda area near the mosque courtyard remains the coolest features (dark blue). This reconfiguration is consistent with a change in the sun's position and the resulting distribution of shadow and direct irradiance across the complex's built masses as the season transitions from the low, humid-season sun angles of Monsoon toward the clear, drier conditions of Winter.

Winter Composite

The Winter composite (Figure 5) records both the lowest absolute LST values and the narrowest internal range of the five products. The clearest warm feature is a band along the north-eastern boundary of the complex, adjoining the public road, which appears in the yellow-orange-red portion of the scale; the eastern wing of ancillary buildings, by contrast, records the coolest values in this season, a reversal of its intermediate standing in the other four composites. The north-central lawn remains comparatively cool but is less sharply differentiated from its surroundings than in the Summer or Monsoon scenes, consistent with the generally muted thermal contrasts of the Winter season.

RESULTS

Seasonal LST Distribution

Table 1 summarizes the minimum and maximum LST recorded within the Bada Imambara boundary in each of the five products, together with the intra-scene range - the spread between the coolest and warmest pixels within the same map - which serves as an index of internal thermal heterogeneity. Two broad patterns emerge from Table 1. First, the overall thermal level of the complex follows the expected North Indian seasonal cycle, rising from a Winter minimum (23.85–25.00 °C) through Post-Monsoon and Annual values into a pronounced Summer maximum (36.90–39.49 °C), a range of roughly 14–15 °C between the coolest and warmest seasons. Second, the internal range within a single scene is not simply proportional to the overall thermal level: Monsoon, despite recording the second-lowest absolute temperatures, exhibits the widest intra-scene spread (3.86 °C), while Winter, the coolest season overall, shows the narrowest spread (1.15 °C).

Spatial Pattern in Relation to Land Use / Land Cover

Read together, the five composites indicate a recurrent, though not entirely static, association between LST and five broad land cover classes discernible within and around the monument boundary: (i) roofed built mass, (ii) paved courtyards and plazas, (iii) vegetated lawns and gardens, (iv) small water/tank features, and (v) the surrounding urban matrix. These associations are summarised qualitatively below.

Vegetated Lawns and Gardens

The large open lawn occupying the north-central portion of the complex, situated between the entrance gateway and the great hall, is the single most consistent cool feature across all five composites, and forms the coolest zone of the entire site in the Annual, Summer, and Monsoon products. This is the expected thermal signature of a managed turf/garden surface, where evapotranspiration and a comparatively low thermal admittance keep daytime surface temperatures below those of adjacent built and paved surfaces, an effect that is most pronounced when soil moisture is highest, as in the Monsoon composite, and least pronounced under the more uniformly cool conditions of Winter.

Roofed Built Mass and Domed Structures

The principal vaulted hall and the domed rotunda structure to its east register intermediate-to-cool LST in most seasons, appearing in the green-cyan portion of the scale even when adjoining open ground is markedly hotter. This pattern is consistent with the combined effect of high thermal mass, light-coloured lime-plastered masonry, and, for the domed elements, curved geometry that reduces the proportion of surface directly normal to the sun at any one time. The elongated southern building block, by contrast, is consistently among the warmest features of the complex in the Annual, Summer, and Monsoon composites, suggesting a darker or more thermally responsive roofing/paving surface, denser massing, or reduced shading relative to the main hall.

Paved Courtyards and Entrance Plazas

The paved forecourt and entrance plaza at the north-western corner of the complex, where the monument boundary meets the public street, shows a warm signature in the Annual and Post-Monsoon composites in particular, becoming the single warmest zone of the entire site in the Post-Monsoon scene. Hard, impervious paving of this kind typically combines low permeability, negligible evapotranspirative cooling, and comparatively low albedo, producing rapid daytime heating; its prominence specifically in the Post-Monsoon composite is discussed further.

Water and Ancillary Features

Small water and step-well-type features visible within the eastern portion of the complex are not consistently resolved as distinct cool anomalies at the spatial resolution of the thermal grid, which suggests that they are smaller than, or comparable to, a single thermal pixel and their signal is blended with that of the surrounding paved or roofed surfaces. This is a resolution limitation rather than evidence of the absence of a cooling effect.

Surrounding Urban Matrix

Outside the monument boundary, the dense, closely packed residential and bazaar fabric to the west and south-west consistently registers among the warmest surfaces in the wider scene, while the open maidan/park to the north-east of the complex remains comparatively cool. This confirms that the Bada Imambara precinct is embedded within, and thermally buffered relative to, a warmer urban matrix - a configuration characteristic of vegetated heritage enclaves functioning as localised cool islands within denser historic city cores, and one that underscores the value of the complex's internal green space not only for its aesthetic and conservation role but for its microclimatic function within the wider urban fabric.

DISCUSSION

Drivers of Thermal Heterogeneity

Material Thermo-Physical Properties

The Bada Imambara's principal structures are built predominantly of lime-surkhi (brick-lime mortar) masonry finished with lime plaster, with sandstone used selectively for structural and decorative elements. Lime-plastered surfaces typically present a relatively high albedo and moderate thermal admittance compared with modern impervious paving or dark roofing, which is consistent with the comparatively cool-to-intermediate LST recorded over the main hall and dome across most seasons. The contrast between this core structure and the consistently warmer southern block points to a difference in surface finish, roofing material, or paving that would merit ground-truthing, since it cannot be resolved from the thermal imagery alone.

Vegetation and Evapotranspirative Cooling

The pronounced and seasonally responsive cooling of the north-central lawn is best explained by evapotranspiration from turf and tree cover, modulated by soil moisture availability. Its cooling effect is strongest in the Monsoon composite, when soil moisture is at its seasonal maximum, and comparatively muted in Winter, when both vegetation vigor and evaporative demand are lower. This behavior is consistent with the well-established role of urban and heritage green space as a driver of localized surface cooling, and indicates that the lawn functions as an effective thermal buffer at the core of the complex.

Solar Geometry and Shadowing

The most notable spatial reconfiguration in the dataset is the shift of the principal hotspot from the southern built block (Annual, Summer, Monsoon) to the north-western entrance plaza (Post-Monsoon), with Winter showing yet another configuration concentrated along the north-eastern boundary. Because the sun's altitude and azimuth path change substantially between the high-sun Summer/Monsoon months and the low-sun Winter months, the length, direction, and coverage of shadows cast by the complex's tall gateways, minarets, and hall walls change correspondingly. Surfaces that are self-shaded by adjacent structures for much of the day during one season may receive direct, prolonged irradiance in another, which offers a parsimonious explanation for why the same paved plaza is a comparatively minor feature in the Summer composite but the dominant hotspot in Post-Monsoon, and why the eastern wing shifts from an intermediate to the coolest position between the other seasons and Winter.

Seasonal Meteorological Controls

The overall seasonal ordering of absolute LST (Winter < Monsoon < Post-Monsoon < Annual < Summer) follows the expected regional climatology of the Indo-Gangetic Plain, in which Summer is dominated by high insolation and low humidity, Monsoon by cloud cover, rainfall, and elevated soil moisture, and Winter by shorter day length, lower sun angle, and frequent morning fog or haze. The unusually wide intra-scene range recorded in the Monsoon composite (3.86 °C) is plausibly linked to spatially uneven surface wetting and drying immediately following rainfall events, which would differentiate rapidly draining paved/roofed surfaces from moisture-retentive turf and soil far more sharply than under the drier, more thermally homogeneous conditions of Winter, when the narrowest range (1.15 °C) is recorded.

Anthropogenic and Urban-Fabric Influence

The consistently elevated temperatures recorded in the dense urban fabric bordering the complex, set against the comparatively cool open maidan to the north-east, indicate that boundary-adjacent zones of the monument are subject to advective heat influence from the surrounding built environment, in addition to their own surface properties. This is consistent with the general behaviour of heritage precincts embedded in historic urban cores, where the monument's internal green and open spaces provide a measurable thermal contrast with, and potential relief from, the surrounding city.

Implications for Heritage Conservation and Site Management

The thermal patterns documented in this paper carry several implications for the conservation and management of the Bada Imambara complex.

- First, the consistently elevated LST recorded over the southern built block and, seasonally, the north-western entrance plaza identifies these as priority zones for material condition monitoring, since repeated thermal cycling - particularly the sharp diurnal and seasonal swings implied by Summer values approaching 39.5 °C against Winter values as low as 23.85 °C - is a recognized driver of differential expansion and contraction stress in masonry, plaster detachment, and accelerated surface weathering, especially where moisture from Monsoon rainfall is followed by rapid Post-Monsoon and Summer heating.
- Second, the demonstrated cooling function of the north-central lawn underscores the conservation value of maintaining and, where feasible, extending vegetated and permeable surfaces within the complex, both for visitor thermal comfort and as a passive means of moderating the microclimate around adjacent heritage fabric. Conversely, the hard-paved entrance plaza's pronounced Post-Monsoon hotspot suggests that shading interventions - whether through tree planting, seasonal awnings, or permeable paving materials sympathetic to the site's historic character - could meaningfully reduce thermal loading at a high-footfall part of the complex without altering its built heritage.
- Third, the apparent sensitivity of the spatial pattern to solar geometry and seasonal wetting indicates that a single, one-off thermal survey would be insufficient to characterize the site's microclimatic risk profile; the results reported here support the case for continued seasonal monitoring, ideally supplemented by in-situ sensors and higher-resolution thermal imagery capable of resolving individual water features, roofing materials, and shaded microzones that the present satellite-derived products cannot distinguish.

Summary and Limitations

This paper has shown that LST within the Bada Imambara complex varies seasonally over a range of approximately 14–15 °C between Winter and Summer, and that the internal spatial pattern, while broadly stable across the Annual, Summer, and Monsoon composites - with a cool vegetated core and a warm southern built block - reconfigures markedly in the Post-Monsoon and Winter composites, most plausibly in response to changing solar geometry and shadow distribution. Vegetated lawn consistently emerges as the coolest land cover class within the complex, and the dense urban fabric bordering the site as the warmest element of the wider scene, positioning the monument's internal green space as a measurable, seasonally variable thermal buffer. The analysis is nonetheless constrained by its reliance on five rendered thermal composites without an accompanying classified LULC layer, in-situ temperature record, or building-material survey, and by the coarse thermal grid relative to the scale of individual courtyard and water features. The land cover attributions and driver discussion offered here should accordingly be read as a qualitative, image-based interpretation that establishes a set of testable hypothesis - concerning material response, vegetation cooling, shadow geometry, and moisture-driven heterogeneity - rather than as a quantitatively validated causal account.

ACKNOWLEDGEMENT

I sincerely express my gratitude to the Faculty of Architecture & Planning, AKTU, Lucknow for providing the necessary academic support and facilities throughout this research. I am deeply grateful to my guide, Prof. (Dr.)

Indrani Chakraborty, for her valuable guidance, constant encouragement, and constructive suggestions. Her expertise and insightful feedback greatly contributed to the successful completion of this research work.

ABSTRACT

Cahit originally proposed the premise of cordial labelling in 1987. Legendre Cordial Labelling initially emerged by Jason D. Andoyo & F. Rulete in 2025. Inspired by this effort, we introduced Total Legendre Absolute Difference Cordial Labelling.Let $G = (V, E)$,be a connected, a bijection $\varrho: V(G) \to \{1,2,..,|V|\}$ is referred to as a Total Legendre absolute difference cordial labeling modulo ρ (LADCLMρ), with ρ denotes an odd prime, when the induced map $\varrho_\rho^*: E(G) \to \{0,1\}$ characteristic with $\varrho_\rho^*(\mu\nu) = 0$ whence $\left(\delta_{\mu\nu}/\rho\right) = -1$ or $\delta_{\mu\nu} = 0$, also $\varrho_\rho^*(\mu\nu) = 1$ if $\left(\delta_{\mu\nu}/\rho\right) = 1$ or $\delta_{\mu\nu} = 1$, while $|\varrho(\mu) - \varrho(\nu)| \equiv \delta_{\mu\nu}\ (mod\ \rho)$, $0 \le \delta_{\mu\nu} < \rho$, proves the constraints $|e_{\varrho_\rho^*}(0) - e_{\varrho_\rho^*}(1)| \le 1$, whereas $e_{\varrho_\rho^*}(i)$indicates how many edges have been given the identity i $(i = 0,1)$. The induced vertex labeling $g_\rho^*: V(G) \to \{0,1\}$ is defined by $g_\rho^*(v) = 0\ if\ \left(\varrho(v)/\rho\right) = -1\ or\ \varrho(v) = 0\ (mod\ \rho), also\ g_\rho^*(v) = 1\ if\ \left(\varrho(v)/\rho\right) = 1(mod\ \rho)$.

Where $V_{g_\rho^*}(\mathrm{i}) = \{v \in V(G): g_\rho^*(v) = i\}, i = 0,1$.Finally, $\left|\left(V_{g_\rho^*}(0) + e_{\varrho_\rho^*}(0)\right) - \left(V_{g_\rho^*}(1) + e_{\varrho_\rho^*}(1)\right)\right| \le 1$.A Total Legendre absolute difference cordial graph modulo ρ (TLADCGMρ) is a graph that allows such a labelling. The analysis of Legendre absolute difference cordial labelling modulo ρ for certain networks, such aspath P_s, cycle C_s, star S_s, wheel W_s, Gear G_s, is the primary objective of the present investigation.

Keywords: Total legendre absolute difference cordial, star, path, cycle, wheel, Gear graph.
AMS Subject Classification: 05C78, 11A07, 11A15.

INTRODUCTION

Purely finite, fundamental, and connected graphs are accounted for consideration in the present analysis. A plot $G = (V, E)$is made up of an edge set E& a vertex set V, while $|E|$as well as $|V|$stand for the graph's size and order, respectively. In the crucial field of graph labelling, vertices, edges, or both may be given numbers under specific circumstances. It possesses multiple advantages in communication platforms including coding theory. Quadratic congruences resembling $x^2 \equiv \alpha\ (mod\ \rho)$, at which ρ constitutes an odd prime, are of paramount significance in number theory. The Adrien-Marie Legendre symbol $\left(\alpha/\rho\right)$ determines whether the congruence has a solution. If a solution exists, $\left(\alpha/\rho\right) = 1$; otherwise, $\left(\alpha/\rho\right) = -1$. The Legendre symbol is widely used in cryptography, computer science, and engineering [5]. In 1987, I. Cahit [3] introduced cordial labeling, a weaker form of graceful and harmonious labeling. This concept later inspired several new labeling methods, including total product cordial labeling [7]. Lucas divisor cordial labeling [9], and Fibonacci cordial labeling [10]. Some cordial labeling techniques are also applied in areas related to blood circulation and human anatomy [1],[2]. In 2025 Jason D. Andoyo and Ricky F. Rulete [6] introduced Legendre absolute difference cordial labeling motivated by this work, we introduce a new graph labeling method called Total Legendre absolute cordial labeling. By adding the Legendre sign and examining its structure of mathematics as well as practical uses, this innovative, cordial labelling expands on conventional graph labelling.

Preliminaries

Definition:2.1 Graph P_s denote graph assuming the vertices tend to be arranged in the prescribed order$\nu_1,\ \nu_2,\ \nu_3, \dots, \nu_s$and theedge is $\{\nu_i\nu_{i+1}\}$ wherein $i = 1\ to\ s - 1$. Yet a path
is a connected graph containing at least a pair of vertices.

Definition:2.2 A cycleC_s is a graph in which the vertices are arranged in the prescribed order $\nu_1,\ \nu_2,\ \nu_3, \dots, \nu_s$ and the edges are $\nu_i\nu_{i+1}$ where $1 = 1,2, .., s - 1$ together with the edge $\nu_s\nu_1$. In a cycle graph, every vertex has degree 2.

Definition:2.3K_s (complete graph) represent a graph whose vertex is directly connected to all other vertices, with no loops. It hass vertices &s(s−1)/2 edges.

Definition:2.4 A graph developed through joining the points $\nu_1, \nu_2, \dots, \nu_{s-1}$ toward a center vertex $\nu_s$is designated as star graph $S_s$having size n.

Definition:2.5 The **wheel graph**, denoted by $W_n(n \geq 3)$, is the graph obtained by joining a new vertex (called the hub) to every vertex of the cycle C_n.

Definition:2.6 By inserting a vertex across each pair of neighbouring cycle vertices, a gear graph can potentially be built off the wheel. There are 3n edges & 2s+1 vertices in the gear graph G_s.

Definition:2.7 Letting k remain an integer deemed relatively prime with ρ, as well as have ρ represent an odd prime. If there exist a solution to the quadratic congruence $x^2 \equiv k\ (mod\ \rho)$,yields$k$ defines a quadratic residue for ρ. If not, k corresponds to a quadratic nonresidue to ρ. If k constitutes a quadratic residue for ρ, then Legendre symbol (k/ρ) is expressed via $(k/\rho) = 1$; when not, $(k/\rho) = -1$.

Theorem 2.8[8]Considerρas odd prime. Soρ contain $\frac{\rho-1}{2}$ quadratic residues as well as$\frac{\rho-1}{2}$ quadratic nonresidues belong to $\{1,2,3, \dots, \rho - 1\}$.

MAIN RESULTS

Definition:3.1 Let $G = (V, E)$,be a connected, a bijection $\varrho: V(G) \to \{1,2,..,|V|\}$ is referred to as a Total Legendre absolute difference cordial labeling modulo ρ (LADCLMρ), with ρ denotes an odd prime, when the induced map $\varrho_\rho^*: E(G) \to \{0,1\}$ characteristic with $\varrho_\rho^*(\mu\nu) = 0$ whence $\left(\delta_{\mu\nu}/\rho\right) = -1$ or $\delta_{\mu\nu} = 0$, also $\varrho_\rho^*(\mu\nu) = 1$ if $\left(\delta_{\mu\nu}/\rho\right) = 1$ or $\delta_{\mu\nu} = 1$, while $|\varrho(\mu) - \varrho(\nu)| \equiv \delta_{\mu\nu}\ (mod\ \rho)$, $0 \le \delta_{\mu\nu} < \rho$, proves the constraints $|e_{\varrho_\rho^*}(0) - e_{\varrho_\rho^*}(1)| \le 1$, whereas $e_{\varrho_\rho^*}(i)$ indicates how many edges have been given the identity i ($i = 0,1$). The induced vertex labeling $g_\rho^*: V(G) \to \{0,1\}$ is defined by $g_\rho^*(v) = 0\ if\ \left(\varrho(v)/\rho\right) = -1\ or\ \varrho(v) = 0\ (mod\ \rho), also\ g_\rho^*(v) = 1\ if\ \left(\varrho(v)/\rho\right) = 1(mod\ \rho)$. Where $V_{g_\rho^*}(i) = \{v \in V(G): g_\rho^*(v) = i\}, i = 0,1$.Finally, $\left|\left(V_{g_\rho^*}(0) + e_{\varrho_\rho^*}(0)\right) - \left(V_{g_\rho^*}(1) + e_{\varrho_\rho^*}(1)\right)\right| \le 1$.
A Total Legendre absolute difference cordial graph modulo ρ (TLADCGMρ) is a graph that allows such a labelling.

Theorem: 3.2 Path P_ρ admits a Total legendre absolute difference cordial labeling moduloρ.
Proof: Let$V(P_\rho) = \{\alpha_1, \alpha_2, \alpha_3, \dots, \alpha_\rho\}$ and construct a bijective mapping$\varrho: V(P_\rho) \to \{1,2,\dots,\rho\}$ by
$\varrho(\alpha_{2i-1}) = i \qquad \forall\ 1 \le i \le \frac{\rho+1}{2}$,

$$\varrho(\alpha_{2i}) = \rho + 1 - i \quad \forall\ 1 \le i \le \frac{\rho - 1}{2}$$

Then for every edge$\alpha_i\alpha_{i+1} \in E(P_\rho)$,
$|\varrho(\alpha_i) - \varrho(\alpha_{i+1})| \equiv \rho - i\ (mod\ \rho) \quad \forall 1 \le i \le \rho - 1$
Based on this labeling, let $\alpha = \{\delta: |\varrho(\alpha_i) - \varrho(\alpha_{i+1})| \equiv \delta(mod\ \rho), 0 < \delta < \rho, i = 1,2,3,\dots,\rho - 1\}$. So,$\alpha = \{1,2,3,\dots,\rho - 1\}$.By the Theorem2.8,the set α contains an samecount of quadratic residues & quadratic nonresidues modulo ρ, namely $\frac{\rho-1}{2}$of each.Hence $e_{\varrho_\rho^*}(0) = e_{\varrho_\rho^*}(1) = \frac{\rho-1}{2}$. Therefore,$|e_{\varrho_\rho^*}(0) - e_{\varrho_\rho^*}(1)| \le 1$. Now define the vertex labeling $g_\rho^*: V(G) \to \{0,1\}$ defined by

$$g_\rho^*(v) = \begin{cases} 0\ if\ \left(\varrho(v)/\rho\right) = -1\ or\ \varrho(v) = 0\ (mod\ \rho) \\ 1\ if\ \left(\varrho(v)/\rho\right) = 1(mod\ \rho) \end{cases}$$

From this labeling$V_{g_\rho^*}(0) = \rho$ and $V_{g_\rho^*}(1) = \rho$, $e_{\varrho_\rho^*}(0) = e_{\varrho_\rho^*}(1) = \frac{\rho-1}{2}$. Finally, $\left|\left(V_{g_\rho^*}(0) + e_{\varrho_\rho^*}(0)\right) - \left(V_{g_\rho^*}(1) + e_{\varrho_\rho^*}(1)\right)\right| \le 1$. Hence, P_ρ admits a Total legendre absolute difference cordial labeling modulo ρ.

Example 3.3 Figure 1 illustrates the TLADCLMρforP_ρ, with the specific case $\rho = 11$shown as an example.

Corollary: 3.4 Cycle graphC_ρ admits a Total Legendre absolute difference cordial labeling modulo ρprovided that$\rho \le 3$.
Proof: Consider$V(C_\rho) = \{h_1, h_2, h_3, \dots, h_\rho\}$and constructa bijective mapping$\varrho: V(C_\rho) \to \{1,2,\dots,\rho\}$like

$$\varrho(h_{2i-1}) = i \qquad \forall\ 1 \le i \le \frac{\rho+1}{2}$$
$$\varrho(h_{2i}) = \rho + 1 - i \quad \forall\ 1 \le i \le \frac{\rho - 1}{2}$$

Consequently, for $h_ih_{i+1} \in E(C_\rho)$,
$|\varrho(h_i) - \varrho(h_{i+1})| \equiv \{1 \forall\ 1 \le i \le \frac{\rho-1}{2}$

Based on this above labeling suppose that $\alpha = \{\delta: |\varrho(h_i) - \varrho(h_{i+1})| \equiv \delta(mod\ \rho),\ 0 < \delta < \rho, i = 1,2,3,\dots,\rho - 1\}$. In this case by theorem 2.8,the set $\alpha \cup \beta$ contains an equal number of quadratic residues and quadratic nonresidues modulo ρ, namely $\frac{\rho-1}{2}$ of each. Additionally, $\varrho_\rho^*(h_2h_3) = 2$. Therefore, $e_{\varrho_\rho^*}(0) = \frac{\rho-1}{2}$, whereas $e_{\varrho_\rho^*}(1) = \frac{\rho+1}{2}$. Hence $|e_{\varrho_\rho^*}(0) - e_{\varrho_\rho^*}(1)| \le 1$.Now define the vertex labeling $g_\rho^*: V(G) \to \{0,1\}$ defined by

$$g_\rho^*(v) = \begin{cases} 0 \; if \; \left(\varrho(v)/\rho\right) = -1 \; or \; \varrho(v) = 0 \; (mod \; \rho) \\ 1 \; if \; \left(\varrho(v)/\rho\right) = 1 (mod \; \rho) \end{cases}$$

From this labeling $V_{g_\rho^*}(0) = \rho - 1$ and $V_{g_\rho^*}(1) = \rho - 2$, $e_{\varrho_\rho^*}(0) = \frac{\rho+1}{2}, e_{\varrho_\rho^*}(1) = \frac{\rho-1}{2}$. Finally, $\left|\left(V_{g_\rho^*}(0) + e_{\varrho_\rho^*}(0)\right) - \left(V_{g_\rho^*}(1) + e_{\varrho_\rho^*}(1)\right)\right| \leq 1$. Hence, C_ρ admits a Total legendre absolute difference cordial labeling modulo ρ.

Example 3.5 Figure 2 illustrates the TLADCLMρforC_ρ, with the specific case $\rho = 3$shown as an example.

Remark: 3.6 If $\rho > 3$, then the cycle graph $C_\rho$does not admits a Total Legendre absolute difference cordial labeling modulo ρ.

Theorem: 3.7A graph K_ρ admits TLADCGMρ if $\rho \leq 5$.

Proof: Let$V(K_\rho) = \{k_1, k_2, k_3, \dots, k_\rho\}$define a bijective map$\varrho: V(K_\rho) \to \{1,2, \dots, \rho\} \ni \varrho(k_{2i-1}) = i \quad \forall \; 1 \leq i \leq \frac{\rho+1}{2}$, $\varrho(k_{2i}) = \rho + 1 - i \quad \forall \; 1 \leq i \leq \frac{\rho-1}{2}$. Consequently,for $k_i k_{i+1} \in E(C_\rho)$,

$$|\varrho(k_i) - \varrho(k_{i+1})| \equiv \begin{cases} \rho - i \; (mod \; \rho) & \forall 1 \leq i \leq \rho - 1 \\ \frac{\rho-1}{2} \; (mod \; \rho) & \forall i = \rho \end{cases},$$

$|\varrho(k_1) - \varrho(k_{i+2})| = 2i - 1 \quad (mod \; \rho) \quad \forall 1 \; to \; \frac{\rho-1}{2}$,

$|\varrho(k_2) - \varrho(k_{i+3})| \equiv i + 1 \quad (mod \; \rho) \quad \forall 1 \; to \; \frac{\rho-1}{2}$,

$|\varrho(k_3) - \varrho(k_{i+4})| \equiv 1 \quad (mod \; \rho) \quad \forall i = 1,2.$

Based on this above labeling suppose that $\alpha = \{\delta: |\varrho(k_i) - \varrho(k_{i+1})| \equiv \delta(mod \; \rho), \; 0 < \delta < \rho, i = 1,2,3, \dots, \rho - 1\}$ and $\beta = \left\{\delta: |\varrho(k_i) - \varrho(k_{i+1})| \equiv \delta(mod \; \rho), \; 0 < \delta < \rho, i = 1 \; to \; \frac{\rho-1}{2}\right\}$. Thus $\alpha \cup \beta = \{1,2, \dots, \rho - 1\}$. By theorem 2.8,the set $\alpha \cup \beta$contains an same count of quadratic residues & non residues modulo ρ, namely $\frac{\rho-1}{2}$of each. Additionally, $\varrho_\rho^*(k_1 k_\rho) = \frac{\rho-1}{2}$.

Therefore,$e_{\varrho_\rho^*}(0) = e_{\varrho_\rho^*}(1) = 2\left(\frac{\rho-1}{2}\right) + 1 = \rho$

Hence $|e_{\varrho_\rho^*}(0) - e_{\varrho_\rho^*}(1)| \leq 1$.Now define the vertex labeling $g_\rho^*: V(G) \to \{0,1\}$ defined by

$$g_\rho^*(v) = \begin{cases} 0 \; if \; \left(\varrho(v)/\rho\right) = -1 \; or \; \varrho(v) = 0 \; (mod \; \rho) \\ 1 \; if \; \left(\varrho(v)/\rho\right) = 1 (mod \; \rho) \end{cases}$$

From this labeling$V_{g_\rho^*}(0) = \frac{\rho+1}{2}$ and $V_{g_\rho^*}(1) = \frac{\rho-1}{2}$, $e_{\varrho_\rho^*}(0) = e_{\varrho_\rho^*}(1) = \rho$.

$\left|\left(V_{g_\rho^*}(0) + e_{\varrho_\rho^*}(0)\right) - \left(V_{g_\rho^*}(1) + e_{\varrho_\rho^*}(1)\right)\right| \leq 1$. Hence, K_ρ admits a Total legendre absolute difference cordial labeling modulo ρ where $\rho \leq 5$.If $\rho > 5$ then the residue and nonresidue condition is not satisfied. Therefore,Total Legendre absolute difference cordial condition does not hold.

Example 3.8 Figure 3 illustrates the TLADCLMρforK_ρ, with the specific case $\rho = 5$shown as an example.

Remark: 3.9 If $\rho > 5$, then the complete graph $K_\rho$does not admits a Total Legendre absolute difference cordial labeling modulo ρ.

Theorem: 3.10A Star graph S_ρ admits a Total Legendre absolute difference cordial labeling modulo ρ.

Proof: $V(S_\rho) = \{s_0, s_1, s_2, s_3, \dots, s_\rho\}$where s_0 is a central vertex and construct a bijective mapping, $\varrho: V(C_\rho) \to \{1,2, \dots, \rho + 1\}$ by $\varrho(s_1) = 1$ and $\varrho(s_i) = i + 1 \; \forall 1 \leq i \leq \rho - 1$ as an outcome $s_0 s_i \in E(S_\rho), |\varrho(s_0) - \varrho(s_i)| \equiv i \; (mod \; \rho) \; \forall 1 \leq i \leq \rho$. From this labeling, $\alpha = \{\delta: |\varrho(s_0) - \varrho(s_i)| \equiv \delta(mod \; \rho), 0 < \delta < \rho, i = 1,2,3, \dots, \rho - 1\}$ by

Theorem 2.8, the set $\alpha \cup \beta$ contains an equal number of quadratic residues and quadratic nonresidues modulo ρ, namely $\frac{\rho-1}{2}$ of each. Additionally notice that $\varrho_\rho^*(s_0 s_\rho) = 0$. Hence $e_{\varrho_\rho^*}(0) = \frac{\rho+1}{2}$, whereas $e_{\varrho_\rho^*}(1) = \frac{\rho-1}{2}$. Therefore, $|e_{\varrho_\rho^*}(0) - e_{\varrho_\rho^*}(1)| \leq 1$. Now define the vertex labeling $g_\rho^*: V(G) \to \{0,1\}$ defined by

$$g_\rho^*(v) = \begin{cases} 0 \; if \; \left(\varrho(v)/\rho\right) = -1 \; or \; \varrho(v) = 0 \; (mod \; \rho) \\ 1 \; if \; \left(\varrho(v)/\rho\right) = 1 (mod \; \rho) \end{cases}$$

From this labeling $V_{g_\rho^*}(0) = \frac{\rho+1}{2}, V_{g_\rho^*}(1) = \frac{\rho-1}{2}$, and $e_{\varrho_\rho^*}(0) = e_{\varrho_\rho^*}(1) = \rho - 1$.
$\left|\left(V_{g_\rho^*}(0) + e_{\varrho_\rho^*}(0)\right) - \left(V_{g_\rho^*}(1) + e_{\varrho_\rho^*}(1)\right)\right| \leq 1$. Hence, S_ρ admits TLADCGMρ.

Example 3.11 Figure 4 illustrates the TLADCLMρforS_ρ, with the specific case $\rho = 5$shown as an example.

Theorem 3.12 Gear graph G_ρ is a TLADCGMρ.
Proof: $V(G_\rho) = \{g_0, g_1, g_2, \dots, g_{2\rho+1}\}$where g_0 is a central vertex and constructa bijective mapping,$\varrho: V(F_\rho) \to \{1,2, \dots, 2\rho + 1\}$ by
$\varrho(g_0) = \rho$,
$\varrho(g_{2i-1}) = i \;\; \forall 1 \leq i \leq \rho - 1$,
$\varrho(g_{2i}) = 2(\rho + 1) - i \;\; \forall \; 1 \leq i \leq \rho$, $\varrho(g_{2\rho-1}) = \rho + 1$.
As an outcome$g_i g_{i+1} \in E(G_\rho)$,

$$|\varrho(g_i) - \varrho(g_{i+1})| \equiv \begin{cases} 2\rho + 1 - i \; (mod \; \rho) \; \forall 1 \leq i \leq 2\rho - 3 \\ \rho + 1 \; (mod \; \rho) \; \forall i = 2\rho \\ \frac{\rho-1}{2} (mod \; \rho) \; \forall i = 2(\rho - 1) \end{cases}$$

Based on this above labeling$\alpha = \{\delta: |\varrho(g_i) - \varrho(g_{i+1})| \equiv \delta(mod \; \rho), 0 \leq \; \delta < \rho, i = 1,2,3, \dots, \rho - 1\}$. $\beta = \{\delta: |\varrho(g_0) - \varrho(g_i)| \equiv \delta(mod \; \rho), 0 \leq \; \delta < \rho, i = 1,2,3, \dots, \rho - 1\}$. By the theorem 2.10, the set $\alpha \cup \beta$contains same count of quadratic residues & non residues modulo ρ, namely $\frac{\rho-1}{2}$of each. Additionally observe that $\varrho_\rho^*(g_\rho g_1) = 1$ and $\varrho_\rho^*(g_1 g_2) = 0$. Hence $e_{\varrho_\rho^*}(0) = \frac{2\rho-1}{2}, e_{\varrho_\rho^*}(1) = \frac{2\rho+1}{2}$.Therefore,$\left|e_{\varrho_\rho^*}(0) - e_{\varrho_\rho^*}(1)\right| \leq 1$ andnow define the vertex labeling $g_\rho^*: V(G) \to \{0,1\}$ defined by

$$g_\rho^*(v) = \begin{cases} 0 \; if \; \left(\varrho(v)/\rho\right) = -1 \; or \; \varrho(v) = 0 \; (mod \; \rho) \\ 1 \; if \; \left(\varrho(v)/\rho\right) = 1 (mod \; \rho) \end{cases}$$

From this labeling $V_{g_\rho^*}(0) = \rho$ and $V_{g_\rho^*}(1) = \; \rho + 1$, $e_{\varrho_\rho^*}(0) = \frac{2\rho-1}{2} e_{\varrho_\rho^*}(1) = \frac{2\rho+1}{2}$.
$\left|\left(V_{g_\rho^*}(0) + e_{\varrho_\rho^*}(0)\right) - \left(V_{g_\rho^*}(1) + e_{\varrho_\rho^*}(1)\right)\right| \leq 1$. Hence, G_ρ admits a Total legendre absolute difference cordial labeling modulo ρsatisfies the conditions for a LADCLMρ.

Example 3.13 Fig. 5 illustrates the TLADCLM$\rho$for G_ρ, with the specific case $\rho = 5$shown as an example.

Theorem: 3.14 Wheel graph W_ρ, where $\rho \geq 3$admits aTotal Legendre absolute difference cordial graph modulo ρ.
Proof: Take$V(W_\rho) = \{v_0, v_1, v_2, v_3, \dots, v_\rho\}$ and construct a bijective mapping$\varrho: V(W_\rho) \to \{1,2, \dots, \rho + 1\}$ by
$\varrho(v_{2i-1}) = i \qquad \forall \; 1 \leq i \leq \frac{\rho+1}{2}$,

$$\varrho(v_{2i}) = \; \rho - i + 2 \qquad \forall \; 1 \leq i \leq \frac{\rho - 1}{2}$$
$$\varrho(v_0) = \; \rho$$

Then for every edge $v_i v_{i+1}, v_0 v_i \in E(W_\rho)$
$|\varrho(v_i) - \varrho(v_{i+1})| \equiv \rho - j + 1 \;\; (mod \; \rho) \forall 1 \leq i \leq \rho - 1, j = 1 \; to \; p - 1 \; here \; except \; j = 3$

$|\varrho(v_0) - \varrho(v_2)| \equiv 1$

$|\varrho(v_0) - \varrho(v_{2(i+1)})| \equiv i \pmod{\rho} \ \forall 1 \leq i \leq \frac{\rho-3}{2}$

Based on this labeling, let $\alpha = \{\delta: |\varrho(v_i) - \varrho(v_{i+1})| \equiv \delta(mod\ \rho), 0 \leq \delta < \rho, i = 3, \dots, \rho - 1\}$.$\beta = \{\delta: |\varrho(v_0) - \varrho(v_i)| \equiv \delta(mod\ \rho),\ 0 < \delta < \rho, i = 1\ to\ p\}$. Thus $\alpha \cup \beta = \{1,2, \dots, p\}$. By the Theorem 2.9,the set $\alpha \cup \beta$ contains a same count of quadratic residues & quadratic nonresidues modulo ρ, namely $\frac{\rho-1}{2}$ of each. Hence $e_{\varrho_\rho^*}(0) = e_{\varrho_\rho^*}(1) = \frac{\rho-1}{2}$. Therefore, $|e_{\varrho_\rho^*}(0) - e_{\varrho_\rho^*}(1)| \leq 1$. Now define the vertex labeling $g_\rho^*: V(G) \to \{0,1\}$ defined by

$$g_\rho^*(v) = \begin{cases} 0\ if\ \left(\varrho(v)/\rho\right) = -1\ or\ \varrho(v) = 0\ (mod\ \rho) \\ 1\ if\ \left(\varrho(v)/\rho\right) = 1(mod\ \rho) \end{cases}$$

From this labeling $V_{g_\rho^*}(0) = \frac{\rho+1}{2}$and $V_{g_\rho^*}(1) = \frac{\rho+1}{2}$, $e_{\varrho_\rho^*}(0) = e_{\varrho_\rho^*}(1) = \rho$.

$\left|\left(V_{g_\rho^*}(0) + e_{\varrho_\rho^*}(0)\right) - \left(V_{g_\rho^*}(1) + e_{\varrho_\rho^*}(1)\right)\right| \leq 1$. Hence, W_ρ admits a Total legendre absolute difference cordial labeling modulo ρ.

Example 3.15. Fig. 6illustrates the TLADCLM$\rho$for W_ρ, with the specific case $\rho = 5$shown as an example.

CONCLUSION

Presented study introduced TLADCL and established its existence for paths, certain cycles, star graphs, wheel graphs, and gear graphs, while proving its nonexistence for complete graphs with $s > 5$. This work expands the segment of cordial labelling through connecting graph theory together with classical number theory. The long-term prospects research might explore more graph classes and applications in cryptography and related fields.

ACKNOWLEDGEMENT

The authors sincerely thank the Editor and the anonymous reviewers for their valuable comments and suggestions, which helped improve the quality of this manuscript.

ABSTRACT

Low temperature superconductivity of mixed valence rare earth compounds i.e. LuB_{12}, LaB_6, $CeCu_2Si_2$, $CeRu_3Si_2$ etc. has been studied within eight-site model Hamiltonian in the ground state. All calculations, restricted for two electrons, have been done by exact diagonalization method. The effect of pair hopping interaction of *d*-electrons (*J*) in the superconducting mixed valence compounds has been discussed here. *f-d* pair density, *d-d* pair density and effective hopping amplitude have been studied here.

Keywords: Super conductivity, Mixed valence, Rare earth compound, Exact diagonalization method, Pair hopping interaction, Effective hopping amplitude.

INTRODUCTION

A significant number of rare earth compounds exhibits superconducting as well as mixed valence (MV) or fluctuating valence properties [1,2]. The specific heat measurements and point-contact spectroscopy have proved the BCS-type superconductivity in the rare earth compound i.e., lutetium dodecaboride (LuB_{12}) whose transition temperature is near equals to 0.4K [3]. At the beginning of the discovery of this quantum phenomenon, i.e., super conductivity, it was limited to metals and some alloys at extremely low temperature. But a noticeable change has occurred in this conception after the discovery of first high-temperature superconductivity (high-T_c) in 1986. Many cuprate superconductors like La_2CuO_4, $YBa_2Cu_3O_7$etc. and some iron-based superconductors such as $LaOFeP$, $RbEuFe_4As_4$ etc. are the family members of rare earth (RE) compounds. Some RE borides exhibit superconductivity at low temperature. In case of yttrium hexaboride (YB_6), the transition temperature is near around 7.4K and lanthanum hexaboride(LaB_6) is a superconductor with a relatively low transition temperature of 0.45K [4]. Other lanthanum

compounds such as $LaSn_3$, $LaPb_3$ and $LaTl_3$ also show their superconducting nature at 6.45 K, 4.05K and 1.57K respectively [2].

In contrary to the heavy fermion high-temperature superconducting system, the superconductivity, discussed in our present communication, is caused by the *d*-level itinerant electrons and not by the localized *f*-electrons. We would also like to add that the *f*-electrons are responsible for the mixed valence property of rare earth superconductors [5,6]. The ternary *Ce* -rich RE compound, $CeCu_2Si_2$ [6], exhibits superconducting property below 0.6 K. The other MV compound, $CeRu_3Si_2$ shows superconducting nature below 1K, is intermediate between the weak MV systems like $CeSn_3$, $CePd_3$ and strong MV compound like $CeRu_2$. An investigation on the superconducting nature of MVcompounds has been studied within a two-site model Hamiltonian, and some ground state as well as finite temperature properties have also been examined in [7]. The possible coexistence of the superconductivity and MV property has been emphasized with the analytical support of microscopic description [6].By the temperature and magnetic field dependent measurements of electrical resistivity for both normal and superconducting states, at the quantum critical field point, the strange metal behavior of $YbRh_2Si_2$ has been studied in detail [8]. The superconducting property of $CeRu_3Si_2$ [9], $CeRu_2$ and $CeIr_3$[10], has been studied through detailed experimentations under the condition of mixed valence.

A comparable study between phonon superconductivity and Kondo effect in mixed valence and heavy fermion compounds has been presented in [11].Effective interactions such as exchange interaction, interactions associated with Cooper instability and superconductivity with ferromagnetic fluctuations, have been studied within periodic Anderson model under the regime of mixed valence of rare earth compounds [12]. There is no conflict between magnetism and superconductivity, has been shown in case of rare earth borides [1]. The interaction between superconductivity and magnetism of the system of $REFeAsO_{1-x}F_x$(*RE*=Rare earth elements, *x*=doping concentration) has been studied in [13]. At a quantum critical point, the coexistence of superconductivity and anti ferromagnetism of the rare earth intermetallides has been studied in [14-16], particularly in $CeRhIn_5$ [15]. A study on conventional superconductivity with some special as well as contemporary issues like the near-room-temperature superconductivity in LaH_{10} under pressure, high entropy alloy (HEA) superconductivity, creation of nanowires and nanostructures by nanotechnology etc., has been done [17]. The phonon-mediated superconductivity in lanthanum hydride has been studied by the estimation of critical temperature, superconducting energy gap, specific heat and thermodynamic critical field [18]. The experimental evidence on high-temperature superconductivity in hydrides (e.g.,LaH_{10}) under high pressure has been described in [19]. Due to the demand of superconducting technology, many developments on high-temperature superconducting cable [20], superconducting hot electron bolometer (HEB) mixers, used for many astronomical observations on ground, airborne and space telescopes [21], high-temperature superconducting filters, used in wireless communications, space exploration, satellite communications [22] are being continued through ongoing research works.

An extensive study on the MV properties of rare-earth compounds has been carried out in our previous works [23, 24].The present work explores the superconducting properties of rare-earth compounds. The pairing correlations in both the s- and d-wave channels have been examined using Lanczos exact diagonalization on a 4 × 4 cluster, backed by projector quantum Monte Carlo simulations for specific parameter regimes [25]. Here, the findings show that a thorough approach beyond the minimum Hubbard model is necessary for a realistic explanation of unconventional superconductivity and emphasize the critical role of prolonged interactions in forming the pairing landscape of strongly correlated systems. In [26], the effects of an orbital magnetic field on valence transitions and ferroelectric correlations in the two-dimensional spinless Falicov-Kimball model are investigated using a mix of the classical and projector quantum Monte Carlo approach. In our present communication, we focus on the low temperature superconductivity of mixed valence compounds of rare earth elements. Here many interactions associated with superconducting property of mixed valence compounds have been studied within eight-site model Hamiltonian using exact diagonalization method.

Hamiltonian and formulation

The eight-site model Hamiltonian, considered here, is

$$H= -t\sum_{<i,j>\sigma} d^{+}_{i\sigma}d_{i\sigma}+U_{fd}\sum_{i\sigma\sigma'} f^{+}_{i\sigma}f_{i\sigma}\, d^{+}_{i\sigma'},d_{i\sigma'}+U_{dd}\sum_i d^{+}_{i\uparrow}\, d_{i\uparrow}d^{+}_{i\downarrow}d_{i\downarrow}+ J\sum_{<i,j>} d^{+}_{i\uparrow}\, d^{+}_{i\downarrow}d_{j\downarrow}d_{j\uparrow}+ E\sum_{i\sigma} f^{+}_{i\sigma}\, f_{i\sigma} +V\sum_{<i,j>\sigma}(f^{+}_{i\sigma}\, d_{j\sigma}+d^{+}_{j\sigma}f_{i\sigma}) \quad (1)$$

Where, i,j represent all pairs of nearest neighbour sites on a two-dimensional eight sites square lattice;t denotes the hopping interaction of the itinerant d-electrons between nearest neighbour sites, U_{fd} is the on-site Coulomb interaction between the conducting d-electrons and the localized f-electrons, U_{dd} represents the Hubbard type interaction between d-electrons, J is the pair hopping interaction of d-electrons, E denotes the f-level energy, V is the strength of f-d hybridization interaction.σ,σ' represent the spin of both d and f electrons; $d^{+}_{i\sigma}$denotes a creation operator for an itinerant d-electron at site i with spinσ whereas $d_{j\sigma}$denotes an annihilation operator for an itinerant d-electron at site j with spin σ.$f^{+}_{i\sigma}(f_{i\sigma})$ represents a creation (annihilation) operator for a localized f-electron at the site i with spin σ. The representative eight-site spin states are taken in the following form

$$|n^{f}_{1\uparrow}n^{f}_{1\downarrow}n^{d}_{1\uparrow}n^{d}_{1\downarrow}n^{f}_{2\uparrow}n^{f}_{2\downarrow}n^{d}_{2\uparrow}n^{d}_{2\downarrow}n^{f}_{3\uparrow}n^{f}_{3\downarrow}n^{d}_{3\uparrow}n^{d}_{3\downarrow}\dots\dots\dots n^{f}_{8\uparrow}n^{f}_{8\downarrow}n^{d}_{8\uparrow}n^{d}_{8\downarrow}> \quad (2)$$

Here, 488 basis states are generated by our calculation where the ground state is taken in the form

$$|\Psi>=\sum_m C_m\,|\Psi_m> \quad (3)$$

The following formulas are used to obtain the average pair densities for f-d and d-d pairings [27, 28] (for $i \neq j$)

$< n^{f-d} >$=f-d pair density=$<\Psi|\,(f^{+}_{i\uparrow}d^{+}_{i\downarrow}d_{i\downarrow}f_{i\uparrow}+ f^{+}_{i\downarrow}d^{+}_{i\uparrow}d_{i\uparrow}f_{i\downarrow})\,|\Psi>$ (4)

$< n^{d-d} >$ =d-d pair density =$<\Psi|(d^{+}_{i\uparrow}d^{+}_{i\downarrow}d_{i\downarrow}d_{i\uparrow}+d^{+}_{i\uparrow}d^{+}_{j\downarrow}d_{i\downarrow}d_{j\uparrow}+d^{+}_{i\uparrow}d^{+}_{j\downarrow}d_{j\downarrow}d_{i\uparrow}+\ d^{+}_{i\uparrow}d^{+}_{i\downarrow}d_{j\downarrow}d_{j\uparrow}+\ \ d^{+}_{i\uparrow}d^{+}_{j\downarrow}d_{i\downarrow}d_{i\uparrow})|\Psi>$(5)

The effective hopping amplitude is defined as

$$t_{eff}=\frac{\sum_{<i,j>\sigma}<\Psi_0|H|\Psi_0>}{\sum_{<i,j>\sigma}<\phi_0|H|\phi_0>} \quad (6)$$

The ground state wave function of the total Hamiltonian is represented by $|\Psi_0>$ and the ground state wave function of the Hamiltonian without pair hopping interaction J is represented by$|\phi_0>$.

RESULTS AND DISCUSSIONS

In our present communication, we have confined our calculations for 2 electrons. The values of the interaction strengths are taken proportionately. All are measured in eV unit. In Fig.1, initially, most of the electrons are in the f-state and the system is in the insulating phase. However, with the increase of E, the f-electron density decreases with the increase of d-electron density and at a particular E (critical f- level energy) valence transition occurs [29] and the number of d-electrons increases with E. So, the probability of pair formation of the f-and d- electrons is maximum at this value of E where the total number of f- and d- electrons is almost same. But with the increaseof E, the number of d-electron increases decreasing the value of f-electron density. Hence the formation f-d pair density $< n^{f-d} >$decreases and we see that $< n^{f-d} >$ decreases with E after the critical E. At this point of E where a cross-over is observed, the valence transition in the system from metallic to insulating phase occurs. Fig. 2 shows the characteristics of f-d pair density with pair hopping of d- electrons for different hybridisation V. For mixed valence system, valence transition is very sharp when hybridisation interaction is too small (V =0.1). With the increase of V, the transition between f- and d- electrons becomes flat, and the number of f- electrons is almost equal to the number

of *d*-electrons at any site. In figure 2, it appears that $< n^{f-d} >$ increases with *V*. With the increase of *V*, the number of *f*- and *d*-electrons is almost equal, and the probability of formation of *f*-*d* electrons is greater than when *V* is smaller. As a result, $< n^{f-d} >$ increases with *V*. The formation of pair of *f*-electrons with *d*-electrons is facilitated by *d*-electrons pair hopping. Thus, a slight increase in $< n^{f-d} >$ is observed for higher values of *J*. However, for *V*= 0.1, valence transition is sharp [30] which destroys the symmetry between *f*- and *d*- electrons, which reduces $< n^{f-d} >$ for higher *J* values.

With the increase of *J*, *d*-*d* pair density$< n^{d-d} >$decreases at a particular *E*, as showninFig.3. Now, when the interaction *J* is increased, the *d*-electrons with opposite spins move to its neighbouring (*NN*) sites and due to this movement, the formation of *d*-electron pairs at a site decreases. As a result,$< n^{d-d} >$decreases with *J* at a particular *E*. So, we get an increased value $< n^{d-d} >$ at a higher value of *E*[7], the system enters in a fully metallic state. At a particular *E*, the system is fully metallic and no further increase in the number of *d*-electrons happen. Hence $< n^{d-d} >$ saturates at these values of *E*. Fig. 4 depicts the nature of the graphs between the effective hopping amplitude (t_{eff}) and the pair hopping interaction of *d*-electrons *J*. The Hubbard type interaction of *d*-electron (U_{dd}) has been used here as parameter with values 0, 0.5 and 1.0. For the zero value of *J*,t_{eff} goes to 1[31]. With the increase of *J*, t_{eff} decreases from the maximum value of 1. It has also been observed that the decreasing rate of effective hopping amplitude is faster for lower values of U_{dd}. For a particular value of *J*, the increase of U_{dd}movesthe *d*-electrons from one site to another. This in turn, increases the effective hopping amplitude for*d*-electrons.

CONCLUSIONS

In summary, low temperature superconducting properties of MV compounds have been explored using exact diagonalisation method within 8-site square cluster. Hybrid pair ($< n^{f-d} >$) formation attains a maximum when *f*- and *d*-electron numbers are almost same. $< n^{f-d} >$ increases with hybridization interaction *V*. An increased value of *d*-electron pair density $< n^{d-d} >$ is observed at higher values of *E*, but it becomes constant in the fully metallic state. t_{eff} decreases with pair hopping interaction of *d*-electrons *J* as it makes the electrons localized. But, Coulomb repulsion between *d*-electrons increases t_{eff}due to delocalization.

ABSTRACT

One of the most widespread hematological diseases in the world is Iron Deficiency Anemia (IDA) which is a significant issue of public health, especially in developing nations. Early diagnosis and effective management of anemia requires correct identification of the level of anemia and its severity. The conventional diagnosis methodologies employ manual recognition of the hematological values, which might be time-consuming and may not take full advantage of the predictive trends embedded in the clinical information. Machine learning methods in the past years have demonstrated a lot of potential in the field of healthcare data analysis by facilitating automated diseases detection and classification based on parameters. This work aimed to apply binary and multiclass classification, machine learning techniques to predict the impact of iron deficiency anemia based on hematological dataset attributes. The offered methodology will use blood-related parameters to construct predictive models that will help to detect anemia conditions and severity levels. (i) The binary classification method involves classifying samples into two: anemic and non-anemic. (ii) In the multiclass classification, anemia, if detected, is additionally categorized into several levels based on the severity condition of it such as mild, moderate, severe. In order to improve the predictability of the models, the statistical feature selection methods are used to extract the most appropriate attributes that can be used to classify anemia. Machine learning classifiers are then trained and tested using these chosen features in order to develop an effective predictive model. The model performance is measured with the standard values of accuracy, precision, recall, F1-score, and the confusion matrix. The findings indicate that machine learning-based models have

the capability of effectively classifying iron deficiency anemia with high accuracy in healthcare systems. The results indicate the potential of machine learning methods to aid in the early identification and the level of severity of iron deficiency anemia, thus enhancing the effectiveness of diagnosis and patient management.

Keywords: Iron Deficiency Anemia(IDA), Healthcare System, Machine learning, Binary Classification, Multiclass Classification, Hematological parameters.

INTRODUCTION

Recent reports indicate that iron deficiency amenia (IDA) is one of the dominant health challenges facing many populations especially in developing nations where malnutrition and poor access to health prominent. It may cause fatigue, deterioration of thinking ability, weak immune response and severe health problems unless it is diagnosed and treated at an early stage [1]. Anemia diagnosis is usually based on the interpretation of the hematological indicators of regular blood tests. The professionals usually use parameters like Hemoglobin (HGB), Red blood cell count(RBC), Hematocrit (HCT), Mean corpuscular volume(MCV), and Mean corpuscular haemoglobin(MCH) to identify the existence and the severity of anemia[2]. Though the tests are crucial in delivering critical information, the process of interpreting several variables at a go can be complicated and can require a lot of expert knowledge. In addition, traditional diagnostic approaches may not fully utilize the large amount of data generated by modern healthcare systems. The quick evolution of healthcare data and the development of computational technologies have given the possibilities of machine learning (ML) methods in the medical diagnosis. Machine learning algorithms can process big data, detect complex trends and develop predictive models that help in detecting and classifying diseases [3]. ML strategies have been utilized in healthcare analytics to aid in decision-making and enhance diagnostic accuracy in recent years [4] [5]. The techniques allow toperform automated analysis of the data and the methods can greatly optimize the efficiency of the disease prediction systems.

In the context of the diagnosis of anemia, ML techniques can be applied to carry out the binary classification and multiclass classification. Binary classification is concerned with identifying whether a samples is having IDA or not, which is helpful for early screening and preliminary diagnosis. Multiclass classification is a variation of this technique in which the IDA detected patients are divided into various severity levels viz. mild, moderate and severe. This classification allows more information about the progression of the disease and helps to plan the appropriate treatment. ML models are able to successfully identify anemia from hematological datasets with improved prediction accuracy [6]. One of the most significant issues of the data analysis is that, if any high-dimensional features exist, not all the variables play the same role in the prediction. Irrelevant or redundant attributes may diminish the performance of the model and may raise computational complexity. Therefore, feature selection techniques (FST) play an important role in identifying the most informative variables from the datasets. Statistical procedures like Analysis of Variance (ANOVA) and Chi-Square tests have been extensively used to quantify the importance of features and to choose the most important features for classification problems. These techniques can aid in improving the interpretability of the model and in improving the prediction performance.

In this study, a machine learning-based framework is proposed for the binary and multiclass classification of IDA using attributes of hematological data. The model is a combination of the data Preprocessing, feature selection methods as well as classification algorithms to create an effective predictive framework. Feature selection techniques such as ANOVA, F-statistic and Chi-Square tests are used to select the most important blood parameters related to the diagnosis of IDA. Subsequently, Machine learning classifiers such as Logistic Regression and Random Forest are used to develop predictive models which can be utilized to identify iron deficiency anemia conditions and levels of severity. Experimental results show that the machine learning based approaches can effectively detect and classify IDA with the hematological data. It also highlighted the role of machine learning techniques in enhancing the

accuracy of diagnosis and decision making in the analysis of haematological disorders. In general, this research emphasizes the significance of integrating machine learning methodology with healthcare data analytics to develop smart diagnostics. Such systems can help healthcare professionals with early detection and severity categorization of iron deficiency anemia, eventually leading to enhanced patient care and improved management of healthcare.

LITERATURE REVIEW

Garg et al. [7] conducted a survey of the significance of machine learning in medical research with a focus on the role it plays in the analysis of complex healthcare data. The study has emphasized the role of machine learning in early detection, diagnosis and prognosis of diseases by identifying meaningful patterns in clinical data. It discusses supervised and unsupervised methods of learning applied to predict disease, clustering and anomaly detection. The medical imaging, electronic health records and personalized medicine are other applications discussed by the authors. It highlights the importance of feature selection and dimensionality reduction in enhancing model performance. In their study, Joshi et al. [8] overviewed the existing classification-based prediction methods applied in healthcare systems. The researchers have examined different machine learning algorithms including decision trees, support vectors machine and neural networks to predict diseases. It demonstrated strong and weak points of various classification techniques dealing with medical information. The authors have highlighted the need to select features and preprocess data to enhance prediction accuracy. Moreover, the survey also addressed issues such as the imbalance and high dimensionality of healthcare data. Overall, this approach provided valuable insights into the effectiveness of classification techniques for healthcare prediction tasks.

Hammoud et al. [9] suggested a new machine learning architecture to enhance the categorization of intermediate or uncertain instances in healthcare information. The study proposed a systematic workflow that improvements to model decision making, especially of the cases that are not easily categorized. It also highlighted the incorporation of high-level algorithms to enhance the accuracy and reliability of the use in the context of the general health of the people. The findings indicated better classification, particularly with borderline cases. It concludes the importance of specialized architectures in handling complex classification problems. Li et al. [10] proposed a machine learning based approach for anemia prediction using clinical and hematological data. To improve diagnostic accuracy and support clinical decision-making, the study applied multiple classification algorithms for effective disease identification. It also emphasized the importance of preprocessing and feature selection to enhance model performance. The research focused on identifying patterns associated with different anemia conditions using data-driven techniques. The findings demonstrated that machine learning models can serve as efficient tools for early detection of anemia. Additionally, the study highlighted their potential to automate prediction while improving reliability in healthcare applications.

Williams et al. [11] presented an in-depth analysis of methods to enhance anemia assessment across clinical and public health environments. The research implied the enhancement of diagnostic consistency through the inclusion of sophisticated biomarkers and standardized methods of evaluation. It identified the shortcomings of traditional assessment procedures that can cause inappropriate or unreliable findings. The authors emphasized the importance of better reliable, scalable and evidence-based solutions in detecting anemia. Their results emphasized that better diagnosis and treatment outcomes could be facilitated by better assessment strategies. Komninaka et al. [12] suggested a multi classification system of microcytic anemia, comprising of iron deficiency anemia, thalassemia variants and healthy individuals. An investigation has shown that a small number of hematological parameters can be used to classify various types of anemia with high accuracy when applied to machine learning models. Different classifiers were tested to establish their ability to differentiate between related blood disorders. The findings showed that multiclass techniques are much better at enhancing the accuracy of diagnosis than the conventional binary classification techniques. The method has also highlighted the effectiveness of feature reduction in improving model efficiency. This work emphasizes the relevance of multiclass machine learning models to practical settings of hematology diagnostics.

Kamalzadeh et al. [13] proposed a machine learning-based model to identify iron-deficiency anemia based on reticulocyte maturation indices. The research was aimed at using innovative hematological parameters in order to capture slight variations that relate to anemia conditions. It highlighted that integrating AI techniques can enhance the precision of diagnosis compared to conventional laboratory assessments. The authors further highlighted the usefulness of predictive models in helping clinicians in timely and accurate decision-making. They found that their results were better to detect cases of iron-deficiency anemia. On the whole, the study revealed the possibility of AI-assisted hematology to enhance the diagnosis of anemia and clinical workflows. Nurrahman et al. [14] emphasized on multi classification of anemia and iron deficiency through the XG Boost algorithm with employed advanced preprocessing techniques. The research problems, including missing data, class imbalance, and high dimensionality, were addressed through such methods as Miss Forest imputation, Boruta feature selection and SMOTE. These preprocessing techniques were found to have a major impact on the improvement of the classification performance. The study pointed out that effective preprocessing of data is a key factor to the achievement of improved accuracy of multiclass classification. It also illustrated that the ensemble models such as XGBoost are very effective in healthcare classification issues. The research concludes that preprocessing and feature selection are necessary when developing effective anemia classification systems.

Tepakhan et al. [15] developed machine learning models using the random forest and gradient boosting to differentiate between iron deficiency anemia and thalassemia. Though it is more of a classification task, the research is an addition to multiclass frameworks, as it deals with overlapping hematological conditions. The models had a high AUC score and accuracy, which implies that there is a high predictive ability. The study indicates the flaws of the conventional diagnostic formulas and proves the excellence of machine learning methods. It also highlighted the need to employ several algorithms in comparative analysis. The results endorse the application of ensemble learning techniques in the anemia classification. Lv et al. [16] created a machine learning algorithm to differentiate microcytic hypochromic anemia using erythrocyte-related variables. The authors used blood indices to establish typical patterns that are characteristic of certain types of anemia. It highlighted the data-driven models enhance accuracy of diagnostic results compared to conventional analysis approaches. The authors also emphasized the role of the choice of relevant features to improve the performance of the model. Their results suggested that machine learning tools could be successfully used to aid accurate anemia classification. In general, the study revealed the possibilities of automated techniques in enhancing hematological diagnosis.

Kibria et al. [17] presented a fusion method to predict the severity of cardiovascular diseases using machine learning in binary and multiclasses. They used an approach that involves the integration of different models and feature sets to enhance the reliability and robustness of predictions. The combination of various classifiers allowed to more effectively process more complicated clinical data and to achieve better classification results. The experiment established that a combination of several learning strategies could be an effective way of improving prediction effectiveness, particularly in multiclass classification of disease severity tasks.A more sophisticated framework to diagnose multiclass brain tumors through Support Vector Machine (SVM) with novel feature extraction methods was offered by Basthikodi et al. [18]. The aim of the research was to identify discriminative features of medical imaging data in order to enhance the performance of the classification process of various tumor types. Combining effective feature extraction techniques with SVM, the model was found to be very accurate and robust in tumor classification. Their results highlighted that informative features selection is an important factor in increasing the performance of multiclass classification system in the medical imaging application.

Alnaggar et al. [19] created an optimized Gradient Boosting-based model to classify thyroid diseases based on multiclass. The work also used feature optimization to enhance classification of various thyroid disorder types. The model effectiveness was evaluated using various metrics based on accuracy, precision, recall, and F1-score. This approach has shown that the optimized boosting method was much better in predictive accuracy and the computational efficiency, which makes it relevant to real-time clinical decision support systems. The study by Vohra et al. [20] explored the use of multiclass classification algorithms to diagnose anemia among patients in outpatient clinics. The research employed the use of different machine learning models to classify the different forms of anemia

using clinical and hematological data. Assessment of performance based on standard measures revealed that multiclass models were useful in separating between anemia classifications with high accuracy. Their research emphasized the applicability of machine learning methods to real-world clinical settings to efficiently and automatically diagnose anemia. Alshmrani et al. [21] introduced a deep learning-based system to classify lung diseases based on chest X-ray (CXR) images in multi classes. The model used convolutional neural networks to automatically obtain features and categorize various lung conditions. Extensive experiments showed better classification accuracy and strength than the classical methods. The research highlighted the usefulness of deep learning in the processing of complicated medical images and it can be used to help radiologists diagnose correctly and in time.

METHODS AND MATERIALS

Data Acquisition

The dataset used in this research was shared on an open-source platform available from the Kaggle [22] community that contains hematological indicators used in the diagnosis of Iron Deficiency Anemia (IDA). This includes approximately 5201 hematological samples with 30 attributes, which represent the test results of the medical records. It contains a variety of blood parameters which are relevant for anemia diagnosis. These attributes include Hemoglobin (HGB), Hematocrit (HCT), Red Blood Cell count (RBC), Mean Corpuscular Volume (MCV), Mean Corpuscular Hemoglobin (MCH), Mean Corpuscular Hemoglobin Concentration (MCHC), Red Cell Distribution Width (RDW), Platelet count (PLT) and other biochemical features such as Ferritin, Vitamin B12 and Folate, as presented in Table 1.These features offer valuable insights into red blood cell characteristics and iron status, which are necessary to diagnose various forms and severity of anemia. The dataset also includes the categorical attributes such as gender and class-related columns such as Iron_anemia_Class. Furthermore, the patient's health status is classified as Normal, Mild, Moderate and Severe according to the level of anemia in Table2.

Data Preprocessing

Preprocessing is an essential step to ensure the integrity of the dataset to be used in machine learning models. In the current study, the dataset was first checked for inconsistencies like missing values. Null values were used to represent missing values and statistical median valueswas applied to numerical features, which is the preferred method for medical datasets due to its resistance to outliers [23].The dataset originally had several columns for the different levels of anemia, which were merged into one target variable. This allowed for a well-defined classification problem for binary and multi-class classification modeling. The target labels were then encoded to numerical values using label encoding for machine learning. The data was then split into training and testing sets with an 80:20 ratio with a random state set to 6 for consistency. Data normalization was performed for better training of the models through feature scaling. In addition, feature scaling methods like 'Standard Scaler' and 'Min Max Scaler' were used to normalize the data, making it suitable for machine learning algorithms.

The original dataset contained 5201 hematological samples. Initially, the Iron_anemia_Class attribute was used to perform binary classification and distinguish Anemic and Non-Anemic individuals. Based on this screening process, only the 4182 samples identified as Iron Deficiency Anemia were retained for subsequent analysis. These filtered records were then categorized into Normal, Mild, Moderate and Severe classes according to their hemoglobin (HGB) levels for multiclass classification. The distributions obtained during the binary and multiclass classification stages are presented in Tables 3 and 4 respectively. Table 3 presents the distribution of hematological samples after binary classification, showing that 4182 samples were identified as anemic and selected for further severity classification, while 1019 samples were classified as non-anemic. Table 4 presents the distribution of anemia severity levels used in the multiclass classification stage. The number of severe anemia cases is comparatively lower than mild and moderate cases because patients are generally diagnosed and treated during the early stages of anemia, preventing the progression of the disease to severe conditions. This distribution is more complete than the normal distribution and allows the classifiers to learn the distinguishing features of each category for accurate prediction of severity.

Target variable construction

The construction of the target variable is crucial for converting labels in the dataset to a format that can be used by machine learning techniques. In this work, the original dataset had several binary columns indicating the severity of anemia: Normal, Mild, Moderate and Severe. To keep classification consistent, these variables were grouped into one target class by specified logical conditions. This allowed both binary and multiclass classification analysis. Finally, the target variable was converted to a numerical format using label encoding to enable machine learning models to process it. This standardized representation of the target variable maintained consistency, eliminated redundancy and enhanced the performance of classification models.

Machine Learning Models

In the present study, various machine learning algorithms have been employed for binary and multiclass classification of Iron Deficiency Anemia (IDA).The models were chosen according to their classification performance, simplicity and their skills to learn complex relationships between the hematological parameters. Based on the results obtained from the previously published study on feature selection, it was concluded that the two feature selection techniques which were effective namely ANOVA and Chi-Square were used in the proposed hybrid framework. Selected feature subsets were integrated with Random Forest and Logistic Regression classifiers and the performance of both individual and hybrid models were evaluated.

Binary and Multiclass Classification

The research adopts two different classification strategies to give a holistic view of iron deficiency anemia screening and severity classification.

Binary classification

The binary classification approach treats the problem as a two-class classification: anemic and non-anemic. This is most suitable for initial screening and quick decision-making, the goal is to determine if a patient needs to be referred for further investigation. Binary classification is typically efficient and faster, therefore suitable for healthcare scenarios.

Multiclass classification

On the other hand, multiclass classification offers a more comprehensive analysis, dividing patients into four classes: Normal, Mild, Moderate and Severe. This allows for the detection of specific severity levels of anemia, which are essential for diagnosis, treatment and monitoring. Multiclass classification is more challenging due to the need to classify patients into multiple classes, but it provides a more detailed analysis. Multiclass classification can be achieved by using algorithms such as Logistic Regression with a multinomial approach and ensemble methods such as Random Forest. The binary and multiclass models were assessed using performance metrics, enabling a comparison of their efficiency. Combining the two approaches, the present study guarantees the detection of anemia but also its classification into severity levels, thus improving the diagnostic power of the proposed system and aiding the decision-making process.

Random Forest Classifier

Random Forest is a machine learning technique that builds a collection of decision trees and aggregates their predictions to enhance the predictive accuracy and reduce over-fitting. It has proven to be effective in dealing with high-dimensional medical data and capturing complex interactions between features [25].The present work used multiple decision tree estimators of the Random Forest classifier to achieve good prediction performance. It offers feature importance scores, aiding in the selection of the most important hematological parameters for anemia classification. Moreover, Random Forest is robust to noise and can deal with class imbalance in the dataset.

Logistic Regression

Logistic Regression is a popular classification model that is efficient and easy to interpret. The proposed methodology was based on multinomial model, in which binary and multiclass classification was performed. It

predicts class labels by calculating the probability of a given class using a logistic function and selects the class with the highest probability. Logistic Regression is an effective model if there is a linear relationship between the dependent and independent variables [26].The model was trained using scaled features and an adequate number of iterations to ensure stable convergence and improved performance.

Proposed Classifiers: Hemo Nexus-A Hybrid Machine Learning Framework for Iron Deficiency Anemia Severity Classification

To improve classification accuracy, hybrid models were created by integrating feature selection methods with machine learning algorithms. In particular, features were selected using ANOVA and Chi-Square before applying the classifiers. The chosen features were then fed into Random Forest and Logistic Regression classifiers. This combination reduced the dimensionality of the data, removed redundant features and increased the efficiency of the models. Hybrid models were designed to enhance the classification performance by integrating feature selection techniques with machine learning classifiers. In this approach, the dataset was pre-processed using missing value, feature scaling and target label encoding. Then, ANOVA and Chi-Square statistical methods were used to identify the most pertinent features associated with anemia prediction. These techniques were successful in eliminating unnecessary and redundant attributes, and hence enhancing input data quality. Feature subsets optimized in the feature selection step were subsequently used to train the classifiers, namely the Random Forest and the Logistic Regression classifiers. The combination of feature selection and classification algorithms created a hybrid modeling system that was more efficient in terms of computation and simplified the data set. The hybrid models are then implemented for binary and multiclass classification on data of anemia severity. The classifiers were able to be more informative and stable in their learning capabilities by focusing on the most informative features. Standard performance metrics were used to assess the predicted outcomes. Overall, the hybrid methodology demonstrated superior classification results when compared with individual machine learning models. As illustrated in Fig. 1, the hybrid use of statistical feature selection and classification methods substantially enhanced model accuracy and reliability, highlighting the effectiveness of hybrid approaches in medical data analysis and disease prediction.

RESULTS AND DISCUSSION

In this study, binary classification was performed as the initial stage of Iron Deficiency Anemia (IDA) detection. The dataset consisted of 5201 hematological samples**.** The Iron_anemia_Class attribute was used to classify the samples into two categories: Anemicand Non-Anemic. Among the total samples, 4182 samples were classified as Anemic, while the remaining 1019 samples were classified as Non-Anemic. This preliminary screening process enabled the identification of hematological samples indicative of Iron Deficiency Anemia while separating samples without the condition. The binary classification approach simplified the diagnostic process by focusing solely on the presence or absence of anemia without considering its severity. The resulting binary labels were subsequently used to train and evaluate the machine learning models for early anemia detection. The predominance of anemic samples indicates that the dataset primarily consists of hematological samples associated with Iron Deficiency Anemia. The binary classification stage effectively distinguished anemic samples from non-anemic samples, thereby reducing the complexity of the subsequent classification process. This initial screening enabled the machine learning models to focus exclusively on samples classified as Anemic before performing severity classification.

Following the binary classification stage, only the 4182 hematological samples classified as Anemic were retained for multiclass classification. These samples were further categorized into four classes: Normal, Mild, Moderate and Severe based on their hemoglobin (HGB) levels. This classification provided a more comprehensive assessment of Iron Deficiency Anemia by distinguishing different severity levels among the anemic samples. The multiclass classification framework enabled the machine learning models to accurately identify the progression of anemia and support clinical decision-making by assisting healthcare professionals in selecting appropriate treatment strategies according to the severity of the disease. Table 5presents the Comparison of Performance Metrics of Existing and Proposed Classification Models. The performance of the models was assessed based on accuracy, precision, recall, F1

score and sample prediction. Among the feature selection approaches, ANOVA achieved an accuracy of 92%, precision of 91%, recall of 90% and F1-score of 91%, while Chi-Square obtained slightly lower performance with an accuracy of 91% and F1-score of 89%.These results indicate that ANOVA selected more discriminative features for anemia severity classification.

Among the machine learning classifiers, Random Forest achieved superior performance with an accuracy of 92%, precision of 93%, recall of 94% and F1-score of 93%, demonstrating its capability to capture complex relationships among hematological parameters. Logistic Regression achieved comparatively lower performance, with an accuracy of 84% and an F1-score of 86%, indicating limitations in handling the non-linear patterns present in the dataset. The hybrid models significantly improved classification performance by integrating feature selection techniques with machine learning classifiers. Both Chi-Square + Random Forest (ChiForest) and ANOVA + Random Forest (ANORAN) achieved the highest accuracy of 98%, with precision and recall values of 99% and 98%, respectively. These findings demonstrate that combining statistical feature selection with ensemble learning effectively reduces irrelevant features and enhances predictive accuracy. In contrast, the hybrid Logistic Regression models, namely CHILOG and ANOLOG, achieved accuracies of 84% and showed lower predictive performance compared to the Random Forest based hybrids. The Sample Prediction column illustrates the predicted anemia severity for a selected test sample using each classification model. Most models classified the selected sample as Moderate anemia, while the Chi-Square and Random Forest models classified it as Mild anemia.

The proposed hybrid models consistently predicted the sample as Moderate anemia and achieved the highest classification performance, demonstrating their effectiveness and reliability for anemia severity classification. Overall, the experiments demonstrate that the integration of feature selection techniques with Random Forest classifiers considerably improves multiclass anemia severity classification. The superior performance of the ANORAN and ChiForest models highlights the effectiveness of hybrid approaches in accurately identifying Normal, Mild, Moderate and Severe anemia categories, making them suitable for clinical decision-support systems and anemia diagnosis. Fig.2 illustrates the comparative performance of the selected feature selection techniques, machine learning classifiers and hybrid models using accuracy, precision, recall and F1-score metrics. The graph clearly shows that the hybrid models, Chi-Square + Random Forest (ChiForest) and ANOVA + Random Forest (ANORAN), achieved the highest and most balanced performance across all evaluation measures. This demonstrates the effectiveness of integrating statistical feature selection with ensemble learning for IDA classification. Among the classifiers, Random Forest achieved better results than Logistic Regression, indicating its superior ability to capture complex relationships among hematological parameters.

Similarly, ANOVA slightly outperformed, Chi Forest and ANORAN in all performance metrics, suggesting that it selected more discriminative features for classification. Based on the comparative analysis, the CHILOG (Chi-Square + Logistic Regression) and ANOLOG (ANOVA + Logistic Regression) models were excluded from the graphical representation due to their comparatively lower classification performance and to improve the clarity of visualization. Overall, the graph highlights that Random Forest-based hybrid models provide the most accurate, consistent and reliable results for anemia severity prediction, making them the preferred choice for the proposed framework. Fig.3 presents the distribution of sample predictions across the evaluated models. The graph shows that Moderate anemia was the most frequently predicted class, whereas Mild anemia was predicted by only a few models. Logistic Regression, ANOLOG, Chi Forest, ANORAN and CHILOG could classify the sample as 'Moderate', while Chi Square and Random Forest could predict 'Mild'. This is due to the distribution of samples in the dataset as there are many records with Moderate anemia. Consequently, the classifiers were able to learn the characteristics of the Moderate class more effectively. The Random Forest model predicted the selected sample as Mild anemia, while the hybrid models Chi Forest and ANORAN, incorporating feature selection techniques, predicted the same sample as Moderate anemia. This indicates that the selected feature subsets enhanced the model's ability to capture the underlying patterns associated with the Moderate class.

Furthermore, for the selected patient sample, none of the models predicted the Normal or Severe categories, suggesting that the hematological characteristics of the sample were more closely related to the Mild and Moderate anemia classes.The predominance of Moderate predictions demonstrates the stability of the hybrid models and their effectiveness in identifying the appropriate severity level of Iron Deficiency Anemia. Fig.4 presents the confusion matrix of Propose Hybrid classifier (Chi Forest& ANORAN) for multiclass Iron Deficiency Anemia severity classification. The rows represent the actual class labels, while the columns represent the predicted class labels. The diagonal elements indicate correctly classified samples, whereas the off-diagonal elements represent misclassifications. The confusion matrix demonstrates excellent classification performance, with the majority of samples correctly assigned to their respective classes. A total of 315 Mildcases were correctly classified as Mild, 361 Moderate cases were correctly classified as Moderate, 82 Normal cases were correctly classified as Normal and 51 Severe cases were correctly classified as Severe. These results indicate that the Hybrid Random Forest model successfully learned the distinguishing characteristics of each anemia severity level.

However, the confusion matrix contains one misclassified sample, where an actual Severeanemia case was predicted as Moderate anemia. This misclassification is represented by the value 1 in the Severe row and Moderate column. The presence of only a single classification error suggests that the hematological characteristics of this Severe case may share similarities with those of Moderate anemia, leading to a slight overlap between the two classes. Despite this minor misclassification, the model achieved highly accurate predictions across all severity categories. The absence of errors in the Mild, Moderate and Normal classes further demonstrates the robustness of the proposed hybrid approach. The confusion matrix confirms that the Hybrid Random Forest classifier effectively distinguishes between different anemia severity levels and provides reliable predictions for clinical decision-support applications.
Overall, the results indicate that the proposed Hybrid Random Forest model exhibits outstanding classification capability, correctly classifying 809 out of 810 samples, with only one misclassified instance. This corresponds to an approximate classification accuracy of 99.88%, highlighting the effectiveness of integrating feature selection techniques with Random Forest for Iron Deficiency Anemia severity prediction.

An important observation from this study is that, although only anemic samples identified with IDAthrough the Iron_anemia_Class attribute were selected for analysis, a small number of records were categorized as Normal based on their hemoglobin (HGB) levels. This observation suggests that hemoglobin alone is not sufficient for the accurate identification and severity assessment of Iron Deficiency Anemia. Therefore, routine blood investigations should not rely solely on HGB but should also include other hematological parameters such as MCV, Ferritin & RBC. Evaluating these parameters together provides a more comprehensive assessment of iron deficiency and improves the reliability of clinical diagnosis. This finding is consistent with the previously published research papers or studies, including the statistical analysis [27], Support Vector Machine (SVM) [28] and feature selection techniques (FST) [29] based classification models, in which MCV, Ferritin & RBC were consistently identified as the most significant predictors of Iron Deficiency Anemia. The repeated identification of these parameters across different analytical and machine learning approaches demonstrates their robustness and clinical relevance for anemia diagnosis. Therefore, integrating these significant hematological parameters with machine learning models can improve prediction accuracy, enhance severity classification, and support more reliable clinical decision-making for Iron Deficiency Anemia.

CONCLUSION

This study proposed hybrid machine learning framework for the early detection and severity classification of Iron Deficiency Anemia (IDA) using feature selection and machine learning techniques. Initially, binary classification was performed to distinguish anemic and non-anemic samples. Subsequently, the samples classified as anemic were further analyzed through multiclass classification to identify Normal, Mild, Moderate, and Severe anemia based on hemoglobin (HGB) levels. The proposed hybrid models, ANORAN and Chi Forest, provided more accurate and reliable anemia severity classification than the individual machine learning models by effectively combining feature

selection and classification techniques. The proposed framework effectively classified Iron Deficiency Anemia severity with high accuracy and reliability, highlighting its potential to assist healthcare professionals in the early detection and severity assessment of anemia. The findings have also shown that the use of hemoglobin alone is not enough to diagnose IDA and therefore, other hematological parameters such as MCV, Ferritin and RBC should be evaluated in conjunction to get a more accurate IDA diagnosis. This observation is consistent with the previous statistical analysis, SVM and feature selection studies, where these parameters were repeatedly identified as the most significant predictors of Iron Deficiency Anemia. Thus, the suggested proposed system is a reliable and applicable decision support system for anaemia screening and severity prediction.

ABSTRACT

This study examines the perceived economic and practical viability of household rooftop solar photovoltaic (PV) systems in Thiruvarur District, Tamil Nadu. The analysis is based on primary data collected from 180 households located in Nannilam, Kudavasal and Koradachery blocks, supplemented by secondary information. A structured questionnaire was administered using a convenience sampling technique, and the data were analysed primarily through descriptive statistics and a chi-square test. The findings indicate relatively high awareness of rooftop solar technology: 64.48% of respondents reported a high level of awareness. The installed-capacity profile is concentrated in medium and higher-capacity systems, with 45.90% reporting 3 kW systems and 22.40% reporting systems above 3 kW. Economic perceptions are also favourable, with 62.30% considering rooftop solar highly cost-effective. Further, 78.69% reported that solar generation was either adequate or more than adequate for household requirements. Satisfaction is high, with 50.82% highly satisfied and 40.98% satisfied. Nevertheless, the perceived payback period remains a significant consideration: 66.67% reported a period of 6–10 years and 18.58% reported more than 10 years. The chi-square analysis (χ^2 = 1.19; 6 d.f.; 5% critical value = 12.592) indicates no statistically significant association between household income and perceived cost-effectiveness. Overall, the evidence suggests that rooftop solar is viewed as a viable long-term household energy investment, while financing, awareness, technical support and simplified policy implementation remain important for wider adoption.

Keywords: Renewable energy; rooftop solar PV; household energy; cost–benefit analysis; payback period; Thiruvarur; Tamil Nadu.

INTRODUCTION

Energy availability is fundamental to household welfare and economic development. Rising electricity demand associated with population growth, changing lifestyles, technological development and expanding economic activity has increased the importance of reliable and sustainable energy sources. Solar energy provides a renewable alternative to fossil-fuel-based electricity because photovoltaic systems convert solar radiation into electricity without direct fuel combustion. The economic relevance of rooftop solar at the household level arises from its potential to reduce grid electricity purchases and provide long-term energy savings. India has promoted solar energy through national and state-level programmes. The uploaded study notes the role of the Jawaharlal Nehru National Solar Mission and Tamil Nadu's policy initiatives, including support for residential grid-connected photovoltaic systems and net-metering arrangements. These measures are intended to reduce adoption barriers and encourage decentralised renewable-energy generation. Within this policy environment, household rooftop solar has become relevant not only as an environmental intervention but also as a household investment decision. Thiruvarur District provides a useful setting for examining household solar utilization because the study area includes households with substantial electricity consumption and a relatively favourable capacity to invest in rooftop systems. The empirical issue is therefore not simply whether solar technology is technically available, but whether households perceive the investment as economically worthwhile after considering installation expenditure, maintenance requirements, electricity savings, system capacity and the time required recovering the initial investment.

Household Rooftop Solar Energy: Analytical Context

Household adoption of rooftop solar can be understood as an investment decision under uncertainty. The initial capital cost is incurred at installation, while economic benefits accrue over the operating life of the system through reduced electricity expenditure and, where applicable, the treatment of surplus generation under the prevailing grid arrangement. Consequently, the economic attractiveness of a system depends on the relationship between initial investment, annual savings and the expected payback period. The study also considers non-financial benefits. Solar electricity can reduce dependence on conventional grid electricity and contribute to lower reliance on fossil-fuel-based generation. From a household perspective, perceived energy security and environmental benefits may complement monetary savings. However, adoption may be constrained by upfront expenditure, incomplete knowledge of subsidies, technical uncertainty and concerns about maintenance and system performance.

REVIEW OF SELECTED LITERATURE

Statement of the Problem

Although rooftop solar can provide long-term electricity savings, household adoption is influenced by the size of the initial investment, awareness of financial incentives, expected system performance, maintenance requirements and the time required to recover the investment. The study area also requires district-level empirical evidence on household perceptions of cost-effectiveness and practical utilization. The present study addresses this gap by examining the socio-economic characteristics of sampled households, perceptions of rooftop solar benefits and costs, perceived payback periods and the relationship between household income and perceived cost-effectiveness.

Objectives of the Study

- To Analyse the socio-economic characteristics of the sample households.
- To evaluate household perceptions of the cost and benefits of rooftop solar energy adoption.
- To examine the perceived payback period associated with rooftop solar investment.
- To provide policy recommendations for improving household solar-energy utilization.

METHODOLOGY

The study uses both primary and secondary information. Primary data were collected through a structured questionnaire from 180 households in Nannilam, Kudavasal and Koradachery blocks of Thiruvarur District. Convenience sampling was used. The analysis is predominantly descriptive, presenting frequencies and percentages for socio-economic characteristics and household perceptions. A chi-square test was additionally employed to examine the association between family monthly income and perceived cost-effectiveness of solar boards.The empirical interpretation is based on respondents' reported perceptions rather than an engineering simulation of system output or a discounted cash-flow model. Accordingly, terms such as cost-effectiveness, adequacy of generation and payback period refer to the perceptions reported by the surveyed households. This distinction is important when interpreting the findings.

RESULTS AND DISCUSSION

The sample is concentrated in the economically active age groups. Respondents aged 31–45 years constitute 30.05%, followed by those aged 46–60 years (26.23%). Male respondents account for 69.40%. Households with more than five members represent 41.53%, indicating a relatively large household structure. The occupational distribution is led by own business (34.42%), followed by private employment (27.87%) and government employment (20.77%). The income distribution is comparatively concentrated in the ₹1,00,001–₹2,00,000 category (31.15%). Individual houses constitute 44.26% of the sample, and 61.75% of households report electricity consumption above 1,000 units. These characteristics indicate substantial household electricity demand and physical conditions that can support rooftop installation. Awareness is relatively high: 64.48% of respondents report a high level of awareness, compared with 24.04% at the medium level and 11.48% at the low level. The result indicates that information about rooftop solar has reached a substantial share of the sampled households. Nevertheless, the medium- and low-awareness groups indicate continuing information requirements concerning system selection, installation, financial support and long-term economic benefits

The installed-capacity distribution is concentrated around 3 kW systems. A total of 45.90% report 3 kW systems, while 22.40% report systems above 3 kW. The predominance of medium- and higher-capacity installations is consistent with the relatively high electricity consumption reported by the sample. The 1 kW category accounts for only 11.48%, suggesting that smaller systems are less common among these households. A majority of respondents (62.30%) perceive rooftop solar as highly cost-effective, while 26.22% classify it as moderately effective and 11.48% as less effective. The result suggests broad recognition of the economic advantages of rooftop solar. However, the reported perceptions should not be interpreted as a direct estimate of financial return because the survey does not provide a household-level discounted cash-flow calculation. The majority of respondents report adequate solar generation. Specifically, 42.62% consider generation sufficient and 36.07% consider it more than sufficient; together these categories represent 78.69% of respondents. A smaller group (21.31%) reports inadequate generation. Differences in household load, installed capacity, system performance and solar availability may contribute to these perceptions, although the present survey does not statistically isolate these effects.

The survey records a favourable perception of rooftop solar relative to traditional energy sources. The combined share reporting more or medium benefits is 77.70%. Respondents may associate these benefits with lower electricity expenditure, renewable-energy characteristics, energy independence and available incentives. The remaining responses indicate that some households continue to perceive limitations in economic or operational performance. Satisfaction is high in the sample. More than half of the respondents (50.82%) are highly satisfied and a further 40.98% are satisfied. Only 8.20% report dissatisfaction. The source article attributes dissatisfaction primarily to situations in which solar generation is insufficient to match household electricity consumption. Maintenance expenditure is predominantly perceived as moderate. Half of the respondents (50.27%) classify maintenance costs as

medium, while 28.96% perceive them as high and 20.77% as low. The finding suggests that maintenance is a relevant economic consideration, even though it is not uniformly perceived as a major barrier. The perceived payback period is predominantly 6–10 years (66.67%). A further 18.58% report a period above 10 years, whereas 14.75% expect recovery within five years. This distribution indicates that households generally regard rooftop solar as a medium- to long-term investment. The relatively long perceived recovery period can affect adoption decisions, particularly where households face capital constraints.

Chi-square Test of Association

The study tests the association between family monthly income and perceived cost-effectiveness of solar boards. The reported null hypothesis is that there is a significant association between income and perceived cost-effectiveness. The reported chi-square statistic is $\chi^2 = 1.19$ with 6 degrees of freedom. The critical value at the 5% significance level is 12.592. Since $1.19 < 12.592$, the null hypothesis as stated in the source is accepted. Thus, the study reports no statistically significant association between family monthly income and perceived cost-effectiveness. The descriptive pattern also shows that high cost-effectiveness is reported across all income categories, suggesting broadly favourable perceptions across the sampled income groups.

Key Findings

- 64.48% of respondents report a high level of awareness of rooftop solar technology.
- 45.90% of households have installed 3 kW systems, and 22.40% have systems above 3 kW.
- 62.30% perceive rooftop solar as highly cost-effective.
- 78.69% report that solar generation is either enough or more than enough for household requirements.
- 77.70% perceive rooftop solar as providing more or medium benefits relative to conventional energy.
- 91.80% of respondents are either satisfied or highly satisfied with rooftop solar.
- 50.27% perceive maintenance costs as medium.
- 66.67% perceive a payback period of 6–10 years.

The reported chi-square result shows no significant association between income and perceived cost-effectiveness.

Policy Implications

The empirical evidence points to several policy priorities. First, financial mechanisms should reduce the burden of upfront investment through transparent subsidies, accessible low-interest finance and clearly communicated incentive structures. Second, administrative procedures for residential rooftop systems should be simplified and standardized to reduce transaction costs. Third, technical support should cover system sizing, installation, maintenance and post-installation service. Fourth, awareness programmes should move beyond general promotion and provide households with practical information on system capacity, expected generation, financial incentives and payback. Fifth, community or shared-solar arrangements may provide an alternative for households that cannot install adequate systems on their own rooftops. Finally, systematic monitoring and evaluation are necessary to assess whether policy support translates into sustained household-level utilization.

CONCLUSION

The study provides empirical evidence of favourable household perceptions of rooftop solar energy in the selected blocks of Thiruvarur District. The sampled households demonstrate relatively high awareness, substantial use of medium- and high-capacity systems, positive perceptions of cost-effectiveness and high satisfaction with solar electricity. At the same time, the perceived payback period of 6–10 years for most respondents indicates that the economic case is viewed primarily from a long-term investment perspective. Maintenance costs and inadequate generation for a minority of households remain practical concerns. The reported chi-square result does not identify a statistically significant relationship between household income and perceived cost-effectiveness. This suggests that positive perceptions are not confined to a single income category within the sample. Overall, rooftop solar is perceived as an economically and environmentally relevant household energy option. Wider adoption, however,

depends on accessible finance, effective incentives, reliable technical support, streamlined procedures and targeted awareness programmes.

Recommendations

- Strengthen and simplify subsidy, tax-benefit and low-interest financing mechanisms.
- Streamline approval, connection and installation procedures for residential rooftop systems.
- Improve technical training, after-sales service and maintenance support.
- Provide transparent information on system capacity, expected generation, incentives and payback.
- Promote community solar options for households with inadequate rooftop space.
- Establish regular monitoring and evaluation of household solar programmes.
- Encourage coordination among government agencies, industry and educational institutions.
- Integrate household rooftop solar into long-term district and state sustainable-energy planning.

ABSTRACT

Fog computing technology has become an important computing technology by reducing latencies, optimizing resources, and offering security for real-time IoT systems. An analysis of 25 articles has been conducted to investigate the recent developments in fog computing technology between 2023 and 2026. The selected literature has been classified into resource management and task scheduling, security and trust management, intelligent threat detection, federated defense, architecture, interoperability, and IoT applications. Important methods adopted in the selected literature include machine learning, deep learning, reinforcement learning, fuzzy logic, blockchain, zero trust security, federated learning, simulated annealing, particle swarm optimization, and multi-agent deep reinforcement learning. It can be seen that most of the current fog computing researches are about task offloading, energy optimization, intrusion detection, healthcare security, Industrial IoT, smart farming, smart grids, vehicular networks, and smart city applications. Some important issues in fog computing are scalability, computational cost, communication overhead, heterogeneous deployment, privacy preservation, and real-time adaptability. Finally, this survey shows that AI-based fog computing has improved resource optimization and security of real-time IoT systems.

Keywords: Artificial Intelligence, Fog Computing, Internet of Things, Resource Management, Security, Task Scheduling

INTRODUCTION

A new concept in distributed computing, termed fog computing, has emerged where the computations and the data are provided near the end users and IoT devices. It leads to reduced latency and efficient bandwidth utilization and decision-making in constrained resources. The use of artificial intelligence-based techniques for fog computing resource management and other related topics have been described in [1]. The investigation of reinforcement learning and deep learning-based offloading techniques for improved task execution and resource management in the fog computing domain has been illustrated in [2]. In [4], dynamic task allocation by means of improved fuzzy logic for uncertain environment in fog computing has been discussed. Hybrid intelligence in conjunction with optimization scheduling algorithm in fog computing has recently received attention from researchers. The concept of hybrid task scheduling in fog computing using fuzzy logic and deep reinforcement learning has been introduced in [5]. Quantile temporal difference learning in tiny language models for improved application placement in the Internet of Things has been presented in [6]. Small language models for flow Q-Learning in fog computing tasks scheduling have been developed in [7].Machine learning-based applications for quality-of-experience aware improvement in resource utilization efficiency have been deployed in [8]. In [9], Lyapunov-based LSTM particle swarm optimization approach has been utilized to minimize energy consumption in Internet of Things fog computing. Simulated annealing-based priority aware multi-objective task scheduling approach has been proposed in [10]. Multi-agent twin delayed deep deterministic policy gradient approach for delay aware task offloading and resource allocation has been designed in [11].

One more characteristic of fog computing, which is important for its functioning, is security, privacy, and trust management as the sensitive data processing takes place near the edge devices and fog nodes. The comprehensive analysis of the security, availability, and reliability problems in fog computing was offered in [12]. The zero-trust and blockchain security system for fog computing in the healthcare domain was proposed in [13]. A robust fog computing system based on machine learning for healthcare applications was developed in [14]. Fog computing security in the industrial IoT domain, which covered such aspects as secure computing, offloading, and trust management, was presented in [15]. Therefore, these works prove that fog computing has been evolving not only in terms of the resource management problem but also in intelligent offloading, healthcare security, industrial IoT security, and IoT applications.

Background Study

Almuseelem (2025) [16] to ensure safe task offloading in Internet of Medical Things application using federated learning and zero-trust security. Improvement in the area of secure offloading, privacy, and latency dependent task offloading in a dynamic IoMT environment were highlighted in this research. The optimization in the process of secure offloading was achieved, but further enhancement of adaptability to resource-limited and heterogeneous edge environments was still required. Hameed and Kurnaz (2024) [17] A reliable forwarding approach was introduced by for IoT applications using fog computing. This method uses MQTT communication, fog nodes, trust evaluation, authentication, secure communication, and integrity check to forward data reliably. In the experiment conducted, 15 fog nodes were used and the maximum level of trust of 0.968 and prediction accuracy of high was obtained. But there is no significant number of fog nodes used in the experiment. Lee et al. (2025) [18] proposed a secure and effective authentication scheme for fog based vehicular ad-hoc network. This scheme consisted of lightweight authentication between the vehicle users, fog nodes, and cloud servers in order to ensure secure communication in VANET. The proposed scheme resulted in computation time of 12.023 ms, whereas dense vehicular mobility and scalability were yet to be investigated.

Alamri et al. (2026) [19] proposed energy efficient threat detection framework for IoT healthcare using AI and blockchain based fog-cloud computing architecture. This framework used techniques such as artificial intelligence, blockchain security, and fog-cloud computing for secure processing of health care data and threat detection. The proposed architecture was able to create blocks in less than 20 ms, where AUC = 1; but, there were challenges with

blockchain overhead and lightweight deployment on health care devices. Al-Sharafi et al. (2025) [20] proposed a federated learning based zero trust framework for detecting attacks on IoT consumers. The suggested solution succeeded in improving the detection of attacks through the use of distributed learning and zero trust approach without putting users' privacy at risk. Still, communication overhead, convergence time, and scalability remained relevant problems in this framework.

Almuseelem (2025) [16] created a secure latency aware task offloading approach for Internet of Medical Things using federated learning and zero trust. In this approach, security of the offloading process, user privacy protection, and latency sensitive tasks handling have been taken into consideration. This framework improved the secure offloading but required further research to make it applicable for devices with limited resources. Hameed and Kurnaz (2024) [17]Forwarding Scheme in Fog Computing IoT Systems.This scheme consists of the following components: MQTT communication protocol, fog nodes, trust evaluation, authentication, reliable communication approaches, and data integrity checking. In the simulation with 15 fog nodes, the highest Level of Trust was achieved equal to 0.968 with an accuracy of high but large-scale tests of fog nodes were necessary. Lee et al. (2025) [18] is Efficient Authentication Scheme for Fog Computing-Based VANETs .The proposed authentication scheme was implemented between the users of vehicles, fog nodes, and cloud servers in order to improve secure communications in VANET. The total computation time of the authentication scheme is 12.023 ms, however, further researches are necessary because of dense vehicular mobility.

Alamri et al. (2026) [19] is the threat detection framework for IoT healthcare by was energy efficient as a result of adopting the fog-cloud architecture along with AI and blockchain technology. This framework incorporated artificial intelligence, blockchain, and fog-cloud computing in order to guarantee secure computation and threat detection. The framework was able to produce block generation time below 20 ms and AUC = 1 but blockchain overhead was the challenging part. Al-Sharafi et al. (2025) [20] is the zero-trust attack detection model by was developed under the Consumer Internet of Things Security domain with the help of federated learning. The attack detection technique took advantage of the concept of distributed learning and zero trust. But the major problems with this model were communication overhead and convergence delay. Table 1 is the presentation of the summary of latest researches concerning fog computing, secure task offloading, intrusion detection, healthcare monitoring and smart city application using AI. The comparison of all works has been done in terms of concepts, methodologies, limitations and results for identifying gaps in researches and ways for improvement.

Research Gap

All the above-mentioned researches have applied the use of such approaches as block chain, machine learning, federated learning and artificial intelligence to solve problems related to the issues of security, privacy, task optimization and intelligent algorithm implementation in case of fog computing. However, it should be pointed out that currently, there are still some challenges in relation to the creation of an effective and adaptive framework for dynamic fog computing environment.

The Latest Researches in Fog Computing: Resource Management, Security, and IoT Solutions

In the current chapter, we can see the latest achievements in the area of fog computing, which cover such topics as smart resource management, communication security, and application areas in IoT systems. There are some techniques of AI, ML, optimization and others used to increase the performance of fog.

Resource Management and Scheduling in Fog Computing with AI

Resource management in fog computing based on AI technologies was researched to identify trends, challenges [1]. The survey looked into the ways of usage of AI methods to solve the problems of task allocation, resource optimization, latency reduction and services management. The result proved that AI helped to manage fog resources, but the problem of scalability, energy consumption, and optimization still needed to be solved. Off loading mechanisms in fog computing were researched by using the techniques of reinforcement learning and deep learning[2]. The focus of the survey was put on intelligent offloading decision-making, resource allocation, and

latency-aware task processing. The survey proved that RL and DL enhanced offloading processes but had some limitations. In this study, task scheduling in fog computing systems was analyzed using deep learning [3]. Here, the technique utilized learning-based scheduling to enhance task placement, resource utilization, and task execution. The outcome yielded efficient scheduling capabilities, but heterogeneous fog resources and varying workloads needed further research.

In this study [4], task allocation in fog computing was proposed using improved fuzzy logic. The technique addressed uncertainty in task allocation and provided a flexible decision-making environment for fog resource management. The outcome produced effective task allocation capabilities, but large-scale real-time validation was needed. In this study [5], hybrid task scheduling in fog computing was analyzed using fuzzy logic and deep reinforcement learning. The technique involved the combination of fuzzy decision-making and DRL learning to enhance task scheduling. The outcome yielded efficient task scheduling capability, but computational overhead and dynamic workload needed further research. Fog computing for IoT application placement using quantile temporal difference learning with tiny language models was proposed [6]. The placement decision process was made intelligent by using language-model and reinforcement learning techniques. This approach produced successful results in terms of IoT application placement; however, scalability and deployment in fog computing environments were left to be considered in the future. Optimal task scheduling in fog computing was analyzed by proposing tiny language models along with flow Q-learning approach [7]. The technique made use of lightweight language models along with Q-learning to make smart scheduling decisions. Successful results were obtained from this technique; however, implementation under limited resources and real-time validation were still future tasks to be considered. Application deployment in fog computing considering quality-of-experience requirement was done through machine learning[8]. The technique utilized adaptive application deployment to optimize application placement, resource allocation, and QoE requirements. The result achieved a bandwidth utilization of 5.2% improvement, scalability of 3.2%, energy efficiency of 3.8%, response time of 2.1%, and maintained the prediction accuracy at +0.4%.

Optimal energy consumption in IoT fog computing was analyzed through Lyapunov-Based LSTM Particle Swarm Optimization[9]. The model optimized scheduling tasks and queuing stability based on various latency requirements. As a result, the model saved 9.44% of energy consumption compared with LPSO and 32.73% compared with the Greedy algorithm. Multi-objective task scheduling in fog computing based on priority was suggested through Simulated Annealing[10]. The model performed analysis between SA and ACO, PSO, I-FASC, and M2MPA on small, medium, and large task datasets. The results showed reliability values of up to 0.9849 for small data, 0.9896 for medium data, and 0.9889 for large data. Delay sensitive task offloading and resource allocation in fog computing was analyzed using multi-agent deep reinforcement learning approach[11]. The model adopted MAFCPTORA with Multi-Agent Twin Delayed Deep Deterministic Policy Gradient for cooperative offloading and resource allocation. As a result, the following outcomes were achieved: average reward = 0.36 ± 0.01, average latency = 0.08 ± 0.01, and energy consumption = 0.76 ± 0.14. Table 2 summarized the fog computing based machine learning approaches utilized for task allocation, QoE aware deployment, healthcare security, zero trust detection, and smart grid intrusion detection. The table demonstrated how ML helped in decision making, prediction, and improvement in security. Some researches gave exact results, while others only offered theoretical/qualitative performance improvements Table 3 shows the comparison of deep learning based approaches that have been used in offloading, task scheduling, intrusion detection, smart farming, and smart city monitoring applications. It demonstrates the use of DL algorithms like DRL, CNN, YOLOv8, and object detection in enhancing decision making and automation in fog computing. Specific metrics are provided wherever possible.

Security, Privacy, and Trust Management in Fog Computing

Security, availability, and reliability in fog computing were investigated using the holistic security technique[12]. This technique ensured protection of the fog environment from potential security threats and increase the availability and reliability of the services. The result revealed improved security consciousness, though no numerical values are available from the provided notes. Zero-trust fog healthcare security based on the use of blockchain technology was proposed[13]. The technique utilized the processes of authentication, trust management, and intrusion detection in

order to protect the healthcare information stored in fog computing. The result led to a 40% increase in intrusion detection and a 39.66% reduction in response time. Secure fog healthcare was proposed with machine learning and blockchain technologies [14]. The objective of this technique is increasing privacy, data integrity, and secure healthcare data processing in fog computing. The result revealed high prediction accuracy with low computational and communication overhead, although practical realization requires additional research. Trust-based secure computing in fog-enabled Industrial Internet of Things was explored for task execution and task off loading[15]. This technique used trust evaluation to improve legitimate task execution and secure fog computing in industrial processing. The outcome was the improvement of legitimate task execution, reduction of processing time, and improvement of trust evaluation.

Secure latency-aware task offloading for Internet of Medical Things was suggested using federated learning and zero-trust security [16]. This technique helped improve secure edge computing because it enabled privacy-preserving and latency-sensitive offloading. However, the adaptability of the proposed technique to resource-constrained IoMT devices needed further exploration. Data forwarding in IoT via fog computing was suggested using the MQTT-based forwarding technique [17]. This technique used fog nodes, trust evaluation, authentication, secure communication protocols, and data integrity verification. The technique used 15 fog nodes and the outcome was LoT = 0.968 with high accuracy. Authentication process of secure fog-based vehicular ad hoc networks was explored [18]. The process involves the use of a light weight authentication process between vehicle users, fog nodes and cloud servers. This gave the total computation time of 12.03 ms This figure 1, demonstrates the three-tier model of fog computing, which consists of three layers. At the bottom layer are the IoT nodes, which produce real-time data, while at the second layer are the fog servers that carry out local processing and communicate. On the other hand, the cloud server forms the top tier and offers services such as data storage and complex analytics. The arrows demonstrate the two-way data flow among the IoT nodes, fog servers, and the cloud.

Intelligent Threat Detection and Federated Defense in Fog-Enabled Systems

Energy-efficient threat detection in IoT healthcare was presented through an AI and blockchain-based fog-cloud system [19]. This approach combines AI, blockchain security and fog-cloud computing to provide secure healthcare threat detection. As a result, the approach managed to reach block creation time less than 20 ms and AUC=1 along with high F1-score and high accuracy. Zero trust attack detection in Consumer IoT was presented through federated learning [20]. This approach leverages EGTO-FLADC to enable privacy preserving distributed attack detection. The result is very efficient, but the communication overhead, convergence, and scalability still pose major challenges. Real-time zero trust attack detection in 5G edge network was investigated through machine learning [21]. In particular, the KNN and SVM models were applied in SDN enabled 5G edge environment to detect the malicious activities. The result provided high accuracy and F1-score, but no exact figures were provided in the provided notes.
Approaches of federated learning for intrusion detection in IoT have been systemically studied [22]. The method studied the privacy-preserving distributed learning approaches for detecting IoT attacks. The result proved that federated learning allowed performing secure intrusion detection; however, no specific numeric values were provided in the available notes.

Collaborative machine learning based on blockchain technology for drone security communication was proposed [23]. The method utilized 3L-BC three-level blockchain architecture, collaborative learning and consensus algorithms. The result was the throughput of 5700 TPS, latency of 0.2567 seconds, and processing time of 0.475 seconds. Intrusion detection in smart grids by using ensemble models was investigated. The method applied intelligent ensemble learning for detecting cyber threats in the smart-grid environment [24]. The result improved the detection of smart-grid cyber threats, but no specific numeric values were provided in the available notes. Fog-based federated learning approach for IIoT intrusion detection was suggested [25]. The method applied CNN algorithm, federated learning, and fog computing for detecting jamming and spoofing attacks. The result was 93.4% accuracy on Edge-IIoTset dataset and 95.8% accuracy on CIC-IDS2017. The above figure 2, reflects the yearly trend of publications of the selected papers on fog computing during 2023 to 2026. It is apparent from the graph that there have been most papers published in 2025, highlighting the current popularity of research work on fog computing, AI scheduling,

security, and IoT applications. The lesser number of papers in 2026 can be because of the recent year. In the above figure 3, the distribution of selected papers has been presented based on fog computing domains. The domain that had the most number of studies was resource management and task scheduling, followed by security, privacy, trust management, threat detection, and federated defense. It can be observed from the graph that recent fog computing studies concentrated more on optimization and security.

DISCUSSION

According to the literature review, it should be noted that the most important advances in developing fog computing technologies for improving the IoT applications relate to the problem of resource management, task scheduling and the issues of security. Application of AI including such types of AI as deep learning, reinforcement learning and fuzzy logic make it possible to optimize the resources and decrease the latency. In turn, blockchain technology, federated learning and zero-trust models increase the security and reliability of communication. Nevertheless, there are problems in terms of high computational requirements, scalability, privacy and implementation of technologies in real-time situations. However, use of light AI algorithms and secure architecture increases the efficiency of fog computing systems.

CONCLUSION

It is established through this review that fog computing has developed into an intense field of survey for the delivery of secure and efficient IoT services. Through the analysis of 30 papers, it is clear that the application of AI scheduling, machine learning, deep learning, reinforcement learning, fuzzy logic, blockchain, zero trust, federated learning, and optimization has greatly contributed to the efficiency of resources, task offloading, security, health monitoring, industry automation, and smart city intelligence. It is clear from the findings that resource management and task scheduling have been the key areas of study, followed by security and federated threat detection. Results like increased energy savings, decreased latency, improved intrusion detection, better reliability, and more efficient authentication performance make it clear about the practicality of intelligence-based fog computing. Nevertheless, limitations are still prevailing within the field, which include scalability, communication overhead, computational expense, heterogeneity, privacy preservation, and adaptivity to real time.

Table 1: Background survey on Fog Computing Security, Threats Detection, and Internet of Things Applications

Authors, Year, Ref. No.	Concept	Method Used	Limitations	Results
Ashfaq et al. (2025) [21]	Real-time zero-trust attack detection in 5G edge networks was studied.	Machine learning-based attack prediction using KNN and SVM models was used within SDN-enabled 5G edge environments.	The approach mainly focused on 5G edge networks, while scalability for heterogeneous fog networks and adaptive attack detection required further study.	The framework achieved high accuracy and F1-score for real-time zero-trust attack prediction, but exact numerical values were not specified here.
Hamad et al. (2025) [22]	Federated learning approaches for intrusion detection in IoT environments were systematically analyzed.	Federated learning-based intrusion detection methods were reviewed for privacy-preserving and distributed IoT security.	The reviewed approaches still faced challenges related to communication cost, model convergence, heterogeneous IoT devices, and large-scale deployment.	The survey summarized the effectiveness of federated learning for IoT intrusion detection, but exact numerical result values were not specified here.
Goh et al. (2025) [23]	Blockchain-based collaborative machine learning for secure drone communication was developed.	A 3L-BC three-layer blockchain architecture was used with collaborative machine learning, blockchain consensus, and secure communication mechanisms.	The framework required further evaluation under highly dynamic drone networks, energy-constrained devices, and large-scale distributed environments.	The framework achieved 5700 TPS throughput, 0.2567 s latency, 0.475 s processing time, and high accuracy.
Alsirhani et al. (2025) [24]	AI-based intrusion detection in smart grids was investigated.	Artificial intelligence-based ensemble modelling was used to detect cyber threats in smart-grid environments.	The model required further adaptation for real-time deployment in heterogeneous smart-grid and fog-enabled environments with changing attack patterns.	The ensemble-based intrusion detection model improved cyber-threat detection in smart grids, but exact numerical values were not specified here.
Rehman et al. (2025) [25]	Fog-enabled federated learning-based intrusion detection for IIoT was proposed.	FFL-IDS used CNN, federated learning, and fog computing to detect jamming and spoofing attacks while preserving data privacy.	Communication overhead, resource-constrained IIoT devices, and real-time industrial fog deployment required further optimization.	On Edge-IIoTset, it achieved 93.4% accuracy, 91.6% recall, 88% precision, 87% F1-score, and 87% specificity. On CIC-IDS2017, it achieved 95.8% accuracy, 94.9% precision, 94% recall, 93% F1-score, and 93% specificity.

Table 2: Comparison of Machine Learning Methods in Fog Computing

Authors, Year, Ref. No.	Concept	Method Used	Limitations	Results
Jin and Rezaeipanah (2025) [4]	Dynamic task allocation in fog computing was studied.	Enhanced fuzzy logic was used to handle uncertainty in task allocation and fog resource decision-making.	Large-scale real-time fog validation was still required.	The method improved task allocation under uncertain fog conditions, but exact numerical values were not specified in the provided notes.
Jenifer and Angela JennifaSujana (2025) [8]	QoE-aware application deployment in fog computing was proposed.	ML-based ESCP framework was used to optimize application placement, resource utilization, and QoE requirements.	Highly dynamic fog environments with diverse workloads required further validation.	Bandwidth utilization improved by 5.2%, scalability by 3.2%, energy efficiency by 3.8%, response time by 2.1%, and prediction accuracy was maintained within +0.4%.
Kannan and Balasubramanian (2026) [14]	Secure ML-based fog healthcare framework was proposed.	Machine learning was used with fog computing to support privacy, data integrity, and secure healthcare prediction.	Practical large-scale implementation and real-time deployment required further study.	High prediction accuracy with low computational and communication costs was reported, but exact numerical values were not specified in the provided notes.
Ashfaq et al. (2025) [21]	Real-time zero-trust attack detection in 5G edge networks was studied.	KNN and SVM models were used in SDN-enabled 5G edge environments for malicious activity detection.	Scalability for heterogeneous fog networks and adaptive attack detection required further study.	High accuracy and F1-score were reported, but exact numerical values were not specified in the provided notes.
Alsirhani et al. (2025) [24]	AI-based intrusion detection in smart grids was investigated.	Ensemble machine learning modelling was used to detect cyber threats in smart-grid environments.	Real-time deployment in heterogeneous smart-grid and fog-enabled environments required further adaptation.	The ensemble-based intrusion detection model improved cyber-threat detection, but exact numerical values were not specified in the provided notes.

ABSTRACT

Zebrafish (Danio rerio) is a versatile vertebrate model in biomedical and pharmaceutical research owing to its genetic homology with humans, rapid development, optical transparency, cost-effectiveness, and suitability for high-throughput screening. This review summarizes zebrafish experimental methodologies, biomedical applications, and drug-screening potential in human disease research. Standardized maintenance, breeding, and disease-induction strategies are discussed for generating reliable and reproducible models. The review focuses on metabolic, neurological, cardiovascular, cancer, and toxicological applications, emphasizing conserved pathways including PI3K/Akt, AMPK, PPARs, MAPK, VEGF, and Nrf2 involved in disease progression and therapeutic responses. Biochemical, molecular, and histo pathological biomarkers for evaluating disease mechanisms and treatment outcomes are also discussed. The review also highlights zebrafish in drug discovery, where whole-organism screening enables simultaneous assessment of efficacy, toxicity, and pharmacokinetic responses through rapid, cost-effective high-throughput approaches. Advances in genetic engineering, automated imaging, and computational technologies have enhanced the translational relevance of zebrafish models. Although physiological and metabolic differences between zebrafish and humans remain limitations, technological

advances continue to expand their applicability in translational research. Overall, zebrafish provide a robust and efficient platform for understanding disease mechanisms, evaluating therapeutic interventions, and accelerating drug discovery, bridging in vitro studies and mammalian models in biomedical research.

Keywords: Zebrafish (*Daniorerio*), Disease models, Biomedical research, Drug discovery, Pharmacological screening, Metabolic disorders.

INTRODUCTION

Zebrafish is a small tropical freshwater vertebrate that has emerged as a highly valuable model organism in modern biomedical and pharmaceutical research due to its unique combination of genetic similarity, experimental flexibility, and physiological relevance to humans [1]. Over the past few decades, zebrafish have gained significant attention as an alternative to traditional mammalian models because of their rapid embryonic development, optical transparency during early developmental stages, and high fecundity, which collectively enable real-time visualization of developmental and pathological processes in living organisms [2]. From a genetic perspective, zebrafish exhibit a high degree of homology with humans, with nearly 70% of human genes having at least one zebrafish ortholog. In addition, many genes associated with human diseases are evolutionarily conserved, allowing researchers to reproduce disease conditions and investigate their molecular mechanisms effectively. The availability of advanced genetic techniques such as CRISPR/Cas9 genome editing and transgenic technologies has further strengthened the importance of zebrafish in functional genomics and disease-related studies [3].

Experimental Methodologies in Zebrafish Research

Maintenance and Breeding Conditions

Zebrafish are generally maintained in recirculating aquarium systems under controlled environmental conditions. The optimum water temperature is maintained at approximately 26–28°C with a pH of 7.0–7.5 and adequate dissolved oxygen levels. A 14:10 hour light-dark cycle is commonly used to regulate breeding and physiological activity. Adult zebrafish are usually fed with commercial dry feed, Artemia nauplii, or live food two to three times daily [4].

Disease Induction Methods

Various disease models can be established in zebrafish using dietary, chemical, genetic, and xenograft approaches. Metabolic disorders such as obesity and dyslipidemia are commonly induced using high-fat or high-cholesterol diets, while diabetes mellitus can be induced using chemicals such as streptozotocin or alloxan [5]. Neurological disorders including epilepsy and Parkinson's disease are induced using neurotoxic compounds such as pentylenetetrazol (PTZ), rotenone, or MPTP [6,7]. Cardiovascular abnormalities are generated using dietary modifications, cardiotoxic chemicals, or genetic manipulation, whereas cancer models are commonly developed through xenotransplantation of fluorescently labeled human cancer cells into zebrafish embryos [8].

Biomedical Applications of Zebrafish in Human Diseases and Disease-Specific Molecular Mechanisms

Metabolic disorders, including obesity, diabetes mellitus, dyslipidemia, and non-alcoholic fatty liver disease (NAFLD), are extensively studied in zebrafish due to the conservation of lipid and glucose metabolism pathways between zebrafish and humans [9].Experimental models are commonly established through high-fat diet feeding, overnutrition, or chemical induction, leading to obesity, hepatic steatosis, and hyperglycemia [10]. The phosphoinositide 3-kinase/protein kinase (PI3K/Akt) pathway is a key regulator of insulin signaling, glucose uptake, and glycogen synthesis. Impairment of PI3K/Akt signaling reduces glucose utilization and promotes lipid accumulation, thereby contributing to obesity and diabetes-like phenotypes in zebrafish [11]. AMP-activated protein kinase (AMPK) regulates fatty acid oxidation and energy homeostasis, while reduced AMPK activity promotes

lipogenesis and lipid accumulation [9]. In addition, peroxisome proliferator-activated receptors (PPAR-α and PPAR-γ) regulate lipid metabolism and adipogenesis, while adipokines such as leptin and adiponectin influence energy expenditure and insulin sensitivity [10].Oxidative stress and excessive ROS production contribute to insulin resistance and metabolic imbalance[11].Biochemical evaluation includes glucose, triglycerides, cholesterol, and oxidative stress markers, while histological assessment evaluates lipid deposition, adipocyte enlargement, and hepatic steatosis [12].

Neurological disorders in zebrafish involve oxidative stress, mitochondrial dysfunction, neuro inflammation, and neurotransmitter alterations [13]. Due to the conservation of major neurotransmitter systems and neuronal pathways, zebrafish has become a valuable model for studying neurodegenerative and neurobehavioral disorders, including Parkinson's disease, Alzheimer's disease, and epilepsy [14]. Experimental induction using neurotoxins such as MPTP, rotenone, and pentylenetetrazole (PTZ) produces behavioral and pathological features that closely resemble human neurological disorders [12,13].Oxidative stress and mitochondrial dysfunction contribute to neuronal injury. In Parkinson's disease models, dopaminergic neuronal degeneration is associated with reduced tyrosine hydroxylase activity, decreased dopamine synthesis, and impaired motor coordination [15,16]. In Alzheimer's disease models, accumulation of amyloid-β peptides and Tau-associated neurotoxicity promotes neuronal degeneration, cognitive impairment, and progressive synaptic dysfunction [17]. Neuroinflammation is also associated with activation of MAPK pathways, including JNK and p38 MAPK [18]. Neurotransmitter alterations and markers including BDNF, APP, α-synuclein, TH, AChE, and inflammatory mediators are commonly evaluated to assess neuronal integrity and disease progression [19].

Zebrafish cardiovascular models involve endothelial dysfunction, oxidative stress, inflammation, angiogenesis, and altered calcium signaling [20]. Experimental models are commonly established through high-cholesterol feeding, exposure to cardiotoxic agents, or genetic manipulation, resulting in pathological features such as vascular lipid accumulation, cardiac hypertrophy, arrhythmias, and impaired circulation [21].VEGF signaling regulates angiogenesis and vascular development, while its dysregulation contributes to abnormal vascular remodeling and endothelial dysfunction [22]. In addition, oxidative stress-induced activation of mitogen-activated protein kinase (MAPK) signaling pathways promotes endothelial injury and inflammatory responses, Oxidative stress-induced MAPK activation promotes endothelial injury and inflammatory responses [23]. Inflammatory mediators, particularly tumor necrosis factor-alpha (TNF-α) and other pro-inflammatory cytokines, further exacerbate endothelial dysfunction and vascular remodeling. Calcium signaling is another critical regulator of cardiovascular homeostasis, as alterations in intracellular calcium handling impair cardiac contractility, electrical conduction, and heart rhythm, leading to conditions such as arrhythmia and cardiac hypertrophy [24].Evaluation includes cholesterol, oxidative stress and inflammatory markers, along with VEGF, TNF-α and eNOS. Functional assessment includes heart rate, blood flow and vascular imaging, while histology evaluates vascular lipid deposition, endothelial damage and cardiac remodeling [25, 26].

Cancer progression in zebrafish models is characterized by uncontrolled cellular proliferation, resistance to apoptosis, angiogenesis, invasion, and metastasis. Both transgenic and xenograft cancer models exhibit conserved oncogenic pathways, making zebrafish a valuable system for investigating tumor biology and disease progression[27].Among the major molecular regulators, the phosphoinositide 3-kinase/protein kinase B (PI3K/Akt) and mitogen-activated protein kinase (MAPK) signaling pathways play central roles in tumor development. Aberrant activation of PI3K/Akt signaling promotes cell survival and proliferation, whereas MAPK signaling contributes to tumor growth [28]. In addition, vascular endothelial growth factor (VEGF)-mediated angiogenesis supports tumor expansion and contributes to tumor invasion and metastatic dissemination [29]. Dysregulation of apoptosis-associated proteins also contributes significantly to cancer progression. Altered expression of tumor suppressor and apoptotic regulators, including p53, Bax, Bcl-2, and caspases, contributes to cancer progression [30]. Molecular and biochemical evaluation of zebrafish cancer models includes proliferation markers, angiogenic factors, apoptosis-related proteins, and oncogenic signaling molecules. Histopathological examination reveals tumor mass formation, abnormal cellular morphology, increased vascularization, tissue invasion, and metastatic lesions [23].

Toxicological responses in zebrafish are primarily associated with oxidative stress, making zebrafish an effective model for evaluating the safety and adverse effects of drugs, environmental pollutants, and industrial chemicals [30]. Exposure to toxic agents such as heavy metals, nanoparticles, pesticides, pharmaceuticals, and other environmental contaminants can induce excessive production of reactive oxygen species (ROS)[31].

A major protective mechanism against toxic insult involves the nuclear factor erythroid 2-related factor 2 (Nrf2) signaling pathway, which regulates cellular antioxidant defense systems. Under oxidative stress conditions, Nrf2 translocates to the nucleus and activates the expression of antioxidant and detoxification genes, thereby reducing oxidative injury and maintaining cellular homeostasis [32]. Toxicological studies commonly evaluate the expression of Nrf2-regulated genes, cytochrome P450 enzymes, heat shock proteins, inflammatory mediators, and oxidative stress biomarkers. Biochemical assessment frequently includes the measurement of ROS levels, antioxidant enzyme activities, and organ-specific injury markers such as liver enzymes. Histopathological examination further confirms toxicity through the detection of liver necrosis, neuronal degeneration, cardiac edema, tissue inflammation, spinal deformities, and developmental malformations [33].

Drug Screening Using Zebrafish

Zebrafish has emerged as a powerful platform for drug discovery and pharmacological screening due to its ability to integrate whole-organism physiology with molecular and cellular responses. Unlike in vitro systems, zebrafish allows in vivo evaluation of drug effects, enabling simultaneous assessment of efficacy, toxicity, and pharmacokinetic behavior within a single experimental model [34]. One of the key advantages of this system is the ability of zebrafish larvae to absorb compounds directly from the surrounding aquatic environment [35]. A major strength of zebrafish in drug screening lies in its compatibility with high-throughput screening approaches, where large numbers of embryos or larvae can be maintained in multi-well plates and exposed to different concentrations of test compounds simultaneously. This setup allows rapid identification of biologically active molecules and dose-dependent responses, making it highly suitable for early-stage drug discovery [36]. Importantly, zebrafish models enable real-time observation of morphological and physiological changes, which provides a significant advantage over traditional screening systems [37].

Zebrafish has been widely used for screening both natural and synthetic compounds across various disease models, particularly in metabolic, neurological, and cancer research [38]. The conserved nature of biochemical pathways, including lipid metabolism and signaling cascades, allows zebrafish to produce responses that are often predictive of higher vertebrate systems, thereby enhancing its translational relevance [39].Toxic effects such as developmental abnormalities, organ damage, and behavioral alterations can be simultaneously monitored during drug exposure, allowing early identification of adverse effects [40]. Furthermore, biomarkers such as oxidative stress indicators, enzyme levels, and gene expression changes provide mechanistic insights into drug action and toxicity [7].Despite its advantages, certain challenges remain in zebrafish-based drug screening, particularly in translating dosage and pharmacokinetic data to human systems, as differences in metabolism and absorption may influence drug response [41].Advances in genetic tools, imaging, and automated screening continue to improve zebrafish-based drug discovery.

Future Perspectives

Advanced gene-editing techniques such as CRISPR/Cas9 enable precise disease modeling and may facilitate the development of personalized zebrafish models [34].In addition, the growing application of high-throughput screening combined with automated imaging systems is expected to improve the efficiency and accuracy of drug discovery processes. The incorporation of artificial intelligence and machine learning approaches into zebrafish-based screening platforms can facilitate rapid data analysis, pattern recognition, and prediction of drug responses, thereby enhancing the overall translational value of the model [42]. The development of more sophisticated disease models, including multi-disease and co-morbidity models, will provide a better understanding of complex human conditions that involve multiple physiological systems. Despite certain limitations related to differences in

physiology and drug metabolism between zebrafish and humans, ongoing improvements in experimental design and data interpretation are expected to overcome these challenges [43].

CONCLUSION

Zebrafish offers a unique advantage in drug discovery by combining efficacy and toxicity evaluation within a single experimental system. High-throughput screening and simple aquatic drug administration enable rapid identification of potential therapeutic compounds and assessment of their pharmacological effects. The correlation of zebrafish responses with higher vertebrate models further enhances its translational value as an intermediate platform between in vitro assays and mammalian studies. Despite limitations related to differences in drug metabolism and physiological complexity compared with humans, advances in genetic engineering, imaging, and analytical technologies continue to improve the reliability and applicability of zebrafish models. Overall, zebrafish represents a powerful, cost-effective, and translational model for understanding human diseases and supporting disease modeling, pharmacological screening, and development of novel therapeutic strategies.

ABSTRACT

Diabetes mellitus has emerged as one of the most prominent non-communicable diseases globally, impacting millions and placing a considerable strain on healthcare systems. The prevalence of diabetes is rapidly increasing in India due to shifts in lifestyle, urbanization, sedentary habits, unhealthy dietary patterns, and genetic predisposition. Effective management of diabetes relies not only on medical treatment but also on the knowledge, attitudes, and self-care practices of patients. The current study aims to assess and compare the knowledge, attitudes, and practices (KAP) related to diabetes mellitus among rural and urban patients in Kumbakonam Taluk. The study seeks to identify differences in awareness levels, perceptions, lifestyle modifications, adherence to medication, dietary habits, physical activity, and regular health monitoring between the two populations. A descriptive comparative research design is adopted, utilizing a structured questionnaire administered to diabetic patients attending selected healthcare institutions. Statistical tools such as percentage analysis, Chi-square test, independent sample t-test, correlation analysis, and regression analysis are employed to analyze the collected data. The findings are expected to provide valuable insights into the disparities between rural and urban diabetic patients and assist healthcare professionals and policymakers in

designing targeted educational interventions, community awareness programs, and effective diabetes management strategies to improve patient outcomes and quality of life.

Keywords: Diabetes Mellitus**,** Knowledge, Attitudes, and Practices (KAP)**,** Rural and Urban Patients**,** Diabetes Self-Management**,** Kumbakonam Taluk

INTRODUCTION

Diabetes mellitus is a chronic metabolic condition marked by elevated blood glucose levels due to defects in insulin secretion, insulin action, or both. It represents one of the most rapidly escalating public health issues worldwide and has emerged as a significant cause of morbidity and mortality. The International Diabetes Federation (IDF) reported that in 2021, over 537 million adults globally were living with diabetes, with projections indicating a substantial increase in the coming decades. India, often dubbed the "Diabetes Capital of the World," has one of the largest populations of diabetics globally. Factors such as rapid urbanization, lifestyle changes, an aging population, unhealthy eating habits, obesity, lack of physical activity, and heightened stress levels have significantly contributed to the rising diabetes burden in the country. Diabetes mellitus is generally categorized into Type 1 diabetes, Type 2 diabetes, gestational diabetes, and other specific forms. Among these categories, Type 2 diabetes constitutes approximately 90–95% of all diabetes cases and is mainly linked to lifestyle and behavioral risk factors. Unlike infectious diseases, diabetes necessitates lifelong management, which includes regular medication, blood glucose monitoring, and adherence to healthy dietary practices, physical activity, and consistent medical follow-up. Inadequate glycaemic control can lead to severe complications, including cardiovascular diseases, kidney failure, diabetic retinopathy, neuropathy, diabetic foot ulcers, and premature death.

The management of diabetes encompasses more than just pharmacological interventions. Effective control of the condition significantly relies on patients' awareness, perceptions, attitudes, and daily health practices. Understanding the disease allows individuals to grasp its causes, symptoms, complications, treatment options, and preventive strategies. Positive attitudes motivate patients to follow prescribed medications, embrace healthy lifestyles, and engage actively in managing their condition. Essential practices such as consistent blood sugar monitoring, balanced nutrition, physical activity, foot care, adherence to medication, and regular health check-ups play a crucial role in minimizing complications related to diabetes. The Knowledge, Attitude, and Practice (KAP) model has emerged as a widely recognized framework in public health research for evaluating the behavioral factors that affect disease prevention and management. Knowledge pertains to the understanding that individuals have about a disease. Attitude encompasses beliefs, perceptions, and the readiness to adopt healthy behaviors. Practice signifies the actual execution of preventive and therapeutic actions in everyday life. Evaluating these three aspects offers a thorough insight into patient behavior and aids in pinpointing areas that require educational intervention. India faces distinct challenges in diabetes management due to its extensive socioeconomic, cultural, educational, and geographical diversity. There are significant differences between rural and urban populations regarding healthcare access, educational opportunities, income levels, lifestyle choices, occupational patterns, and exposure to health information. Urban dwellers typically enjoy better access to healthcare services, diagnostic facilities, specialists, and educational resources. However, they are also more prone to adopting sedentary lifestyles, consuming processed foods, and experiencing occupational stress, all of which elevate the risk of diabetes.

In contrast, rural populations frequently face obstacles such as insufficient healthcare infrastructure, a lack of available specialists, inadequate transportation options, lower literacy levels, and diminished awareness regarding the prevention and management of diabetes. While individuals in rural communities may participate in more physical activity due to agricultural work, factors such as delayed diagnosis, poor adherence to treatment, and insufficient follow-up care often lead to worse health outcomes. These differing characteristics underscore the significance of comparative studies between diabetic populations in rural and urban areas. Over the last twenty

years, Tamil Nadu has experienced a notable rise in the prevalence of diabetes. Factors such as increased life expectancy, economic growth, and shifts in dietary habits, decreased physical activity, and rising obesity rates have contributed to the spread of diabetes in both urban and rural locales. Kumbakonam Taluk, situated in the Thanjavur district of Tamil Nadu, showcases a diverse demographic that includes rapidly growing urban centers alongside numerous rural villages. Healthcare services are delivered through government hospitals, primary health centers, private hospitals, diabetic clinics, and community health initiatives. However, disparities in health literacy and access to medical resources continue to affect diabetes management for patients living in various environments. Patient education has become a vital aspect of diabetes management. Research indicates that individuals with a solid understanding of diabetes tend to demonstrate greater adherence to medication, achieve better glycaemic control, adopt healthier dietary practices, and experience fewer complications. Furthermore, a positive outlook towards lifestyle changes significantly enhances long-term health outcomes. Nevertheless, mere awareness does not always lead to the adoption of suitable health behaviours. Factors such as financial limitations, societal beliefs, cultural customs, lack of family support, and access to healthcare frequently impact patients' actions. Healthcare professionals are instrumental in promoting diabetes awareness through counselling, health education, lifestyle modification programs, nutritional advice, and ongoing follow-up. Community health workers, nurses, pharmacists, and physicians play a significant role in enhancing patients' self-management capabilities. Government initiatives, such as the National Programme for Prevention and Control of Non-Communicable Diseases (NP-NCD), have bolstered diabetes screening, early diagnosis, and health promotion efforts throughout India. Despite these initiatives, there remain notable disparities in diabetes knowledge and self-care practices between rural and urban populations.

A comparative evaluation of knowledge, attitudes, and practices (KAP) among diabetic patients provides valuable insights for creating targeted interventions. Rural communities may need a stronger focus on awareness campaigns, screening events, and improved healthcare access, while urban areas might benefit from programs that encourage lifestyle changes, stress management, and obesity prevention. Such data aids policymakers in effectively distributing healthcare resources and formulating educational strategies tailored to specific communities. This study aims to assess the knowledge, attitudes, and practices related to diabetes mellitus among patients in both rural and urban settings within Kumbakonam Taluk. By examining the similarities and differences between these two groups, the research enhances the understanding of the behavioral factors that affect diabetes management. The results are anticipated to aid healthcare providers, government bodies, and public health professionals in creating targeted educational programs that enhance self-management practices, minimize complications, and improve the overall quality of life for individuals with diabetes. Ultimately, increasing patient awareness and encouraging healthy behavioral practices are essential elements in alleviating the rising burden of diabetes and achieving sustainable public health results.

Statement of the Problem

Diabetes mellitus has emerged as a significant public health issue in India, with its prevalence rising among both rural and urban populations. Despite considerable advancements in medical facilities and treatment options, effective management of diabetes largely relies on patients' understanding, attitudes, and self-care practices. Insufficient awareness regarding the symptoms of the disease, risk factors, adherence to medication, dietary management, physical activity, and prevention of complications often results in poor glycaemic control and escalated healthcare expenses. There are notable disparities between rural and urban populations concerning healthcare accessibility, educational levels, socioeconomic conditions, and exposure to health information. Urban patients typically enjoy better access to healthcare but are more prone to sedentary lifestyles and unhealthy eating habits. Conversely, rural patients often face delays in diagnosis, limited access to specialized care, and inadequate health education. These variations may affect patients' approaches to diabetes management. Although numerous government initiatives have been launched to enhance diabetes awareness, there is a lack of comparative evidence regarding the knowledge, attitudes, and practices of diabetic patients in Kumbakonam Taluk. Gaining insight into these differences is crucial for formulating effective community-based interventions. Consequently, this study aims to assess and compare the knowledge, attitudes, and practices related to diabetes mellitus among rural and urban

patients in Kumbakonam Taluk, with the goal of identifying gaps and proposing strategies to enhance diabetes management and overall patient well-being.

Logical Background

The Knowledge, Attitude, and Practice (KAP) framework serves as a theoretical foundation for assessing behaviors related to diabetes. This model posits that possessing sufficient knowledge about diabetes fosters positive attitudes, which in turn encourage healthy self-care practices, including adherence to medication, maintaining a balanced diet, engaging in regular physical activity, monitoring blood glucose levels, and attending periodic medical check-ups. Nevertheless, factors such as socioeconomic status, educational attainment, access to healthcare, and cultural beliefs can significantly influence these dynamics. By comparing diabetic patients in rural and urban settings, researchers can uncover differences in behaviorand identify gaps in healthcare. The results can inform evidence-based interventions designed to enhance diabetes awareness, promote healthy lifestyles, improve adherence to treatment, and mitigate diabetes-related complications in Kumbakonam Taluk.

REVIEW OF LITERATURE

Singh et al. (2022) performed a comparative analysis of diabetic patients in rural and urban settings in Uttar Pradesh. The urban participants exhibited a notably higher level of awareness concerning diabetes complications, foot care, and blood glucose monitoring compared to their rural counterparts. The authors underscored the necessity for targeted awareness initiatives within rural communities. Rani and Kumar (2022) examined medication adherence among diabetic patients in Tamil Nadu. Their findings revealed that factors such as patient education, family support, and consistent counselling from healthcare providers significantly impacted medication compliance. Rural participants indicated facing greater financial obstacles to treatment. The National Family Health Survey (NFHS-5) (2022) reported a rising prevalence of diabetes among adults in India, especially among those leading sedentary lifestyles and experiencing obesity. The survey advocated for the expansion of screening and awareness programs in both rural and urban demographics. Prasad et al. (2023) explored diabetes self-care practices among patients visiting tertiary hospitals in Karnataka. Those who received structured diabetes education showed significantly improved dietary management, physical activity, and adherence to medication compared to patients who only received standard care. Balaji et al. (2024) evaluated diabetes awareness among patients at Primary Health Centres in Tamil Nadu. The study revealed that while most patients acknowledged diabetes as a chronic condition, their understanding of complications such as diabetic nephropathy and retinopathy was still lacking. Continuous education for patients was recommended. The Indian Council of Medical Research (ICMR) (2025) indicated a growing prevalence of diabetes in semi-urban and rural areas of India. The report emphasized the need to incorporate diabetes education into primary healthcare services and to enhance community-based lifestyle intervention programs.

Objectives

- To investigate the socio-demographic characteristics of diabetes mellitus patients in both rural and urban settings within Kumbakonam Taluk.
- To evaluate the understanding of diabetes mellitus among patients residing in rural and urban areas.
- To assess the perspectives of rural and urban patients regarding the prevention, treatment, and self-management of diabetes.
- To examine the self-care practices related to diabetes, such as adherence to medication, dietary choices, physical activity, blood glucose monitoring, and consistent medical follow-up among patients in rural and urban environments.

Research Questions

1. What socio-demographic characteristics are present among rural and urban patients diagnosed with diabetes mellitus in KumbakonamTaluk?

2. How knowledgeable are rural and urban patients regarding diabetes mellitus?
3. What are the attitudes of rural and urban patients towards the prevention, treatment, and self-management of diabetes?
4. What diabetes-related self-care practices are adopted by rural and urban patients?
5. Is there a notable difference in the knowledge of diabetes mellitus between rural and urban patients?
6. Is there a significant difference in attitudes towards diabetes management between rural and urban patients?
7. Is there a significant difference in diabetes self-care practices between rural and urban patients?
8. Is there a significant correlation between socio-demographic characteristics and the knowledge, attitudes, and practices of diabetic patients?
9. What is the connection between knowledge, attitudes, and self-care practices among diabetic patients?
10. Which factors have a significant impact on diabetes management practices among rural and urban patients in Kumbakonam Taluk?

Overall Interpretation of the Findings

The current study assessed the knowledge, attitudes, and practices (KAP) related to diabetes mellitus among 300 participants, consisting of 150 rural and 150 urban patients from Kumbakonam Taluk. The results offer a thorough insight into the socio-demographic characteristics of the respondents and highlight notable differences between rural and urban diabetic patients regarding awareness, perceptions, and self-management practices. The demographic evaluation revealed that male respondents (52.3%) slightly exceeded female respondents (47.7%). The age distribution indicated that the largest segment of participants (30.0%) fell within the 51–60 years age range, followed by 27.3% in the 41–50 years category. This observation implies that diabetes mellitus is more common among middle-aged and older individuals, aligning with the natural progression of Type 2 diabetes linked to aging, sedentary lifestyles, and metabolic changes. Educational attainment varied significantly between rural and urban respondents. Urban patients typically had higher educational qualifications, while a larger proportion of rural respondents had only primary education or were illiterate. Education is crucial for understanding disease management, and this gap may account for the differences in diabetes awareness and self-care practices observed.

The duration of diabetes indicated that nearly one-third (31.0%) of the respondents had been diagnosed with diabetes for two to five years, suggesting that many participants were in the initial stages of long-term disease management. Ongoing education during this time is vital to prevent complications and enhance quality of life.The examination of knowledge levels revealed a distinct disparity between rural and urban populations. While 49.3% of urban patients demonstrated a strong understanding of diabetes, only 22.7% of rural respondents achieved this level of knowledge. In contrast, the prevalence of poor knowledge was significantly higher among rural patients. This observation indicates that urban residents have greater access to healthcare services, health information, educational programs, and specialist consultations. Rural patients may encounter limited opportunities for structured diabetes education, leading to diminished awareness regarding disease prevention and management. A similar trend was noted in the levels of attitudes. Urban respondents exhibited more favorable attitudes towards diabetes management, while rural participants were more inclined to display neutral or negative attitudes. Positive attitudes are crucial as they encourage patients to adhere to medical advice, embrace healthier lifestyles, and engage actively in disease management. The comparatively lower positive attitude among rural patients highlights the necessity for behavioural counseling and community-oriented health education programs. Findings related to practice further corroborated these disparities. Urban patients reported superior diabetes self-management practices, such as regular blood sugar monitoring, physical activity, and adherence to medication. Although 63.3% of all respondents consistently adhered to their prescribed medication regimen, urban participants demonstrated higher compliance than their rural counterparts. Similarly, regular exercise and routine blood glucose monitoring were more prevalent among urban patients, indicating enhanced awareness and accessibility to healthcare. These healthy practices play a significant role in improving glycaemic control and minimizing diabetes-related complications. The inferential statistical analysis provides robust support for these findings.

Independent sample t-tests indicated statistically significant differences in knowledge, attitude, and practice scores between respondents from rural and urban areas ($p < 0.001$), thereby confirming that the place of residence has a substantial impact on diabetes-related awareness and behavior. In a similar vein, Chi-square analysis revealed a significant correlation between residential location and KAP levels, suggesting that there are meaningful differences in diabetes-related characteristics between rural and urban populations. Pearson correlation analysis uncovered strong positive correlations among knowledge and attitude ($r = 0.61$), knowledge and practice ($r = 0.68$), and attitude and practice ($r = 0.58$). These results imply that enhanced knowledge correlates with more favorable attitudes and improved self-care practices. Patients with a deeper understanding of diabetes are more inclined to adopt healthy behaviors, including adherence to medication, dietary management, physical activity, and regular health monitoring. Furthermore, the multiple regression analysis confirmed that knowledge, attitude, and educational level are significant predictors of diabetes management practices, while age did not show a statistically significant effect. The regression model accounted for 59% of the variance in practice scores ($R^2 = 0.59$), indicating considerable explanatory strength. In conclusion, the study suggests that enhancing diabetes knowledge through patient education, fostering positive attitudes via counseling, and improving healthcare access, especially in rural regions, can significantly enhance diabetes self-management practices. These findings offer critical insights for healthcare professionals, policymakers, and public health authorities to develop targeted educational initiatives and community-based diabetes management programs aimed at mitigating rural–urban disparities and improving the overall health outcomes of diabetic patients in KumbakonamTaluk.

Suggestions

- Strengthen Community-Based Diabetes Education: Implement consistent awareness initiatives to enhance knowledge about diabetes and promote self-management.
- Improve Rural Healthcare Accessibility: Upgrade Primary Health Centres by providing advanced diagnostic tools, skilled personnel, and counselling services.
- Promote Lifestyle Modification: Advocate for nutritious diets, consistent physical activity, weight control, and cessation of smoking.
- Enhance Patient Counselling: Offer ongoing guidance regarding medication compliance, blood glucose tracking, and prevention of complications.
- Utilise Digital Health Technologies: Encourage the use of mobile applications, telehealth services, and SMS notifications to aid in diabetes management.
- Increase Family and Community Participation: Engage families and communities in supporting diabetes care and fostering healthy lifestyle choices.
- Conduct Regular Screening Camps: Arrange periodic free diabetes screening events for early identification and prompt treatment.
- Strengthen Health Literacy: Create straightforward educational resources in Tamil to boost awareness about diabetes.
- Improve Nutritional Education: Provide tailored dietary advice to promote healthy eating practices.
- Continuous Professional Training: Regularly update healthcare providers on patient-focused diabetes education and counselling.

Recommendations

- The Government of Tamil Nadu ought to enhance diabetes prevention and management initiatives under the National Programme for Prevention and Control of Non-Communicable Diseases (NP-NCD), particularly focusing on rural populations.
- Health authorities are encouraged to set up specialized diabetes education centers within government hospitals and Primary Health Centres to offer ongoing counseling and follow-up care.

- Local government entities and non-governmental organizations (NGOs) should work together to conduct awareness campaigns, health fairs, and community outreach initiatives that promote diabetes prevention and healthy living.
- Educational institutions must incorporate fundamental diabetes awareness and healthy lifestyle education into health programs at schools and colleges to foster early prevention and encourage healthy habits among youth.
- Employers, especially in both public and private sectors, should establish workplace wellness initiatives that promote regular health screenings, physical activity, balanced nutrition, and stress management.
- Regular monitoring and evaluation of diabetes awareness initiatives should be conducted to measure their effectiveness and pinpoint areas needing enhancement.
- The expansion of telemedicine and mobile healthcare services is essential to reach remote villages where access to specialized diabetes care is limited.
- It is crucial to ensure financial support and affordable access to diabetes medications, diagnostic tests, and glucose monitoring devices for economically disadvantaged individuals.
- Future diabetes management policies should embrace a patient-centered approach that takes into account cultural beliefs, educational levels, and socioeconomic factors when designing interventions.
- Additional multicenter research involving larger and more diverse populations should be undertaken to validate findings and bolster evidence-based diabetes control strategies at both district and state levels.

Concluding Observations

Diabetes mellitus remains a considerable public health issue, necessitating ongoing efforts from healthcare professionals, policymakers, and the community. This study assessed the knowledge, attitudes, and practices related to diabetes mellitus among patients in both rural and urban settings in Kumbakonam Taluk, revealing significant differences between the two groups. The results show that urban patients typically have a greater understanding of diabetes, more favorable attitudes, and superior self-management practices compared to their rural counterparts. These disparities are largely linked to differences in educational levels, access to healthcare, health literacy, and exposure to health information. Rural patients exhibited lower awareness of diabetes complications, adherence to medication, regular blood glucose monitoring, and lifestyle changes, underscoring the necessity for targeted educational programs. Statistical analyses confirmed notable differences in knowledge, attitudes, and practices between rural and urban respondents. Additionally, strong positive correlations were found between knowledge, attitudes, and diabetes management practices, suggesting that enhanced awareness leads to healthier behaviors and better disease management. The regression analysis further indicated that knowledge, attitudes, and educational attainment are critical factors influencing effective diabetes self-care. The study highlights that diabetes management should encompass more than just pharmacological treatment; it should also involve comprehensive patient education, behavioural counseling, nutritional advice, regular physical activity, and ongoing follow-up. Enhancing primary healthcare services, broadening diabetes education programs, and improving access to quality healthcare in rural regions are vital for mitigating health disparities and preventing complications related to diabetes. The results offer significant evidence for healthcare professionals, public health officials, and policymakers in the creation of effective diabetes awareness initiatives and community-based interventions. By fostering patient empowerment, enhancing health literacy, and promoting sustainable self-care practices, it is feasible to improve glycaemic control, decrease long-term complications, elevate quality of life, and reduce the overall impact of diabetes. Consequently, this study adds to the expanding knowledge base on diabetes management and provides practical guidance for formulating equitable and evidence-based public health strategies in Kumbakonam Taluk and comparable regions throughout India.

ABSTRACT

Background: Basketball shooting performance is sensitive to environmental constraints, yet the specific effect of defensive pressure on hook shot execution remains insufficiently examined. Objective: This study investigated the effects of graded defensive pressure on hook shot accuracy and scoring efficiency in university-level basketball players using a constraints-led framework. Methods: A repeated-measures experimental design was employed. Sixty (N = 60) male university-level basketball players performed ten hook shot attempts under three conditions: no defender, passive defender, and active defender. Hook shot accuracy (maximum 10 per condition) and a multidimensional performance score incorporating second-chance scoring (maximum 20 per condition) were assessed. One-way repeated-measures ANOVAs with Bonferroni-adjusted pairwise comparisons were conducted; effect sizes are reported as partial eta squared (η^2p). Results: Significant main effects of defensive pressure were observed for both hook shot accuracy, $F(2, 118) = 1046.14$, $p < .001$, $\eta^2p = .947$, and performance score, $F(2, 118) = 859.46$, $p < .001$, $\eta^2p = .936$. Hook shot accuracy declined by 20.57% under passive pressure and 41.52% under active pressure relative to baseline. Performance score declined by 23.08% and 46.23%, respectively. All Bonferroni pair wise comparisons were significant (all $p < .001$), demonstrating a clear dose–response relationship. Conclusion: Defensive pressure has a substantial and progressive negative effect on hook shot performance. Unopposed shooting assessments may overestimate game-level shooting ability. Coaches should incorporate graded defensive constraints into hook shot training and evaluation protocols.

Keywords: basketball; hook shot; defensive pressure; shooting accuracy; constraints-led approach; representative learning design; scoring efficiency

INTRODUCTION

Background and Context

Basketball is a dynamic, high-intensity intermittent team sport in which performance is determined by the continuous interaction of physical, technical, tactical, and perceptual–cognitive demands. During competitive play, athletes are required to repeatedly accelerate, decelerate, change direction, dribble, pass, defend, rebound, and shoot under changing spatial and temporal constraints. Because game situations are unpredictable and opponent-dependent, successful performance depends not only on the execution of isolated technical skills but also on the ability to adapt those skills to defensive pressure and match-specific demands (Scanlan, Dascombe, &Reaburn, 2012; Wen et al., 2018). Within this performance structure, shooting remains one of the most decisive technical actions because it directly contributes to scoring outcomes and match success. Shooting performance has received considerable attention in basketball research because successful shooting is strongly related to offensive effectiveness and team success. Basketball players execute different types of shots depending on distance from the basket, defender proximity, court location, body orientation, and tactical role. Common shot types include jump shots, lay-ups, dunks, tip-ins, and hook shots (Erčulj&Štrumbelj, 2015). Among these, the hook shot is a unique close-range shooting technique generally performed near the basket, particularly by post players and inside scorers. It is executed with the body positioned partly sideways to the basket, allowing the shooting arm to move in a sweeping action away from the defender. This body orientation enables the player to shield the ball and release it at a relatively high point, reducing the probability of being blocked. Therefore, the hook shot is especially relevant in congested, defended areas near the basket. The importance of shooting performance has resulted in considerable scientific attention directed toward understanding the factors that influence shot success. Previous investigations have examined shooting biomechanics, shooting accuracy, fatigue-induced changes in shooting performance, perceptual influences on shot execution, and the effects of defensive pressure on shooting effectiveness.

These studies have collectively demonstrated that shooting performance is influenced not only by technical proficiency but also by contextual variables such as opponent behavior, fatigue, environmental conditions, and psychological pressure. Consequently, contemporary basketball research increasingly recognizes that shooting performance should be evaluated within the context in which it is normally performed rather than under highly controlled laboratory conditions (van Maarseveen & Oudejans, 2018). Although the hook shot is tactically important, it has received limited direct research attention compared with jump shooting, free throws, lay-ups, and general shooting accuracy. Previous basketball shooting studies have primarily examined jump shot accuracy, fatigue-related changes, shooting mechanics, or general shot-type distributions. For example, research on shot types across competitive levels has shown that shot selection and shot success vary according to competition level, player type, and playing situation (Erčulj & Štrumbelj, 2015). Similarly, studies examining jump shooting have demonstrated that shooting accuracy can decline under increased physiological or task intensity, suggesting that shooting performance is sensitive to contextual and performance constraints (Marcolin et al., 2018). However, the specific effect of defensive pressure on hook shot execution remains insufficiently examined, despite the fact that the hook shot is commonly used in contested close-range situations. Traditional basketball skill assessment has often relied on standardized tests conducted under controlled and unopposed conditions. Such assessments are useful because they are simple, repeatable, and allow coaches to evaluate technical consistency. Several modern studies have supported the reliability and validity of basketball-specific skill tests, including combined skill tests, jump shooting accuracy tests, passing indices, dribbling tests, and basketball-specific fitness simulations (Boddington et al., 2019; Conte et al., 2018; Quílez-Maimón et al., 2021; Scanlan, Dascombe, &Reaburn, 2012). These studies have advanced basketball assessment by demonstrating the importance of test reliability, construct validity, and ecological relevance. Nevertheless, many traditional assessments still evaluate skills in isolation, without defensive interference, time pressure, or decision-making demands. This creates a potential gap between test performance and actual game performance. Contemporary sport science increasingly emphasizes the need for representative and ecologically valid testing environments. According to the representative learning design perspective, practice and assessment tasks should preserve the key informational and action constraints present in competitive performance (Pinder et al., 2011,

Fahmi et al. (2025)). In basketball, players rarely shoot in completely stable and unopposed conditions. Instead, they must perceive defender movement, adjust body position, regulate timing, and release the ball under spatial pressure. Therefore, unopposed shooting tests may overestimate actual competitive shooting ability. A more realistic assessment should include defensive constraints that reflect the demands of game play.

Defensive pressure is one of the most important environmental constraints influencing basketball skill execution. The presence of a defender can alter visual attention, reduce available space, increase time pressure, and disrupt movement coordination. Even passive defensive presence may affect a shooter by changing perceived space and forcing technical adjustment. Active defensive pressure creates an even greater challenge because the shooter must execute the skill while responding to a moving opponent attempting to contest or block the shot. Previous research has shown that defensive pressure can negatively affect basketball performance indicators such as passing, dribbling, and shooting effectiveness (Vencúrik et al., 2021; van Maarseveen & Oudejans, 2018). However, limited evidence is available regarding how different graded levels of defensive pressure influence hook shot accuracy and scoring efficiency. The constraints-led approach provides a useful theoretical framework for understanding this issue. From this perspective, skilled performance emerges from the interaction of individual, task, and environmental constraints(Dos Santos et al., 2020, Davids, Button, & Bennett, 2008). Defensive pressure can be understood as an environmental constraint that changes the functional movement solution available to the player. Under no-pressure conditions, the player may perform the hook shot with stable timing, body orientation, and release mechanics. Under passive pressure, the defender introduces visual and spatial interference. Under active pressure, the player must adapt rapidly to an opponent's movement, potentially altering release angle, release height, rhythm, and balance. Therefore, defensive pressure is expected to produce a graded decline in shooting performance. In addition to accuracy, basketball performance should be evaluated through broader indicators of scoring efficiency. Conventional shooting accuracy measures usually record only the success or failure of the first shot attempt. However, in real-game contexts, performance often includes second-chance opportunities, offensive rebounds, and recovery actions after a missed shot. A player who misses the initial hook shot but secures the rebound and scores may still contribute effectively to offensive success. Therefore, a multidimensional performance score that includes direct scoring and second-chance scoring may provide a more game-relevant assessment than accuracy alone. This approach aligns with recent calls for basketball skill assessments that capture not only isolated technical execution but also performance effectiveness under realistic constraints.

Despite the growing body of research on basketball skill testing, shooting assessment, defensive pressure, and ecological validity, a clear gap remains. Existing studies have examined jump shooting, passing, dribbling, change-of-direction ability, and general basketball performance tests, but few have specifically investigated hook shot performance under systematically manipulated defensive pressure. Furthermore, limited research has evaluated hook shot performance using both first-attempt accuracy and broader scoring efficiency. Addressing this gap may help coaches design better training drills and develop more realistic testing protocols for inside scoring situations. Previous research supports the notion that defensive pressure significantly affects basketball skill execution. Studies investigating shooting behavior have reported reductions in shooting efficiency when players perform under contested conditions compared with uncontested situations (van Maarseveen & Oudejans, 2018). Similarly, recent evidence examining shooting performance under fatigue and defensive interference has demonstrated significant alterations in shooting mechanics and reductions in shooting success rates when defensive pressure increases (Li et al., 2024). These findings suggest that shooting performance cannot be fully understood without considering the environmental constraints under which the skill is executed. Beyond shooting, evidence from passing and dribbling research further highlights the importance of contextual constraints. A comprehensive systematic review of basketball passing identified that passing performance should be assessed under variable and uncertain conditions because isolated assessments may not adequately reflect competitive performance (Quílez-Maimón et al., 2020). The review emphasized that technical skills in basketball emerge through interactions between players, opponents, and environmental demands, suggesting that representative assessment procedures are essential for obtaining meaningful performance information. Similar conclusions have been reported in studies examining basketball dribbling, agility, and multidirectional movement, where sport-specific testing environments consistently

demonstrate greater ecological relevance than isolated laboratory-based assessments (Conte et al., 2018; Boddington et al., 2019).

Ecological Validity and Representative Learning Design

One of the major criticisms of traditional sport skill testing is the limited ecological validity of many assessment protocols. Ecological validity refers to the extent to which a testing environment accurately represents the conditions encountered during actual competition. Traditional basketball skill tests frequently require players to perform shooting, passing, or dribbling tasks in isolation without the presence of defenders, tactical uncertainty, or decision-making demands. Although such procedures provide useful information regarding technical consistency, they may not accurately reflect performance during competition where athletes must continuously adapt to changing environmental constraints (Fahmi et al., 2025). Contemporary sport science increasingly advocates the use of representative learning design principles when assessing athletic performance. Representative learning design proposes that assessment and training tasks should preserve the key informational and action constraints present within the competitive environment. According to this perspective, athletes should be evaluated under conditions that closely resemble actual game situations so that measured performance reflects the perceptual, cognitive, and motor processes required during competition (Pinder et al., 2011). When assessment tasks fail to represent competitive conditions, there is a risk that performance outcomes will overestimate an athlete's true game effectiveness. This issue is particularly relevant in basketball because technical actions rarely occur under stable and predictable conditions. Players continuously interact with teammates, opponents, and tactical situations while making rapid decisions under time pressure. Consequently, basketball performance emerges from the interaction between the performer and the environment rather than from isolated technical execution alone. The importance of representative assessment has been highlighted in basketball passing research, where systematic review evidence suggests that technical skills should be evaluated under uncertain and variable conditions to obtain meaningful information regarding player performance (Quílez-Maimón et al., 2020). Similar recommendations have emerged from studies examining basketball dribbling, agility, shooting, and multidirectional movement assessments, all of which emphasize the importance of incorporating game-relevant constraints into testing procedures. Within the context of shooting assessment, ecological validity is particularly important because successful shooting requires the integration of perceptual information, decision-making processes, movement coordination, and technical execution. During actual competition, players must continuously adjust shot selection, release timing, body positioning, and force production in response to defender behavior. Therefore, assessments conducted without defensive interference may fail to capture critical determinants of shooting effectiveness. The inclusion of defensive pressure during shooting assessment may provide a more realistic evaluation of a player's ability to perform under competitive conditions.

Constraints-Led Approach and Defensive Pressure

The theoretical foundation of the present study is grounded in the Constraints-Led Approach (CLA), one of the most influential contemporary frameworks for understanding skill acquisition and performance in sport. Originally proposed by Newell (1986) and subsequently expanded by Davids, Button, and Bennett (2008), the Constraints-Led Approach suggests that movement behavior emerges from the interaction of three categories of constraints: individual constraints, task constraints, and environmental constraints. Individual constraints refer to characteristics of the performer, including physical attributes, technical ability, anthropometric characteristics, experience, and psychological factors. Task constraints include the specific objectives, rules, equipment, and movement requirements associated with a particular activity. Environmental constraints include external factors such as playing conditions, opponent behavior, spatial limitations, and social influences. According to this framework, skilled performance is not produced through a single optimal movement pattern but rather emerges through continuous adaptation to changing constraints (Davids et al., 2008). Within basketball, defensive pressure represents one of the most influential environmental constraints affecting technical performance. The presence of a defender alters the information available to the performer and modifies the movement solutions that can be effectively employed. Under low-pressure conditions, athletes may execute technical skills using relatively stable movement patterns. However, as defensive pressure increases, performers must adapt their actions to maintain effectiveness. This adaptation may

involve modifications in body positioning, movement timing, release mechanics, visual attention, and force production. The hook shot provides a particularly appropriate context for examining the influence of defensive constraints because it is typically executed in highly contested areas near the basket. During hook shot execution, offensive players must protect the ball from defensive interference while simultaneously maintaining balance, generating sufficient force, and accurately directing the ball toward the basket. As defender proximity increases, the performer may be required to modify movement characteristics to avoid a blocked shot, potentially increasing movement variability and reducing shooting effectiveness. Recent evidence indicates that defensive pressure can significantly influence basketball shooting kinematics and performance outcomes (Li et al., 2024; van Maarseveen & Oudejans, 2018). However, evidence specifically examining hook shot performance under systematically manipulated defensive pressure remains limited.

Multidimensional Assessment of Basketball Performance

Another limitation of traditional basketball skill assessment concerns the manner in which performance outcomes are quantified. Most shooting assessments rely exclusively on shooting accuracy, typically measured as the number of successful attempts relative to the total number of shots performed. Although accuracy remains an important indicator of technical proficiency, it may not fully capture performance effectiveness during actual competition. Basketball performance is inherently multidimensional. Successful offensive play depends not only on the ability to convert initial scoring opportunities but also on the capacity to respond effectively following unsuccessful attempts. Offensive rebounds, second-chance opportunities, recovery actions, and scoring persistence frequently contribute to successful offensive possessions. Consequently, a player who initially misses a shot but subsequently secures possession and converts a second scoring opportunity may contribute substantially to team performance despite recording a missed first attempt. Several researchers have argued that sport performance assessment should incorporate multiple indicators reflecting the complexity of competitive behavior rather than relying exclusively on isolated technical outcomes. Modern basketball performance evaluation increasingly incorporates multidimensional indicators that reflect tactical effectiveness, decision-making quality, and contextual performance outcomes (Conte et al., 2018; Boddington et al., 2019). Despite these developments, relatively few shooting studies have attempted to integrate second-chance scoring opportunities into performance assessment frameworks. To address this limitation, the present study introduces a performance score variable in addition to conventional hook shot accuracy. Whereas accuracy evaluates the success of the initial shot attempt, the performance score provides a broader measure of scoring efficiency by incorporating both direct scoring and second-chance scoring opportunities. This approach offers a more ecologically valid representation of offensive effectiveness and may provide additional insight into how defensive pressure influences overall scoring performance.

The available literature demonstrates substantial progress in the development of basketball skill assessments, shooting evaluation protocols, passing assessments, dribbling tests, and sport-specific performance measures. Previous studies have established the reliability and validity of numerous basketball-specific testing procedures, including shooting assessments, dribbling tests, passing indices, multidirectional movement assessments, and basketball-specific performance batteries (Boddington et al., 2019; Conte et al., 2018; Quílez-Maimón et al., 2020). Furthermore, recent investigations have highlighted the importance of representative learning design, ecological validity, and environmental constraints when evaluating athletic performance (Pinder et al., 2011; Davids et al., 2008). Despite these advances, several important gaps remain. First, the majority of basketball shooting research has focused on jump shots, free throws, and general shooting performance, with limited attention directed toward hook shot execution. Second, few studies have systematically manipulated multiple levels of defensive pressure to examine their effects on hook shot performance. Third, existing investigations have predominantly relied on conventional accuracy measures and have rarely incorporated broader indicators of scoring efficiency that account for second-chance opportunities. Finally, limited evidence exists regarding hook shot performance within a theoretical framework based on ecological validity and constraints-led principles. Therefore, further investigation is required to determine how graded defensive pressure influences hook shot performance and whether multidimensional performance indicators provide additional insight into offensive effectiveness under competitive constraints. The purpose of the present study was to examine the effects of graded defensive pressure on hook shot

accuracy and scoring efficiency in university-level basketball players. Defensive pressure was manipulated across three experimental conditions: no defender, passive defender, and active defender. Performance was evaluated using two dependent variables: hook shot accuracy and performance score.

METHODS

Study Design

The present study employed a repeated-measures experimental design to investigate the effects of graded defensive pressure on hook shot performance in university-level basketball players. A repeated-measures design was considered appropriate because all participants were exposed to each experimental condition, allowing individual performance differences to be controlled statistically while increasing the sensitivity of the analysis. The independent variable was defensive pressure, operationalized at three levels: (a) no defender, (b) passive defender, and (c) active defender. The dependent variables were hook shot accuracy and performance score. The study was designed in accordance with the principles of representative learning design and the constraints-led approach, which emphasize the importance of evaluating sport-specific skills under conditions that preserve key informational and environmental constraints present during competition (Dos Santos et al., 2020, Davids et al., 2008). Accordingly, defensive pressure was systematically manipulated to simulate progressively greater levels of game-like opposition. To minimize potential fatigue effects, standardized recovery intervals were provided between testing conditions. Furthermore, all testing procedures were conducted under identical environmental conditions, using the same basketball court, equipment, and testing personnel throughout the study.

Participants

A total of sixty (N = 60) male university-level basketball players voluntarily participated in the study. Participants were recruited from university basketball teams competing in inter-university and state-level competitions.

Inclusion Criteria

Participants were required to:

- Be male basketball players currently representing a university team.
- Have a minimum of three years of organized basketball playing experience.
- Be actively participating in regular basketball training at the time of data collection.
- Be free from musculoskeletal injury during the previous six months.

Exclusion Criteria

Participants were excluded if they:

- Reported any injury affecting shooting performance.
- Were unable to complete all testing sessions.
- Had any medical condition restricting participation in vigorous physical activity.

Prior to participation, all players were informed about the purpose, procedures, benefits, and potential risks of the study. Written informed consent was obtained from each participant before testing commenced.

Variables

Independent Variable

Defensive Pressure

Defensive pressure was operationally defined as the degree of opposition imposed by a defender during hook shot execution.

Three levels were established:

- **No-Pressure Condition:** Participants performed the hook shot without the presence of a defender. This condition represented the baseline assessment of shooting performance.

- **Passive-Defender Condition:** A defender was positioned close to the shooter but remained stationary and did not actively attempt to contest the shot. This condition introduced visual and spatial constraints while minimizing direct movement interference.
- **Active-Defender Condition:** The defender actively contested each hook shot by moving toward the shooter with raised arms and attempting to interfere with the shot trajectory. This condition was designed to replicate realistic defensive pressure encountered during competitive basketball play.

Dependent Variables

Hook Shot Accuracy

Hook shot accuracy was defined as the number of successful first-attempt hook shots completed out of ten attempts under each experimental condition. Each successful first attempt was awarded one point. The maximum possible score for each condition was ten points.

Performance Score

Performance score was developed as a multidimensional measure of scoring efficiency.

Scoring criteria were as follows:

- Successful first-attempt hook shot = 2 points
- Missed first attempt followed by successful rebound and score = 1 point
- Missed shot without subsequent score = 0 points

The maximum possible performance score under each condition was twenty points. This variable was included to provide a broader assessment of offensive effectiveness beyond conventional shooting accuracy measures.

Instrumentation and Equipment

All testing procedures were conducted on a standard indoor basketball court approved for competitive play. A standard basketball hoop (rim height = 3.05 m) and official size-7 basketballs approved by the International Basketball Federation (FIBA) were used throughout data collection. Court markings were used to ensure consistent positioning of participants during hook shot execution. Player height was measured using a portable stadiometer to the nearest 0.1 cm, while body mass was assessed using a calibrated digital weighing scale to the nearest 0.1 kg. Demographic information, including age and playing experience, was collected using a standardized participant information form. To ensure consistency across testing sessions, all measurements were conducted using the same equipment, by the same testing personnel, and under identical environmental conditions.

Hook Shot Testing Protocol

Prior to data collection, participants completed a standardized warm-up lasting approximately 15 minutes. The warm-up consisted of:

- 5 minutes of light jogging
- Dynamic stretching exercises
- Basketball-specific movement drills
- Practice hook shot attempts

Following the warm-up, participants received standardized instructions regarding testing procedures and scoring criteria. All hook shots were performed from a standardized location within the low-post area on the dominant side of the basket. Participants were instructed to execute a technically correct hook shot using their preferred shooting arm.

Each participant performed ten hook shot attempts under each of the three experimental conditions:

- No defender
- Passive defender
- Active defender

A total of thirty hook shot attempts were completed by each participant. For the no-pressure condition, participants executed the hook shot without the presence of a defender. For the passive-defender condition, a defender stood in

close proximity to the shooter but remained stationary throughout execution. For the active-defender condition, the defender actively attempted to contest the shot by moving toward the shooter with raised arms and simulating realistic defensive behavior commonly observed during competitive basketball play. Following a missed first attempt, participants were allowed to immediately secure the rebound and attempt a second scoring opportunity. These actions contributed to the performance score variable but were not included in the accuracy calculation.

Standardization Procedures

Several procedures were implemented to enhance internal validity and ensure consistency across participants. First, all participants performed the hook shot from the same court location and shooting distance. Second, the same basketball, basket, court surface, and testing environment were used throughout data collection. Third, the same defender performed all passive and active defensive conditions to ensure consistency in defensive behavior. To minimize fatigue effects, standardized recovery periods of approximately two minutes were provided between testing conditions. Participants were instructed to maintain maximal effort throughout all testing trials. Furthermore, all instructions were delivered using a standardized script to ensure procedural consistency.

Statistical Analysis

All statistical analyses were performed using IBM SPSS Statistics Version 29.0 (IBM Corp., Armonk, NY, USA). Prior to conducting inferential analyses, descriptive statistics, including means, standard deviations, minimum values, maximum values, and percentage changes, were calculated for all study variables. The assumption of normality was assessed using the Shapiro–Wilk test, supplemented by visual inspection of histograms and normal Q–Q plots. To examine the effects of graded defensive pressure on hook shot accuracy and performance score, separate one-way repeated-measures analyses of variance (ANOVA) were conducted. A repeated-measures design was considered appropriate because the same participants were assessed under all three experimental conditions (no pressure, passive defender, and active defender), thereby controlling for inter-individual variability and increasing statistical power. The assumption of sphericity was evaluated using Mauchly's Test of Sphericity, and where violations occurred, Greenhouse–Geisser corrections were applied to adjust the degrees of freedom. When significant main effects were identified, Bonferroni-adjusted pairwise comparisons were performed to determine specific differences between the no-pressure, passive-defender, and active-defender conditions. Statistical significance was established at $p < .05$. The magnitude of observed effects was assessed using partial eta squared (η^2p), interpreted according to Cohen's (1988) guidelines, where values of .01, .06, and .14 represented small, medium, and large effects, respectively. In addition, percentage changes between conditions were calculated to provide a practically meaningful interpretation of the magnitude of performance decline associated with increasing defensive pressure. All results are reported as mean ± standard deviation (M ± SD), together with F-values, exact p-values, 95% confidence intervals, and partial eta squared effect sizes where appropriate.

RESULTS

Participant Characteristics

A total of 60 university-level male basketball players participated in the study. The participants had a mean age of 21.52 ± 1.94 years, mean height of 185.72 ± 3.14 cm, mean body mass of 81.03 ± 3.99 kg, and an average playing experience of 7.38 ± 1.09 years. These characteristics indicate that the sample consisted of experienced competitive basketball players with relatively homogeneous anthropometric and playing backgrounds.

Inter-Rater Reliability

Inter-Rater Reliability Consideration

Inter-rater reliability analysis was not performed because the outcome variables used in the present study were based on objective and predefined scoring criteria rather than subjective evaluator judgments. Hook shot accuracy was recorded as successful or unsuccessful shot attempts according to predetermined criteria, while performance score was calculated using a standardized scoring system in which a successful hook shot was awarded two points, a

successful second-chance attempt was awarded one point, and unsuccessful attempts received zero points. Consequently, the recorded outcomes were not dependent on subjective interpretation by observers, thereby minimizing evaluator-related bias. Similar objective scoring procedures have been widely used in basketball performance research where measurement outcomes are directly observable and quantifiable. Therefore, inter-rater reliability was considered unnecessary for the present investigation.

Assessment of Normality

The assumption of normality was examined using the Shapiro–Wilk test for all dependent variables. Results indicated significant deviations from normality across most conditions ($p < .05$). Specifically, hook shot accuracy scores under no-pressure, passive-defender, and active-defender conditions, as well as performance scores under no-pressure and active-defender conditions, showed significant departures from normality. The performance score under the passive-defender condition was close to the threshold of significance ($p = .047$). However, repeated-measures ANOVA was retained because the sample size was relatively large ($N = 60$), and the procedure is considered robust against moderate violations of normality in within-subject designs.

Assessment of Sphericity

The assumption of sphericity was evaluated using Mauchly's Test of Sphericity prior to conducting the repeated-measures ANOVA. Results indicated that the assumption of sphericity was not violated for either hook shot accuracy or performance score ($p > .05$). Therefore, the original degrees of freedom were retained and standard repeated-measures ANOVA results were interpreted. Because Mauchly's Test was non-significant for both dependent variables, the assumption of sphericity was satisfied and no Greenhouse–Geisser correction was required**.**

Descriptive Statistics

Descriptive statistics for hook shot accuracy and performance score across the three defensive pressure conditions are presented in Tables 4 and 5

Effect of Defensive Pressure on Hook Shot Accuracy

A one-way repeated-measures ANOVA was conducted to determine whether hook shot accuracy differed significantly across the three defensive pressure conditions. The analysis revealed a statistically significant main effect of defensive pressure on hook shot accuracy, $F(2,118) = 1046.14$, $p < .001$. The magnitude of this effect was extremely large, indicating that a substantial proportion of variance in hook shot accuracy was explained by the level of defensive pressure. Visual inspection of Figure 1 demonstrated a systematic reduction in shooting accuracy from the no-pressure condition to the active-defender condition, confirming the presence of a graded performance decline. Bonferroni-adjusted pairwise comparisons revealed significant differences between all three experimental conditions (all $p < .001$).

Specifically:

- Hook shot accuracy was significantly higher in the no-pressure condition than in the passive-defender condition.
- Accuracy was significantly higher in the no-pressure condition than in the active-defender condition.
- Accuracy was also significantly higher in the passive-defender condition than in the active-defender condition.

These findings demonstrate that each incremental increase in defensive pressure produced a meaningful reduction in shooting performance.

Percentage Reduction in Hook Shot Accuracy

To provide a practically meaningful interpretation of the results, percentage changes relative to baseline performance were calculated. Compared with the no-pressure condition, hook shot accuracy decreased by approximately 20.6% under passive defensive pressure and by approximately 41.5% under active defensive pressure. The magnitude of decline observed under active defensive pressure was approximately double that observed under passive defensive pressure, highlighting the substantial disruptive influence of realistic defensive opposition on hook shot execution.

These findings indicate that even moderate defensive presence is sufficient to impair shooting performance, whereas active defensive contesting produces a dramatic reduction in accuracy.

DISCUSSION
